**Acentric Factor** The acentric factor of a compound ω is defined in terms of the reduced vapor pressure evaluated at a reduced temperature of 0.7 as

$$\omega = -\log P_r^*\Big|_{T_r = 0.7} - 1.0000 \qquad (2\text{-}19)$$

It is primarily used as a third parameter (in addition to $T_c$ and $P_c$) in CS predictions as a measure of deviations from nonspherical molecular shape, hence the name, suggesting molecular interactions that are not between centers of molecules. However, as defined in Eq. (2-19), ω also contains polarity information, and it increases with increasing polarity for molecules of similar size and shape. The value of ω is close to zero for small, spherically shaped, nonpolar molecules (argon, methane, etc.). It increases in value with larger deviations of molecular shape from spherical (longer chain lengths, less chain branching, etc.) and with increasing molecular polarity. When possible, ω should be obtained from experimental vapor pressure correlations by using Eq. (2-19), but an accurate estimation of ω can be made by using the critical constants and a single vapor pressure point by application of CS vapor pressure equations.

***Recommended Method 1*** Definition.

*Classification:* Theory and empirical extension of theory.

*Expected uncertainty:* Within 3 percent if an experimental vapor pressure correlation is available; within 10 percent from a predicted vapor pressure correlation.

*Applicability:* Most organic compounds.

*Input data:* Vapor pressure correlation or $T_c$, $P_c$, and $T_b$ if an experimental vapor pressure correlation is unavailable.

*Description:* Equation (2-19) is applied directly to the appropriate vapor pressure equation. A predictive vapor pressure equation can also be used as in the second example.

***Example*** Calculate the acentric factor of chlorobenzene with a known value for $T_b$.

*Input information:* From the DIPPR 801 database, $T_b$ = 404.87 K, $T_c$ = 632.35 K, and $P_c$ = 45.1911 bar.

*Calculation of auxiliary quantities (see Eq. (2-28a) for these equations):*

$$T_{br} = \frac{T_b}{T_c} = \frac{404.87}{632.35} = 0.64 \qquad K = 0.0838$$

$$\psi = -35 + \frac{36}{T_{br}} + 42 \cdot \ln(T_{br}) - T_{br}^6 = -35 + \frac{36}{0.64} + 42 \cdot \ln(0.64) - (0.64)^6 = 2.4312$$

$$\alpha_c = \frac{(3.758)K\psi + \ln(P_C / 1.01325\,\text{bar})}{K\psi - \ln(T_{br})}$$

$$= \frac{(3.758)(0.0838)(2.4312) + \ln\left(\frac{45.1911}{1.01325}\right)}{(0.0838)(2.4312) - \ln(0.64)} = 7.025$$

$$D = K(\alpha_c - 3.758) = (0.0838)(7.025 - 3.758) = 0.2738$$

$$A = 35D = 9.581 \quad B = -36D = -9.855 \quad C = \alpha_c - 42D = -4.473$$

*Calculation using Eq. (2-28) at $T_r$ = 0.7:*

$$\ln(P_r) = 9.581 - \frac{9.855}{0.7} - 4.473 \cdot \ln(0.7) + 0.2738 \cdot (0.7)^6 = -2.870$$

*Calculation using Eq. (2-19):*

$$\omega = -\frac{\ln(P_r)}{2.303} - 1.0000 = \frac{2.870}{2.303} - 1.0000 = 0.246$$

This value differs by −1.5 percent from DIPPR 801 recommended value of 0.2499.

***Recommended Method 2*** Corresponding states.

*Reference:* [PGL5].

*Classification:* Corresponding states.

*Expected uncertainty:* Generally within 5 percent, worse for strongly polar fluids.

*Applicability:* Most organic compounds.

*Input data:* $T_c$, $P_c$, and a single vapor pressure point (e.g., the normal boiling point $T_b$).

*Description:* See Eq. (2-29) for the equations used in this method. The vapor pressure equation is inverted to obtain the acentric factor from a single vapor pressure point.

***Example*** Repeat the above calculation of the acentric factor of chlorobenzene, using the Walton-Ambrose modification of the Lee-Kesler vapor pressure equation, Eq. (2-29).

*Input information:* From the DIPPR 801 database, $T_b$ = 404.87 K, $T_c$ = 632.35 K, and $P_c$ = 45.1911 bar.

*Calculation of auxiliary quantities:*

$$T_{br} = \frac{T_b}{T_c} = \frac{404.87}{632.35} = 0.64 \qquad \tau = 1 - 0.64 = 0.36$$

$$f^{(0)} = \frac{(-5.97616)(0.36) + (1.29874)(0.36)^{1.5} - (0.60394)(0.36)^{2.5} - (1.06841)(0.36)^5}{0.64}$$
$$= -3.0034$$

$$f^{(1)} = \frac{(-5.03365)(0.36) + (1.11505)(0.36)^{1.5} - (5.41217)(0.36)^{2.5} - (7.46628)(0.36)^5}{0.64}$$
$$= -3.1788$$

$$f^{(2)} = \frac{(-0.64771)(0.36) + (2.41539)(0.36)^{1.5} - (4.26979)(0.36)^{2.5} - (3.25259)(0.36)^5}{0.64}$$
$$= -0.037$$

*Calculation using Eq. (2-29) at the normal boiling point:*

$$\ln\frac{1.01325}{45.1911} = -3.798 = f^{(0)} + \omega f^{(1)} + \omega^2 f^{(2)} = -3.0034 - 3.1788\omega - 0.037\omega^2$$

*Back solution of the quadratic equation for* $\omega$: $\omega = 0.249$

**Radius of Gyration** The radius of gyration $R_g$ is a measure of the mass distribution about the center of mass of a molecule. Radius $R_g$ increases with molecular size. It is useful in CS applications to separate molecular size and shape effects from polar effects. It is defined in terms of the principal moments of inertia of a molecule (*A, B,* and *C*) as

$$R_g = \sqrt{\frac{(AB)^{1/2} N_A}{M}} \tag{2-20}$$

for planar molecules and as

$$R_g = \sqrt{\frac{2\pi(ABC)^{1/3} N_A}{M}} \tag{2-21}$$

for nonplanar molecules. Radii of gyration can be calculated from these defining equations using principal moments of inertia obtained from spectral data or from computational chemistry software.

***Recommended Method*** Principal moments of inertia.

*Classification:* Computational chemistry.

*Expected uncertainty:* Less than 5 percent.

*Applicability:* All molecules.

*Input data: M* and molecular structure.

*Description:* Computational chemistry software is used to optimize the geometry of the molecule and obtain the principal moments of inertia to be used in Eqs. (2-20) and (2-21).

***Example*** Calculate the radius of gyration for hydrazine.

*Input information:* From the DIPPR 801 database, $M = 32.0452$ kg/kmol. The structure of hydrazine is

$$H_2N—NH_2$$

*Calculation of the principal moments of inertia:* Optimizing hydrazine with HF/6-31G model chemistry gives the following principal moments of inertia:

$A = 12.24050 \text{ amu} \cdot \text{Bohr}^2$

$B = 72.41081 \text{ amu} \cdot \text{Bohr}^2$

$C = 79.16893 \text{ amu} \cdot \text{Bohr}^2$

*Conversion from atomic units to SI gives*

$$A = (12.24050 \text{ amu} \cdot \text{Bohr}^2)\left(\frac{5.29177\times10^{-11}\text{ m}}{\text{Bohr}}\right)^{-2}\left(\frac{1.66054\times10^{-27}\text{ kg}}{\text{amu}}\right)$$
$$= 5.692\times10^{-47}\text{ kg}\cdot\text{m}^2$$

$$B = (72.41081 \text{ amu} \cdot \text{Bohr}^2)\left(\frac{4.65010^{-48}\text{ kg}\cdot\text{m}^2}{\text{amu}\cdot\text{Bohr}^2}\right) = 3.367\times10^{-46}\text{ kg}\cdot\text{m}^2$$

$$C = (79.16893 \text{ amu} \cdot \text{Bohr}^2)\left(\frac{4.65010^{-48}\text{ kg}\cdot\text{m}^2}{\text{amu}\cdot\text{Bohr}^2}\right) = 3.681\times10^{-46}\text{ kg}\cdot\text{m}^2$$

*Calculation using Eq. (2-21):*

$$(ABC)^{1/3} = [(5.692\times10^{-47})(3.367\times10^{-46})(3.681\times10^{-46})]^{1/3}\text{ kg}\cdot\text{m}^2$$
$$= 1.918\times10^{-46}\text{ kg}\cdot\text{m}^2$$

$$R_g = \sqrt{\frac{2\pi\,(1.918\times10^{-46}\text{kg}\cdot\text{m}^2)(6.022\cdot10^{26}\text{kmol}^{-1})}{32.0452\text{ kg/kmol}}} = 1.505\times10^{-10}\text{ m}$$

This is 3.8 percent below the DIPPR 801 database value of $1.564 \times 10^{-10}$ m which was obtained from spectral principal moments of inertia.

**Dipole Moment** The dipole moment of a molecule is the first moment of the electric charge density expansion. All normal paraffins have a value of zero. Charge separation within the molecule due to electronegativity differences between bonded atoms increases the dipole moment. Computational chemistry software uses the electron density distribution of the optimized molecule to calculate dipole moments.

***Recommended Method*** Electron density distribution.

*Classification:* Computational chemistry.

*Expected uncertainty:* Uncertainty varies depending upon the model chemistry chosen, but it can be as large as 60 percent.

*Applicability:* All molecules.

*Input data:* Molecular structure.

***Example*** Calculate the dipole moment for methanol.

*Draw structure and optimize molecule by using computational chemistry software:* The dipole moment obtained from a geometry optimized with the HF/6-31G model chemistry for methanol is 2.288 D. This value is 35 percent larger than the experimental gas-phase value of 1.700 D in the DIPPR 801 database.

**Refractive Index** Refractive index is the ratio of the speed of light in a vacuum to the speed of light in the medium. The incident light is the sodium D line ($5.896\times10^{-7}$ m). Refractive index is dimensionless and generally ranges between 1.3 and 1.5 for organic liquids.

***Recommended Method*** Wildman-Crippen method.

*Reference:* Wildman, S. A., and G. M. Crippen, *J. Chem. Inf. Comput. Sci.* **39** (1999): 868.

*Classification:* Theory and group contribution.

*Expected uncertainty:* Generally less than 3 percent for liquids.

*Applicability:* Most organic molecules (currently not applicable to organic acids).

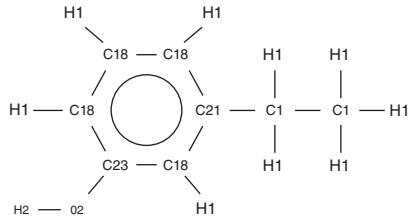
*Input data:* Molecular structure, molecular weight, and density at the desired temperature.

*Description:* This method is based on the Lorentz-Lorenz relation between the molar refraction $R_D$ and the refractive index, which can be written in the form

$$n = \sqrt{\frac{M + 2\left(\dfrac{\rho}{\text{gm}\cdot\text{cm}^{-3}}\right)R_D}{M - \left(\dfrac{\rho}{\text{gm}\cdot\text{cm}^{-3}}\right)R_D}} \tag{2-22}$$

where $n$ is refractive index at the same temperature as the density $\rho$. Wildman and Crippen developed a GC method for $R_D$ with the atomic contributions shown in Table 2-160 for each type of atom with its bonded neighbors.

***Example*** Calculate the refractive index of *m*-ethylphenol at 298.15 K. The various types of atoms corresponding to the descriptions in Table 2-160 are identified in the 2-D structural diagram shown here.



The molecular weight of *m*-ethylphenol is 122.16 kg/kmol, and its liquid density at 298.15 K is given in the DIPPR database as 1.00651 g/cm$^3$. The group contributions are summed up as shown in this table:

| Type | Description | Number | Value | Contribution |
|---|---|---|---|---|
| C1 | 1° & 2° aliphatic | 2 | 2.503 | 5.006 |
| C18 | aromatic | 4 | 3.350 | 13.40 |
| C21 | 4° aromatic –aliphatic C | 1 | 3.509 | 3.509 |
| C23 | 4° aromatic –O attached | 1 | 3.853 | 3.853 |
| O2 | alcohol | 1 | 0.8238 | 0.8238 |
| H1 | hydrocarbon | 9 | 1.057 | 9.513 |
| H2 | alcohol | 1 | 1.395 | 1.395 |
| | Group Sum | 19 | $R_D$ | 37.4998 |

**TABLE 2-160 Wildman-Crippen Contributions for Refractive Index[a]**

Table-specific nomenclature: e = N, O, P, S, F, Cl, Br, or I; ! = not (e.g., !e = not any of the e elements); c = aromatic carbon; n = aromatic nitrogen; o = aromatic oxygen; A = any nonhydrogen atom; a = aromatic, not necessarily carbon; bond types are single (—), double (═), triple (#), and aromatic (:)

| Type | Description | MR | Type | Description | MR |

[a]Wildman, S. A., and G. M. Crippen, *J. Chem. Inf. Comput. Sci.* **39** (1999): 868.

This value for $R_D$ is used in Eq. (2.22) to obtain

$$n = \sqrt{\frac{122.16 + 2(1.00651)(37.4998)}{122.16 - (1.00651)(37.4998)}} = 1.530$$

The predicted value differs by 0.3 percent from the experimental value of 1.535 given in the DIPPR database.

**Dielectric Constant** The dielectric constant is the ratio of the electric field strength in vacuum to that in the material for the same charge distribution. Equivalently, it is the ratio of the capacitance between two parallel charged plates when filled with the material to that of a vacuum with identical charges on the plates.

***Recommended Method*** Liu method.

*Reference:* Liu, J-P, W. V. Wilding, N. F. Giles, and R. L. Rowley, *J. Chem. Eng. Data* **55** (2010): 41–45.

*Classification:* QSPR.

*Expected uncertainty:* Generally less than 1 percent for nonpolar organic liquids and less than 20 percent for polar organic liquids.

*Applicability:* Organic liquids. Not valid if the predicted dielectric constant is greater than 50.

*Input data:* For hydrocarbons and nonpolar molecules, the dipole moment $\mu$, solubility parameter $\delta$, and refractive index $n$ are required. For polar and nonhydrocarbon molecules, the van der Waals area $A_{vdw}$ and number of oxygen-containing groups are additionally required.

*Description:* The general correlation for the dielectric constant $\varepsilon$ is

$$\ln \varepsilon = C_0 + C_1\left(\frac{\mu}{\mathrm{D}}\right) + C_2\left(\frac{A_{vdw}}{\mathrm{m}^2 \cdot \mathrm{kmol}^{-1}}\right)^{-1} + C_3\left(\frac{\delta}{\mathrm{J}^{1/2} \cdot \mathrm{m}^{-3/2}}\right) + C_4 n^2 + \sum_{i}^{\text{O Groups}} \frac{G_i}{k_i} \tag{2-23}$$

with the coefficients given by

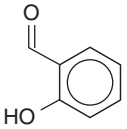
| Applicability | $C_0$ | $C_1$ | $C_2$ | $C_3$ | $C_4$ |
|---|---|---|---|---|---|
| Hydrocarbons and nonpolar | −0.1694 | 0.1283 | 0 | $2.8251 \times 10^{-5}$ | 0.2150 |
| | −0.3416 | 0.5239 | $4.072 \times 10^{8}$ | $7.408 \times 10^{-5}$ | −0.3248 |

The summation term shown in Eq. (2.23) is only for oxygen-containing groups in the molecule in which $G_i$ is the contribution shown below and $k_i$ ($k_i > 1$) is the number of occurrences of that group in the molecule.

| Group | Example | $G_i$ | Group | Example | $G_i$ |
|---|---|---|---|---|---|
| [S, N, P] = O | thionyl chloride | 0.2879 | –OH(na) | alcohol | 0.2230 |
| >C=O | ketone | 0.3615 | –OH(a) | phenol | 0.0990 |
| >C=O ring | 2-pyrrolidone | 0.0075 | –OH(C < 5)* | ethanol | 0.3348 |
| –COO– | ester | –0.0650 | –CHO | aldehyde | 0.1617 |
| –COOH | acid | –0.5900 | | | |

*Applied in addition to regular –OH group for molecules with fewer than 5 C atoms.

***Example*** Calculate the dielectric constant of salicylaldehyde at 303 K. The structure of salicylaldehyde is shown below with the two different oxygen-containing groups and their contributions that are to be used in Eq. (2.23).



| Group | $G_i$ | $k_i$ |
|---|---|---|
| —CHO | 0.1617 | 1 |
| —OH(a) | 0.0990 | 1 |

Values of the input properties for Eq. (2.23) obtained from the DIPPR database are $\mu = 3.08794$ D, $A_{vdw} = 8.43 \times 10^8$ m$^2$/kmol, $\delta = 21330$ J$^{1/2}$·m$^{-3/2}$, $n = 1.57017$. Equation (2.23) is then used to obtain the dielectric constant:

$$\ln \varepsilon = -0.3416 + (0.5239)(3.08794) + \frac{4.072}{8.43} + (7.408 \times 10^{-5})(21330) - (0.3248)(1.57017)^2 + 0.1617 + 0.0990$$

$$\ln \varepsilon = 2.799 \text{ and } \varepsilon = 16.43$$

A few reported experimental values are 13.9 at 293 K, 17.1 at 303 K, and 18.35 at 293.15 K.

## VAPOR PRESSURE

**Liquids** Vapor pressure is the equilibrium pressure at a given temperature of pure, coexisting liquid and vapor phases. The vapor pressure curve is a monotonic function of temperature from its minimum value (the triple point pressure) at the triple point temperature $T_t$, to its maximum value, $P_c$, at $T_c$.

Liquid vapor pressure data over a limited temperature range can be correlated with the Antoine equation [Antoine, C., *C.R.*, **107** (1888): 681, 836]

$$\ln \frac{P^*}{\text{Pa}} = A - \frac{B}{T/\text{K} + C} \tag{2-24}$$

Data from the triple point to the critical point can be correlated with either a modified form of the Wagner equation [Wagner, W., *A New Correlation Method for Thermodynamic Data Applied to the Vapor-Pressure Curve of Argon, Nitrogen, and Water,* J. T. R. Watson (trans. and ed.), IUPAC Thermodynamic Tables Project Centre, London, 1977; Ambrose, D., *J. Chem. Thermodyn.*, **18** (1986): 45; Ambrose, D., and N. B. Ghiassee, *J. Chem. Thermodyn.*, **19** (1987): 903, 911]

$$\ln P_r^* = \frac{a\tau + b\tau^{1.5} + c\tau^{2.5} + d\tau^5}{1 - \tau} \qquad \text{where } \tau \equiv 1 - T_r \tag{2-25}$$

or the Riedel equation [Riedel, L., *Chem. Ing. Tech.*, **26** (1954): 679]

$$\ln \frac{P^*}{\text{Pa}} = A + \frac{B}{T/\text{K}} + C \ln \frac{T}{\text{K}} + D\left(\frac{T}{\text{K}}\right)^E \tag{2-26}$$

In its original form, $E$ in Eq. (2-26) was assigned a value of 6, but other integer values of $E$ from 1 to 6 have been found to be more effective for different families of chemicals in representing the vapor pressure over the whole liquid range. With the best value of $E$, either the Riedel or the Wagner equation can be used to correlate most fluids over the whole liquid range, but a fifth term is used in the Wagner equation for alcohols [Poling, B. E., *Fluid Phase Equilib.,* **116** (1996): 102]:

$$\ln P_r^* = \frac{a\tau + b\tau^{1.5} + c\tau^{2.5} + d\tau^5 + e\tau^6}{1 - \tau} \qquad \text{(for alcohols)} \tag{2-27}$$

Correlation of experimental data within a few tenths of a percent over the entire fluid range can usually be obtained with either the Wagner or Riedel equations.

Two prediction methods are recommended for liquid vapor pressure. The first method is based on the Riedel equation; the second is a CS method. Both methods require $T_c$ and $P_c$ as input, but these can be estimated by the methods shown earlier if experimental values are unavailable.

***Recommended Method 1*** Riedel method.

*Reference:* Riedel, L., *Chem. Ing. Tech.*, **26** (1954): 679.

*Classification:* Empirical extension of theory and corresponding states.

*Expected uncertainty:* Varies strongly depending upon relative $T$, but 1 percent or less above $T_b$ is typical with uncertainties of 5 to 30 percent near the triple point.

*Applicability:* Most organic compounds.

*Input data:* $T_b$, $T_c$, $P_c$.

*Description:* Equation (2-26) in reduced form

$$\ln P_r = A + \frac{B}{T_r} + C \ln T_r + DT_r^6 \tag{2-28}$$

is used with the constants for this equation determined from the following set of relationships:

$$\psi = -35 + \frac{36}{T_{br}} + 42 \ln T_{br} - T_{br}^6 \qquad \alpha_c = \frac{3.758K\psi + \ln(P_c/1.01325 \text{ bar})}{K\psi - \ln T_{br}}$$

$$h = T_{br} \frac{\ln(P_c/1.01325 \text{ bar})}{1 - T_{br}} \qquad D = K(\alpha_c - 3.758)$$

(2-28a)

$$C = \alpha_c - 42D \qquad B = -36D \qquad A = 35D$$

Values of the constant $K$ [Vetere, A., *Ind. Eng. Chem. Res.*, **30** (1991): 2487] are as follows:

| Class | Value |
|---|---|
| Acids | $K = -0.120 + 0.025h$ |
| Alcohols | $K = 0.373 - 0.030h$ |
| All other organic compounds | $K = 0.0838$ |

***Example*** Estimate the vapor pressure of chlorobenzene at 50 K intervals from 300 to 600 K.

*Input information:* From the DIPPR 801 database, $T_b = 404.87$ K, $T_c = 632.35$ K, and $P_c = 45.1911$ bar.

*Auxiliary Quantities:*

$$K = 0.0838 \qquad T_{br} = 404.87/632.35 = 0.640$$

$$\psi = -35 + \frac{36}{0.640} + 42 \ln(0.640) - (0.640)^6 = 2.431$$

$$\alpha_c = \frac{(3.758)(0.0838)(2.431) + \ln(45.191/1.01325)}{(0.0838)(2.431) - \ln(0.640)} = 7.0248$$

$$D = (0.0838)(7.0248 - 3.758) = 0.2738 \qquad C = 7.0248 - (42)(0.2738) = -4.4729$$

$$B = -(36)(0.2738) = -9.8552 \qquad A = -(35)(0.2738) = 9.5814$$

*Calculation using Eq. (2-28) at each T (detailed calculation shown for T = 500 K):*

$$T_r = 500/632.35 = 0.7907$$

$$\ln P_r = 9.5814 - \frac{9.8552}{0.7907} - 4.4729 \ln 0.7907 + (0.2738)(0.7907)^6 = -1.7651$$

$$P_r = \exp(-1.7651) = 0.1712 \qquad P = P_r P_c = (0.1712)(45.1911 \text{ bar}) = 7.74 \text{ bar}$$

| $T$/K | $T_r$ | $\ln P_r$ | $P$/bar | $P_{\text{DIPPR}}$/bar | % Error |
|---|---|---|---|---|---|
| 300 | 0.4744 | −7.8532 | 0.0176 | 0.0175 | 0.3 |
| 350 | 0.5535 | −5.5704 | 0.172 | 0.172 | 0.1 |
| 400 | 0.6326 | −3.9323 | 0.886 | 0.880 | 0.6 |
| 450 | 0.7116 | −2.7101 | 3.01 | 2.98 | 0.9 |
| 500 | 0.7907 | −1.7651 | 7.74 | 7.67 | 0.9 |
| 550 | 0.8698 | −1.0067 | 16.51 | 16.39 | 0.8 |
| 600 | 0.9488 | −0.3705 | 31.20 | 31.11 | 0.3 |

***Recommended Method 2*** Ambrose-Walton method.

*References:* Ambrose, D., and J. Walton, *Pure & Appl. Chem.,* **61** (1989): 1395; Lee, B. I., and M. G. Kesler, *AIChE J.,* **21** (1975): 510.

*Classification:* Corresponding states.

*Expected uncertainty:* Varies strongly with relative $T$, but less than 1 percent is typical above $T_b$ if the acentric factor is known.

*Applicability:* Most organic compounds.

*Input data:* $T_b$, $T_c$, $P_c$, and $\omega$.

*Description:* The acentric factor is used to interpolate within the simple-fluid and deviation terms for $\ln P^*$. The $f^{(i)}$ terms have been obtained from correlations of the reference fluid vapor pressures with the Wagner vapor pressure equation

$$\ln P_r^* = f^{(0)} + \omega f^{(1)} + \omega^2 f^{(2)}$$

$$f^{(0)} = \frac{-5.97616\tau + 1.29874\tau^{1.5} - 0.60394\tau^{2.5} - 1.06841\tau^5}{1 - \tau}$$

$$f^{(1)} = \frac{-5.03365\tau + 1.11505\tau^{1.5} - 5.41217\tau^{2.5} - 7.46628\tau^5}{1 - \tau} \tag{2-29}$$

$$f^{(2)} = \frac{-0.64771\tau + 2.41539\tau^{1.5} - 4.26979\tau^{2.5} + 3.25259\tau^5}{1 - \tau}$$

where $\tau = 1 - T_r$.

***Example*** Repeat the calculation of the liquid vapor pressure of chlorobenzene at 50-K intervals from 300 to 600 K using the Ambrose-Walton method.

*Input information:* From the DIPPR 801 database, $T_c = 632.35$ K, $P_c = 45.1911$ bar, and $\omega = 0.249857$.

*Auxiliary quantities:*

$$T_r = 500/632.35 = 0.7907 \qquad \tau = 1 - 0.7907 = 0.2093$$

*Simple-fluid and deviation vapor pressure terms at each T (shown for T = 500 K):*

$$f^{(0)} = \frac{(-5.97616)(0.2093) + (1.29874)(0.2093)^{1.5} - (0.60394)(0.2093)^{2.5} - (1.06841)(0.2093)^{5}}{0.7907}$$
$$= -1.4405$$

$$f^{(1)} = \frac{(-5.03365)(0.2093) + (1.11505)(0.2093)^{1.5} - (5.41217)(0.2093)^{2.5} - (7.46628)(0.2093)^{5}}{0.7907}$$
$$= -1.3383$$

$$f^{(2)} = \frac{(-0.64771)(0.2093) + (2.41539)(0.2093)^{1.5} - (4.26979)(0.2093)^{2.5} + (3.25259)(0.2093)^{5}}{0.7907}$$
$$= 0.0145$$

*Calculation using Eq. (2-29):*

$$\ln P_r^* = -1.4405 + (0.249857)(-1.3383) + (0.249857)^2(0.0145) = -1.774$$

$$P^* = (45.1911 \text{ bar})[\exp(-1.774)] = 7.667 \text{ bar}$$

| $T$ | $\tau$ | $f^{(0)}$ | $f^{(1)}$ | $f^{(2)}$ | $\ln P^*_r$ | $P^*$/bar | $P^*_{\text{DIPPR}}$/bar | % Error |

**Solids** Below the triple point, the pressure at which the solid and vapor phases of a pure component are in equilibrium at any given temperature is the vapor pressure of the solid. It is a monotonic function of temperature with a maximum at the triple point. Solid vapor pressures can be correlated with the same equations used for liquids. Estimation of solid vapor pressure can be made from the integrated form of the Clausius-Clapeyron equation

$$\ln \frac{P^*}{P_t^*} = \frac{\Delta H_{\text{sub}}}{RT_t}\left(1 - \frac{T_t}{T}\right) \tag{2-30}$$

where $T_t$ = triple point temperature
$P_t^*$ = triple point pressure
$\Delta H_{\text{sub}}$ = enthalpy of sublimation

The liquid and solid vapor pressures are identical at the triple point. A good vapor pressure correlation that is valid at the triple point may be used to obtain the triple point pressure. Estimating solid vapor pressures by using Eq. (2-30) generally requires an estimation of $\Delta H_{\text{sub}}$, and so the illustrative example is combined with the example on enthalpy of sublimation in the section on latent enthalpy.

## THERMAL PROPERTIES

**Enthalpy of Formation** The standard enthalpy (heat) of formation is the enthalpy change upon formation of 1 mole of the compound in its standard state from its constituent elements in their standard states. Two different standard enthalpies of formation are commonly defined based on the chosen standard state. The standard enthalpy of formation $\Delta H_f^s$ uses the naturally occurring phase at 298.15 K and 1 bar as the standard state while the ideal gas enthalpy (heat) of formation $\Delta H_f^o$ uses the compound in the ideal gas state at 298.15 K and 1 bar as the standard state. In both cases, the standard state for the elements is their naturally occurring state of aggregation at 298.15 K and 1 atm. Sources for data include DIPPR, TRC, SWS, JANAF, and TDB. The Domalski-Hearing method is the most accurate general method for estimating either $\Delta H_f^s$ or $\Delta H_f^o$ if the appropriate GC values are available, but a CC method is also as accurate for estimating $\Delta H_f^o$ if an isodesmic reaction can be formulated and used. The Domalski-Hearing method also applies to entropies, and the entropy predictive equations are listed in this section for convenience because they are equivalent in form to the enthalpy equations. However, discussion and illustration of the estimation methods for entropy are delayed to the next subsection.

***Recommended Method*** Domalski-Hearing method.

*Reference:* Domalski, E. S., and E. D. Hearing, *J. Phys. Chem. Ref. Data*, **22** (1993): 805.

*Classification:* Group contributions.

*Expected uncertainty:* 3 percent.

*Applicability:* Organic compounds for which group contributions have been regressed.

*Input data:* Molecular structure.

*Description:* GC values from Table 2-161 are directly additive for both enthalpy of formation and absolute third-law entropies:

$$\frac{\Delta H_f^o}{\text{kJ/mol}} = \sum_{i=1}^{N} n_i (\Delta H_f^o)_i \qquad \frac{S^o}{\text{J}\cdot\text{mol}^{-1}\text{K}^{-1}} = \sum_{i=1}^{N} n_i (S^o)_i \tag{2-31}$$

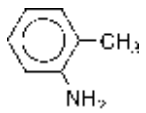
where $(\Delta H_f^o)_i$ = enthalpy of formation GC value and $(S^o)_i$ = entropy GC value, both obtained from Table 2-161.

Group values in Table 2-161 are defined by the central, nonhydrogen group and the atoms bonded to that group. Thus, C—(2H)(2C) represents a C atom to which 2 H and 2 C atoms are bonded. For example, propane ($CH_3$—$CH_2$—$CH_3$) is composed of three groups: two C—(3H)(C) and one C—(2H)(2C).

***Example*** Estimate the standard and ideal gas enthalpies of formation of *o*-toluidine.

*Input information:* Because the melting point (256.8 K) and boiling point (473.49 K) for *o*-toluidine bracket 298.15 K, the standard state phase at 298.15 K and 1 bar is liquid.

*Structure:*



*Group contributions:*

| Group | $n_i$ | $\Delta H_f^o$ gas | $\Delta H_f^o$ liq. | $S^o$ gas | $S^s$ liq. |
|---|---|---|---|---|---|
| Cb—(H)(2Cb) | 4 | 13.81 | 8.16 | 48.31 | 28.87 |
| Cb—(C)(2Cb) | 1 | 23.64 | 19.16 | −35.61 | −19.50 |
| Cb—(N)(2Cb) | 1 | −1.30 | 1.50 | −43.53 | −24.43 |
| C—(3H)(C) | 1 | −42.26 | −47.61 | 127.32 | 83.30 |
| N—(2H)(Cb) | 1 | 19.25 | −11.00 | 126.90 | 71.71 |
| | Total | 54.57 | −5.31 | 368.32 | 226.56 |

*Calculation from Eq. (2-31):*

$$\frac{\Delta H_f^o}{\text{kJ/mol}} = 54.57 \qquad \frac{\Delta H_f^s}{\text{kJ/mol}} = -5.31$$

$$\frac{S^o}{\text{J/(mol}\cdot\text{K)}} = 368.32 \qquad \frac{S^s}{\text{J/(mol}\cdot\text{K)}} = 226.56$$

The recommended DIPPR 801 standard enthalpies of formation are $\Delta H_f^o$ = 53.20 kJ/mol and $\Delta H_f^s$ = −4.72 kJ/mol. The estimated values are higher than the recommended values by 2.6 and 12.5 percent, respectively. The recommended DIPPR 801 standard entropies are $S^o$ = 355.8 J/(mol · K) and $S^s$ = 231.2 J/(mol · K). The estimated values differ from these by 3.5 and −2.0 percent, respectively.

***Recommended Method*** Isodesmic reaction.

*Reference:* Foresman, J. B., and A. Frisch, *Exploring Chemistry with Electronic Structure Methods*, 2d ed., Gaussian Inc., Pittsburgh, Pa., 1996.

*Classification:* Computational chemistry.

*Expected uncertainty:* 5 to 10 percent depending upon the level of theory and basis set size used.

*Applicability:* Compounds for which an isodesmic reaction can be formulated.

*Input data:* Experimental $\Delta H_f^o$ values for all *other* participants in the isodesmic reaction.

*Description:* While *ab initio* calculations of *absolute* enthalpies are not currently as accurate as GC methods, *relative* enthalpies of molecules calculated with the same level of theory and basis set can be very accurate, as in the case of isodesmic reactions. An isodesmic reaction is one in which the number and type of bonds are preserved during the reaction. For example, the reaction of acetaldehyde with ethane to form acetone and methane is

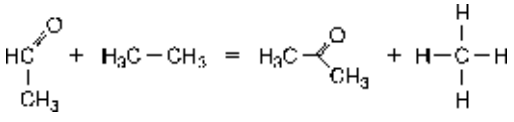


**TABLE 2-161 Domalski-Hearing* Group Contribution Values for Standard State Thermal Properties**

*Domalski, E. S., and E. D. Hearing, *J. Phys. Chem. Ref. Data*, **22** (1993): 805.

isodesmic with 12 single bonds and 1 double bond in both reactants and products. To use this method, one devises an isodesmic reaction involving the compound for which $\Delta H_f^o$ is to be determined with other compounds for which experimental $\Delta H_f^o$ values are available. *Ab initio* calculations are performed on all the participating compounds, all at the same level of theory and basis set size, to obtain the enthalpy for each at 298.15 K. The enthalpy of reaction is then calculated from

$$\Delta H_{rxn} = \sum \nu_i H_i \tag{2-32}$$

where $\nu_i$ = stoichiometric coefficient of $i$ (+ for products, − for reactants). The enthalpy of reaction is also related to $\Delta H_f^o$ by

$$\Delta H_{rxn} = \sum \nu_i (\Delta H_f^o)_i \tag{2-33}$$

With experimental values available for all $\Delta H_f^o$ except the desired compound, its value can be back-calculated from Eq. (2-33).

***Example*** Estimate the standard ideal gas enthalpy of formation of acetaldehyde.

*Input information:* The isodesmic reaction shown above will be used. The recommended $\Delta H_f^o$ values from DIPPR 801 for the other three compounds are as follows:

| Acetone | Methane | Ethane |
|---|---|---|
| −215.70 kJ/mol | −74.52 kJ/mol | −83.82 kJ/mol |

*Ab initio calculations of enthalpy:* With structures optimized using HF/6-31G(d) model chemistry and energies calculated with B3LYP/6-311+G(3df,2p), the following enthalpies are obtained (including the zero-point energy):

| Acetone | Methane | Ethane | Acetaldehyde |
|---|---|---|---|
| $-5.071 \times 10^5$ kJ/mol | $-1.063 \times 10^5$ kJ/mol | $-2.095 \times 10^5$ kJ/mol | $-4.039 \times 10^5$ kJ/mol |

*Calculation using Eq. (2-32):*

$$\Delta H_{rxn} = (-1.063 - 5.071 + 2.095 + 4.039) \times 10^5 \text{ kJ/mol} = -41.67 \text{ kJ/mol}$$

*Calculation using Eq. (2-33):*

$$\Delta H^o_{f,\text{acetaldehyde}} = \Delta H^o_{f,\text{acetone}} + \Delta H^o_{f,\text{methane}} - \Delta H^o_{f,\text{ethane}} - \Delta H_{rxn}$$

$$\Delta H^o_{f,\text{acetaldehyde}} = (-215.70 - 74.52 + 83.82 + 41.67)\frac{\text{kJ}}{\text{mol}} = -164.73\frac{\text{kJ}}{\text{mol}}$$

The estimated value is 1.0 percent above the DIPPR 801 recommended value of −166.40 kJ/mol.

**Entropy** Absolute or third-law entropies (relative to a perfectly ordered crystal at 0 K) of a compound in its standard state $S^s$ or of an ideal gas $S^o$ at 298.15 K and 1 bar can be found in various literature sources (DIPPR, JANAF, TRC, SWS, and TDB). Very good estimates for $S^s$ or $S^o$ can be obtained by using the Domalski-Hearing method. Excellent $S^o$ values can also be obtained from statistical mechanics by using experimental vibrational frequencies or values of the frequencies generated from computational chemistry.

The standard $\Delta S_f^s$ and ideal gas $\Delta S_f^o$ entropies of formation at 298.15 K and 1 bar are related to the standard entropies by

$$\Delta S_f^s = S^s_{\text{compound}} - \sum_{i=1}^{n_A} \nu_i S^s_{\text{element},i} \qquad \Delta S_f^o = S^o_{\text{compound}} - \sum_{i=1}^{n_A} \nu_i S^s_{\text{element},i} \tag{2-34}$$

where $S^s_{\text{element},i}$ is the absolute entropy of element $i$ in its standard state at 298.15 K and 1 bar.

***Recommended Method*** Domalski-Hearing method.

*Reference:* Domalski, E. S., and E. D. Hearing, *J. Phys. Chem. Ref. Data*, **22** (1993): 805.

*Classification:* Group contributions.

*Expected uncertainty:* 3 percent.

*Applicability:* Organic compounds for which group contributions have been regressed.

*Input data:* Molecular structure.

*Description:* See description given under Enthalpy of Formation above.

***Example*** Estimate the standard and ideal gas entropies of formation of *o*-toluidine.

*Standard state entropies:* Estimation of $S^s$ and $S^o$ using the Domalski-Hearing method was illustrated above in the Enthalpy of Formation section. The standard entropies of formation can be obtained from the values determined in that example.

*Formula:* $C_7H_9N$. The standard entropies of the elements from the DIPPR 801 database are as follows:

| Compound | $N_2$ | $H_2$ | C, graphite |
|---|---|---|---|
| $\nu_i$ | 1/2 | 9/2 | 7 |
| $S_i^s$/[J(kmol·K)] | $1.9151 \times 10^5$ | $1.3057 \times 10^5$ | 5740 |

Entropies of formation can be calculated from these values by using Eq. (2-34):

$$\Delta S_f^s = \left[2.2656 - \left(\frac{1}{2}\right)(1.9151) - \left(\frac{9}{2}\right)(1.3057) - (7)(0.0574)\right]\frac{10^5\,\text{J}}{\text{kmol}\cdot\text{K}}$$

$$= -4.969\cdot 10^5 \frac{\text{J}}{\text{kmol}\cdot\text{K}}$$

$$\Delta S_f^o = \left[3.6832 - \left(\frac{1}{2}\right)(1.9151) - \left(\frac{9}{2}\right)(1.3057) - (7)(0.0574)\right]\frac{10^5\,\text{J}}{\text{kmol}\cdot\text{K}}$$

$$= -3.552\cdot 10^5 \frac{\text{J}}{\text{kmol}\cdot\text{K}}$$

***Recommended Method*** Statistical mechanics.

*Classification:* Theory and computational chemistry.

*Expected uncertainty:* 0.2 percent if vibrational frequencies (or their characteristic temperatures) are experimentally available; uncertainty depends upon model chemistry if frequencies are determined from computational chemistry, but generally within about 5 percent.

*Applicability:* Ideal gases.

*Input data:* $M$; $\sigma$ (external symmetry number); characteristic rotational temperature(s) ($\Theta_A$ for linear molecules; $\Theta_A$, $\Theta_B$, and $\Theta_C$ for nonlinear molecules); and $3n_A - 6 + \delta$ characteristic vibrational temperatures $\Theta_j$.

*Description:* For harmonic frequencies, the rigorous temperature dependence of $S^o$ is given by

$$\frac{S^o}{R} = \frac{3}{2}\ln\left(6175\frac{M}{\text{kg/kmol}}\right) + \frac{S_r}{R} + \sum_{j=1}^{3n_A-6+\delta}\left[\left(\frac{\Theta_j}{T}\right)(e^{\Theta_j/T}-1)^{-1} - \ln\left(1-e^{-\Theta_j/T}\right)\right] \tag{2-35}$$

where $\delta = \begin{cases} 0 & \text{nonlinear} \\ 1 & \text{linear} \end{cases}$

and $\dfrac{S_r}{R} = \begin{cases} \ln\left[\dfrac{1}{\sigma}\left(\dfrac{\pi T^3 e^3}{\Theta_A\Theta_B\Theta_C}\right)^{1/2}\right] & \text{nonlinear} \\ \ln\left[\left(\dfrac{Te}{\sigma\Theta_A}\right)\right] & \text{linear} \end{cases}$

***Example*** Calculate $S^o$ for ammonia.

*Structure:* $NH_3$.

*Input data:* $M$ = 17 kg/kmol. McQuarrie [McQuarrie, D. A., *Statistical Mechanics*, Harper & Row, New York, 1976] gives the following $3n_A - 6 + \delta = 12 - 6 + 0 = 6$ characteristic vibrational temperatures (in K): 1360, 2330, 2330, 4800, 4880, 4880. The characteristic rotational temperatures given by McQuarrie are $\Theta_A$ = 13.6 K, $\Theta_B$ = 13.6 K, and $\Theta_C$ = 8.92 K. For $NH_3$, $\sigma$ = 3.

*Vibrational contribution:* The table below shows a spreadsheet calculation of the vibrational terms inside the summation sign in Eq. (2-35).

| $\Theta_j$/K | $\Theta_j$/(298.15 K) | $S_{\text{vib}}$ |
|---|---|---|
| 1207.91 | 4.051 | 0.08929 |
| 1850.16 | 6.205 | 0.01457 |
| 1850.16 | 6.205 | 0.01457 |
| 3688.19 | 12.370 | 0.00006 |
| 3821.36 | 12.817 | 0.00004 |
| 3821.36 | 12.817 | 0.00004 |
| | Sum | 0.1186 |

*Rotational contribution:*

$$\frac{S_r}{R} = \ln\left\{\frac{1}{3}\cdot\left[\frac{(298.15\,\text{K})^3\pi e^3}{(13.6\,\text{K})(13.6\,\text{K})(8.92\,\text{K})}\right]^{1/2}\right\} = 5.81593$$

*Calculation using Eq. (2-35):*

$$\frac{S^o_{298}}{R} = \frac{3}{2}\ln(6175.17) + 5.81593 + 0.1186 = 23.277$$

$$S^o_{298} = 1.935\times 10^5 \frac{\text{J}}{\text{kmol}\cdot\text{K}}$$

The calculated value differs from the DIPPR 801 recommended value of $1.927 \times 10^5$ J/(kmol·K) by 0.5 percent.

**Gibbs Energy of Formation** The standard Gibbs energy of formation is the Gibbs energy change upon formation of 1 mole of the compound in its standard state from its constituent elements in their standard states. The standard Gibbs energy of formation $\Delta G_f^s$ uses the naturally occurring phase at 298.15 K and 1 bar as the standard state, while the ideal gas Gibbs energy of formation $\Delta G_f^o$ uses the compound in the ideal gas state at 298.15 K and 1 bar as the standard state. In both cases, the standard state for the elements is their naturally occurring state of aggregation at 298.15 K and 1 bar. Sources for data include DIPPR, TRC, JANAF, and TDB. The Gibbs energies of formation are related to the corresponding enthalpies and entropies of formation by

$$\Delta G_f^o = \Delta H_f^o - T\Delta S_f^o \qquad \text{and} \qquad \Delta G_f^s = \Delta H_f^s - T\Delta S_f^s \tag{2-36}$$

and predicted values of $\Delta G_f^s$ and $\Delta G_f^o$ are obtained from Eq. (2-36) by estimating the enthalpies and entropies of formation as shown above.

## LATENT ENTHALPY

**Enthalpy of Vaporization** The enthalpy (heat) of vaporization $\Delta H_v$ is the difference between the molar enthalpies of the saturated vapor and saturated liquid at a temperature between the triple point and critical point (at the corresponding vapor pressure). Variable $\Delta H_v$ is related to the vapor pressure $P^*$ by the thermodynamically exact Clapeyron equation

$$\Delta H_v = -R\,\Delta Z_v \frac{d\ln P^*}{d(1/T)} = RT^2\Delta Z_v\frac{d\ln P^*}{dT} \tag{2-37}$$

where $\Delta Z_v = Z_G - Z_L$, $Z_G = Z$ of saturated vapor, and $Z_L = Z$ of saturated liquid. Experimental heats of vaporization can be effectively correlated with

$$\Delta H_v = A(1-T_r)^{B+CT_r+DT_r^2+ET_r^3} \tag{2-38}$$

A simple method for obtaining $\Delta H_v$ at one temperature from a known value at a reference temperature, say at the normal boiling point, is to truncate Eq. (2-38) after the $B$ term, set $B$ = 0.38, and take a ratio of the $\Delta H_v$ values at the two conditions to give the Watson [Thek, R. E., and L. I. Stiel, *AIChE J.*, **12** (1966): 599; **13** (1967): 626] correlation

$$\Delta H_v = \Delta H_{v,\,\text{ref}}\left(\frac{1-T_r}{1-T_{r,\,\text{ref}}}\right)^{0.38} \tag{2-39}$$

If an accurate correlation for $P^*$ and accurate values for $Z_G$ and $Z_L$ are available, Eq. (2-37) is the preferred method for obtaining enthalpies of vaporization. Otherwise, the CS methods shown below should be used.

***Recommended Method 1*** Vapor pressure correlation.

*Classification:* Extension of theory.

*Expected uncertainty:* The uncertainty varies significantly with temperature and with the quality and temperature range of the vapor pressure data used in the correlation.

*Applicability:* Organic compounds for which group contributions have been regressed.

*Input data:* Correlations for $P^*$, $Z_G$, and $Z_L$.

*Description:* An expression for $\Delta H_v$ can be obtained from Eq. (2-37) by using an appropriate vapor pressure correlation. If one differentiates the Riedel vapor pressure correlation, Eq. (2-26), in accordance with Eq. (2-37), one obtains the heat of vaporization as

$$\Delta H_v = R\,\Delta Z_v\,(-B + CT + DET^{E+1}) \tag{2-40}$$

The $Z_G$ and $Z_L$ values can be evaluated using the methods given in the section on densities below.

***Example*** Calculate $\Delta H_v$ for anisole at 452 K.

*Input data:* The vapor pressure coefficients in the DIPPR 801 database for Eq. (2-26) are

$$A = 128.06 \qquad B = -9307.7 \qquad C = -16.693 \qquad D = 0.014919 \qquad E = 1$$

The vapor pressure at 452 K is therefore

$$\ln\left(\frac{P^*}{\text{Pa}}\right) = 128.06 - \frac{9307.7}{452} - 16.693\ln(452) + 0.014919\,(452)^1 = 12.155$$

$$P^* = \exp\,(12.155)\cdot\text{Pa} = 1.901\times10^5\ \text{Pa}$$

*Determine $\Delta Z$:* Required data from the DIPPR 801 database for this calculation are $T_c$ = 645.6 K, $P_c$ = 4.25 MPa, and $\omega$ = 0.35017. These values are used to determine the reduced conditions,

$$T_r = \frac{452}{645.6} = 0.7 \qquad P_r = \frac{0.1901}{4.25} = 0.045$$

and the values of $Z_G$ and $Z_L$ from the Lee-Kesler corresponding states method as discussed in the section on density. Interpolation of the $P_r$ values in Tables 2-169 and 2-170 at a $T_r$ of 0.7 gives

$$Z_G^{(0)} = 0.9904 + \frac{0.045-0.010}{0.050-0.010}(0.9504 - 0.9904) = 0.9554$$

$$Z_G^{(1)} = -0.0064 + \frac{0.045-0.010}{0.050-0.010}(-0.0507 + 0.0064) = -0.0452$$

$$Z_G = Z_G^{(0)} + \omega Z_G^{(1)} = 0.9554 + (0.35017)(-0.0452) = 0.94$$

At this low pressure, $Z_L$ is very small compared to $Z_G$ and may be neglected; so

$$\Delta Z_V = Z_G - Z_L = 0.94$$

*Calculation using Eq. (2-40):*

$$\Delta H_v = \left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(0.94)[9307.7 - (16.693)(452) + (0.014919)(1)(452)^2]$$

$$= 37.59\frac{\text{kJ}}{\text{mol}\cdot\text{K}}$$

This value is 0.2 percent higher than the value of 37.51 kJ/(mol · K) obtained from the DIPPR 801 database.

***Recommended Method 2*** Corresponding states correlation.

*Reference:* [PGL5], p. 7.18.

*Classification:* Corresponding states.

*Expected uncertainty:* Less than about 6 percent.

*Applicability:* Organic compounds.

*Input data:* $T_c$, $P_c$, and $\omega$.

*Description:* The following correlation is used:

$$\frac{\Delta H_v}{RT_c} = 7.08\tau^{0.354} + 10.95\omega\tau^{0.456} \qquad \text{where } \tau = 1 - T_r \tag{2-41}$$

***Example*** Repeat the above calculation for anisole's $\Delta H_v$ at 452 K.

*Input data:* $T_c$ = 645.6 K, $P_c$ = 4.25 MPa, and $\omega$ = 0.35017.

*Auxiliary quantities:* From the previous example, the reduced temperature variables are

$$T_r = 0.7 \qquad \tau = 1 - 0.7 = 0.3$$

*Calculation using Eq. (2-41):*

$$\frac{\Delta H_v}{RT_c} = 7.08(0.3)^{0.354} + 10.95\,(0.35017)(0.3)^{0.456} = 6.838$$

$$\Delta H_v = (6.838)\left(8.314\frac{\text{J}}{\text{mol}\cdot\text{K}}\right)(645.6\ \text{K}) = 36.70\frac{\text{kJ}}{\text{mol}\cdot\text{K}}$$

This value is 2.2 percent below the DIPPR 801 recommended value of 37.51 kJ/(mol · K).

**Enthalpy of Fusion** The enthalpy (heat) of fusion $\Delta H_{\text{fus}}$ is the difference between the molar enthalpies of the equilibrium liquid and solid at the melting temperature and 1.0 atm pressure. There is no generally applicable, high-accuracy estimation method for $\Delta H_{\text{fus}}$, but the GC method of Chickos can be used to obtain approximate results if the melting temperature is known.

***Recommended Method*** Chickos method.

*Reference:* Chickos, J. S., C. M. Braton, D. G. Hesse, and J. R. Liebman, *J. Org. Chem.*, **56** (1991): 927.

*Classification:* QSPR and group contributions.

*Expected uncertainty:* Considerable variation but generally less than 50 percent.

*Applicability:* Only valid at the melting temperature. The method is based on the $\Delta S_{\text{fus}}$ between a solid at 0 K and the liquid at the $T_m$ so no solid-solid transitions are taken into account. Values of $\Delta H_{\text{fus}}$ will be overestimated if there are solid-solid transitions for the actual material.

*Input data:* $T_m$ and molecular structure.

*Description:*

$$\frac{\Delta H_{\text{fus}}}{\text{J/mol}} = \frac{\Delta S_{\text{fus}}}{\text{J/(mol}\cdot\text{K)}}\left(\frac{T_m}{\text{K}}\right) = (T_m/\text{K})\,(a+b) \tag{2-42}$$

$$a = \begin{cases} 0 & \text{no nonaromatic rings} \\ 35.19N_R + 4.289(N_{CR} - 3N_R) & \text{nonaromatic rings} \end{cases} \tag{2-43}$$

$$b = \sum_{i=1}^{ng} Ng_i\Delta s_i + \sum_{j=1}^{ns} Ns_j Cs_j \Delta s_j + \sum_{k=1}^{nf} Nf_k Ct_k\ \Delta s_k \tag{2-44}$$

where $Ng_i$ = number of C—H groups of type $i$ bonded to other carbon atoms
$n_g$ = number of different nonring or aromatic C—H groups bonded to other carbon atoms
$Ns_j$ = number of C—H groups of type $j$ bonded to at least one functional group or atom
$n_s$ = number of different nonring or aromatic C—H groups bonded to at least one functional group or atom
$Nf_k$ = number of functional groups of type $k$
$n_f$ = number of different functional groups or atoms
$t$ = total number of functional groups or atoms with the exception that F atoms count as one regardless of number of occurrences
$Cs_j$ = value from Table 2-162 for C—H group $j$ bonded to at least one functional group or atom
$Ct_k$ = value from Table 2-163 for functional group $k$
$N_R$ = number of nonaromatic rings
$N_{CR}$ = number of —$CH_2$— groups in nonaromatic ring(s) required to form cyclic paraffin of same ring size(s)
$\Delta s_i$ = contribution from Table 2-162 for group $i$
$\Delta s_k$ = contribution from Table 2-163 for group $k$

Note that nonaromatic ring —$CH_2$ groups are accounted for in the $a$ term and are *not* included in the $b$ term.

***Example*** Calculate $\Delta H_{\text{fus}}$ at the melting point for (*a*) benzothiophene, (*b*) furfuryl alcohol, and (*c*) *cis*-crotonaldehyde.

*Structures:*

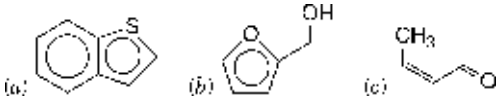

**TABLE 2-162 Cs (C—H) Group Values for Chickos Estimation* of $\Delta H_{fus}$**

| Group | Description | *Cs* | $\Delta s$ | Group | Description | *Cs* | $\Delta s$ |

$T_m = 258.52$ K from DIPPR 801 database

$\Delta H_{fus} = (T_m/\text{K})(a + b)$ J/mol = (258.52)(43.77 + 3.51) J/mol = 12.22 kJ/mol

This value is 7 percent lower than the DIPPR 801 recommended value of 13.13 kJ/mol.

(*c*) $t = 1$ $N_R = 0$ $a = 0$

| Group | Description | *N* | *C* | $\Delta s$ | Total |
|---|---|---|---|---|---|
| —$CH_3$ | nonring (*Ng* type) | 1 | 1 | 18.33 | 18.33 |
| =CH— | nonring (*Ng* type) | 1 | 1 | 4.85 | 4.85 |
| =CH— | nonring (*Ns* type) | 1 | 3.23 | 4.85 | 15.67 |
| —CHO | aldehyde | 1 | 1 | 19.66 | 19.66 |
| | | | | Total | 58.51 |

$T_m = 158.38$ K from DIPPR 801 database

$\Delta H_{fus} = (T_m/\text{K})(a + b)$ J/mol = (158.38)(0 + 58.51) J/mol = 9.27 kJ/mol

This value is 5 percent higher than the DIPPR 801 recommended value of 8.86 kJ/mol.

**Enthalpy of Sublimation** The enthalpy (heat) of sublimation $\Delta H_{sub}$ is the difference between the molar enthalpies of the equilibrium vapor and solid along the sublimation curve below the triple point. The effects of pressure on $\Delta H_{sub}$ and melting temperature are very small so that $T_t$ and the normal melting point are nearly equal and

$$\Delta H_{sub}(T_t) = \Delta H_v(T_t) + \Delta H_{fus}(T_t) \tag{2-45}$$

Equation (2-45) can be used to estimate $\Delta H_{sub}$ at the triple point if $\Delta H_v$ is accurately known at $T_t$. Because $\Delta H_v$ is usually obtained from Eq. (2-37), $\Delta H_v(T)$ correlations may be less accurate near $T_t$ where $P^*(T_t)$ is very small and difficult to measure. In this case, it is better to estimate $\Delta H_{sub}$ directly by using the following recommended method. $\Delta H_{sub}$ is only a weak function of temperature and can generally be treated as a constant from the triple point temperature down to the first solid-solid phase transition.

***Recommended Method*** Goodman method.

*Reference:* Goodman, B. T., W. V. Wilding, J. L. Oscarson, and R. L. Rowley, *Int. J. Thermophys.* **25** (2004): 337.

*Classification:* QSPR and group contributions.

*Expected uncertainty:* 6 percent.

*Applicability:* Organic compounds for which group contributions have been regressed.

*Input data:* Molecular structure and radius of gyration $R_G$.

*Description:*

$$\frac{\Delta H_{sub}(T_t)}{R\,\text{K}} = 698.04 + 3.83798 \times 10^{12}\left(\frac{R_G}{\text{m}}\right) + \sum_{i=1}^{N} n_i a_i + \sum_{i=1}^{N} n_i^2 \beta_i + \sum_{i=1}^{N} \frac{n_i}{n_x} f_i \tag{2-46}$$

where $a_i$ = GC values from Table 2-164

$\beta_i$ = nonlinear corrections for >$CH_2$ and Ar—CH = groups

$f_i$ = halogen corrections

$n_x$ = total number of all halogen and hydrogen atoms attached to C and Si atoms

***Example*** Calculate $\Delta H_{sub}$ and the solid vapor pressure for 1,2,3-trichlorobenzene at 301.15 K.

*Structure:*

*Calculation using Eq. (2-46):*

$$\frac{\Delta H_{sub}(T_t)}{R\,\mathrm{K}} = 698.04 + (3.838\times10^{12})(4.455\times10^{-10}) + 6657.05 + (3^2)(-2.21614) + \left(\frac{3}{6}\right)(-1543.66)$$

$$\Delta H_{sub}(T_t) = (8273\ \mathrm{K})\left(0.008314\frac{\mathrm{kJ}}{\mathrm{mol\cdot K}}\right) = 68.78\frac{\mathrm{kJ}}{\mathrm{mol}}$$

The estimated value is 5.6 percent above the DIPPR 801 recommended value of 65.11 kJ/mol.

*Estimate the solid vapor pressure at 301.15 K:* The solid vapor pressure can be calculated from Eq. (2-30) by using the estimated $\Delta H_{sub}$ and one additional solid vapor pressure point. In this example the triple point temperature and vapor pressure ($T_t$ = 325.65 K; $P_t^*$ = 182.957 Pa) from the DIPPR 801 database are used in Eq. (2-30):

$$\ln\frac{P^*}{182.957\ \mathrm{Pa}} = \frac{68.78\ \mathrm{kJ/mol}}{[0.008314\ \mathrm{kJ/(mol\cdot K)}](325.65\ \mathrm{K})}\left(1-\frac{325.65}{301.15}\right) = -2.067$$

$$P^* = (182.957\ \mathrm{Pa})\,[\exp(-2.067)] = 23.16\ \mathrm{Pa}$$

The estimated value is 0.3 percent above the DIPPR 801 recommended value of 23.09 Pa.

## HEAT CAPACITY

The isobaric heat capacity $C_P$ is defined as the energy required to change the temperature of a unit mass (specific heat) or mole (molar heat capacity) of the material by one degree at constant pressure. Typical units are J/(kg·K).

**Gases** The isobaric heat capacity of a gas is related rigorously to the ideal gas value $C_P^o$ by

$$C_P = C_P^o - T\int_0^P \left(\frac{\partial^2 V}{\partial T^2}\right)_P dP \tag{2-47}$$

The second term, giving the deviation of the real fluid heat capacity from the ideal gas value, can be neglected at low to moderate pressures, or it can be calculated directly from an appropriate EoS.

Ideal gas heat capacities are available from several sources (DIPPR, JANAF, TRC, and SWS). Two common correlating equations for $C_P^o$ are the Aly-Lee equation [Aly, F. A., and L. L. Lee, *Fluid Phase Equilib.*, **6** (1981): 169]

$$C_P^o = A_0 + A_1\left[\frac{A_2/T}{\sinh(A_2/T)}\right]^2 + A_3\left[\frac{A_4/T}{\cosh(A_4/T)}\right]^2 \tag{2-48}$$

and a polynomial form (generally fourth-order)

$$C_P^o = \sum_{i=0}^{4} A_i T^i \tag{2-49}$$

Ideal gas heat capacities may also be estimated from several techniques, of which two of the most accurate and commonly used are recommended here.

***Recommended Method 1*** Statistical mechanics.

*Reference:* Rowley, R. L., *Statistical Mechanics for Thermophysical Property Calculations,* Prentice-Hall, Englewood Cliffs, N.J., 1994.

*Classification:* Theory and computational chemistry.

*Expected uncertainty:* 0.2 percent if vibrational frequencies (or their characteristic temperatures) are experimentally available; accuracy depends upon model chemistry if frequencies are determined from computational chemistry, but generally within 3 percent.

*Applicability:* Ideal gases.

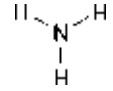
*Input data:* $3n_A - 6 + \delta$ vibrational frequencies $\nu_j$, or the corresponding characteristic vibrational temperatures $\Theta_j$. The two are related by

$$\Theta_j = h\nu_j/k \tag{2-50}$$

*Description:* For harmonic frequencies, the rigorous temperature dependence of $C_P^o$ is given by

$$\frac{C_P^o}{R} = \frac{8-\delta}{2} + \sum_{j=1}^{3n_A-6+\delta}\left(\frac{\Theta_j}{T}\right)^2\left[\frac{e^{\Theta_j/T}}{(e^{\Theta_j/T}-1)^2}\right] \qquad \delta = \begin{cases}0 & \text{nonlinear}\\ 1 & \text{linear}\end{cases} \tag{2-51}$$

***Example*** Calculate the ideal gas heat capacity of ammonia at 300 K.
*Structure:*



*Input data:* McQuarrie (McQuarrie, D. A., *Statistical Mechanics*, Harper & Row, New York, 1976) gives the following $3n_A - 6 + \delta = 12 - 6 + 0 = 6$ characteristic vibrational temperatures (in K): 1360, 2330, 2330, 4800, 4880, and 4880. Alternatively, a computational chemistry package gives the following *scaled* frequencies for HF/6-31G+ model chemistry ($10^{13}$ Hz): 3.24, 4.97, 4.97, 9.90, 10.26, and 10.26.

*Calculation:* The table on the left uses the experimental Θ values to determine the individual terms in the summation of Eq. (2-51). The table on the right uses the scaled frequencies from computational chemistry software and Eq. (2-50) to obtain Θ values and the individual terms in Eq. (2-51).

| Experimental frequencies | | | HF/6-31G+ scaled frequencies* | | | |
|---|---|---|---|---|---|---|
| Θ/K | Θ/(300 K) | Term | $\nu_{scaled}/10^{13}$ Hz | Θ/K | Θ/(300 K) | Term |
| 1360 | 4.533 | 0.2256 | 3.24 | 1555.0 | 5.183 | 0.1524 |
| 2330 | 7.767 | 0.0256 | 4.97 | 2385.3 | 7.951 | 0.0223 |
| 2330 | 7.767 | 0.0256 | 4.97 | 2385.3 | 7.951 | 0.0223 |
| 4800 | 16.000 | 0.0000 | 9.90 | 4751.4 | 15.838 | 0.0000 |
| 4880 | 16.267 | 0.0000 | 10.26 | 4924.2 | 16.414 | 0.0000 |
| 4880 | 16.267 | 0.0000 | 10.26 | 4924.2 | 16.414 | 0.0000 |
| | Sum: | 0.2768 | | | Sum: | 0.1970 |

*Empirical scaling factors have been developed for each model chemistry to help correct theoretical frequencies for anharmonic effects [Scott, A. P., and L. Radom, *J. Phys. Chem.*, **100** (1996): 16502].

*From experimental frequencies:*

$$C_p^o = \left(\frac{8}{2} + 0.2768\right) R = (4.2768)\left(8.3143 \frac{\text{J}}{\text{mol}\cdot\text{K}}\right) = 35.56 \frac{\text{J}}{\text{mol}\cdot\text{K}}$$

*From computational chemistry frequencies:*

$$C_p^o = \left(\frac{8}{2} + 0.197\right) R = (4.197)\left(8.3143 \frac{\text{J}}{\text{mol}\cdot\text{K}}\right) = 34.90 \frac{\text{J}}{\text{mol}\cdot\text{K}}$$

The value calculated from experimental frequencies is 0.1 percent lower than the DIPPR 801 recommended value of 35.61 J/(mol·K); the value calculated from frequencies generated from computational chemistry software is 2.0 percent lower than the DIPPR 801 value.

***Recommended Method 2*** Benson method as implemented in CHETAH program.

*References:* Benson, S. W., et al., *Chem. Rev.*, **69** (1969): 279; CHETAH Version 8.0: The ASTM Computer Program for Chemical Thermodynamic and Energy Release Evaluation (NIST Special Database 16).

*Classification:* Group contributions.

*Expected uncertainty:* 4 percent.

*Applicability:* Ideal gases of organic compounds.

*Input data:* Table 2-165 group values at the seven specified temperatures.

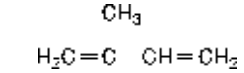
*Description:* Groups are summed at each individual temperature:

$$C_P^o = \sum_{i=1}^{N} n_i \cdot (C_p^o)_i \tag{2-52}$$

where $n_i$ = number of occurrences of group $i$ and $(C_p^o)_i$ = individual group contribution. Either Eq. (2-48) or Eq. (2-49) can be used to interpolate between the discrete temperatures.

***Example*** Calculate the ideal gas heat capacity of isoprene (2-methyl-1,3-butadiene) at 400 K.

*Structure:*



*Group identification and values:*

| Group | No. | Value, J/(mol·K) | Contribution, J/(mol·K) |
|---|---|---|---|
| $=CH_2$ | 2 | 26.62 | 53.24 |
| =C—(2C) | 1 | 19.3 | 19.3 |
| $—CH_3—(=C)$ | 1 | 32.82 | 32.82 |
| =CH—(C) | 1 | 21.05 | 21.05 |
| | | | Total 126.41 |

The value of 126.4 J/(mol·K) is 3.1 percent below the DIPPR 801 recommended value of 130.4 J/(mol·K).

**Liquids** Liquid isobaric heat capacity increases with increasing temperature, although a minimum occurs near the triple point for many compounds. Usually liquid heat capacity is correlated as a function of temperature with a polynomial equation; a third-order polynomial is usually adequate.

Estimation of liquid heat capacity can be done by using a number of methods [Ruzicka, V., and E. S. Domalski, *J. Phys. Chem. Ref. Data*, **22** (1993): 597, 619; Chueh, C. F., and A. C. Swanson, *Chem. Eng. Prog.*, **69**, 7 (1973): 83; Lee, B. I., and M. G. Kesler, *AIChE J.*, **21** (1975): 510; Tarakad, R. R., and R. P. Danner, *AIChE J.*, **23** (1977): 944] and thermodynamic differentiation. The Ruzicka-Domalski method is generally accurate at low temperature, but the cubic behavior can overestimate the temperature rise at higher temperatures. The Lee-Kesler method is accurate for nonpolar and slightly polar fluids, but has less accuracy for strongly polar or associating fluids.

***Recommended Method 1*** Ruzicka-Domalski.

*References:* Ruzicka, V., and E. S. Domalski, *J. Phys. Chem. Ref. Data*, **22** (1993): 597, 619.

*Classification:* Group contributions.

*Expected uncertainty:* 4 percent.

*Applicability:* Organic compounds for which group values are available.

*Input data:* Molecular structure and Table 2-166 values.

*Description:* Groups are summed to find the temperature coefficients for a cubic polynomial correlation:

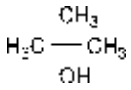
$$\frac{C_p}{R} = A + B\left(\frac{T}{100\ \text{K}}\right) + D\left(\frac{T}{100\ \text{K}}\right)^2 \tag{2-53}$$

$$A = \sum_{i=1}^{N} n_i a_i \qquad B = \sum_{i=1}^{N} n_i b_i \qquad D = \sum_{i=1}^{N} n_i d_i \tag{2-54}$$

where $n_i$ = number of occurrences of group $i$ and $a_i$, $b_i$, $d_i$ = individual group contributions.

***Example*** Estimate the liquid heat capacity for 2-methyl-2-propanol at 340 K.

*Structure:*



*Group contributions:*

| Group | $n_i$ | $a_i$ | $b_i$ | $d_i$ |
|---|---|---|---|---|
| C — (3C, O) (alcohol) | 1 | −44.690 | 31.769 | −4.8791 |
| O — (H)(C) | 1 | 12.952 | −10.145 | 2.6261 |
| C — (3H)(C) | 3 | 3.8452 | −0.33997 | 0.19489 |
| | Sum | −20.202 | 20.604 | −1.668 |

$$C_p = \left(8.3143 \frac{\text{J}}{\text{mol}\cdot\text{K}}\right)\left[-20.202 + 20.604\left(\frac{304}{100}\right) - 1.668\left(\frac{340}{100}\right)^2\right]$$
$$= 254.16 \frac{\text{J}}{\text{mol}\cdot\text{K}}$$

This value is 0.7 percent higher than the DIPPR 801 recommended value of 252.40 J/(mol·K).

***Recommended Method 2*** Lee-Kesler.

*References:* [PGL5]

*Classification:* Corresponding states.

*Expected uncertainty:* 4 percent.

*Applicability:* Organic compounds other than those that are strongly polar or associate.

*Input data:* $T_c$, ω, and the ideal gas heat capacity at the same temperature.

*Description:* The isobaric liquid heat capacity is calculated at the reduced temperature $T_r$ using

$$\frac{C_p}{R} = \frac{C_p^o}{R} + 1.586 + \frac{0.49}{1 - T_r} + \omega\left[4.2775 + \frac{6.3(1 - T_r)^{1/3}}{T_r} + \frac{0.4355}{1 - T_r}\right] \tag{2-55}$$

***Example*** Calculate the isobaric liquid heat capacity for 1,4-dioxane at 320 K.

*Auxiliary data:* From the DIPPR 801 database: $T_c$ = 597.0 K, ω = 0.2793, and $C_p^o/R$ = 11.94. The reduced temperature is therefore $T_r$ = (320 K)/(597.0 K) = 0.536.

*From Eq. (2.55),*

$$\frac{C_p}{R} = 11.94 + 1.586 + \frac{0.49}{1 - 0.536} + (0.2793)\left[4.2775 + \frac{6.3(1 - 0.536)^{1/3}}{0.536} + \frac{0.4355}{1 - 0.536}\right] = 18.58$$

and $C_p$ = 154.5 J/(mol·K). This is 4.6 percent below the DIPPR recommended value of 162.0 J/(mol·K).

**TABLE 2-165 Benson* and CHETAH† Group Contributions for Ideal Gas Heat Capacity**

Table-specific nomenclature: Cb = carbon in benzene ring; Ct = carbon with a triple bond, (═C) = carbon with a double bond; Cp = carbon in fused ring; Naz = azide; Nim = imino.

**Solids** Solid heat capacity increases with increasing temperature and is proportional to $T^3$ near absolute zero. The heat capacity at a solid-solid phase transition becomes large, and there can be a substantial difference in the heat capacity of the two equilibrium solid phases that exist on either side of the transition temperature. The heat capacity generally rises steeply with increasing temperature near the triple point.

For a quick estimation of solid heat capacity specifically at 298.15 K, the very simple modification of Kopp's rule [Kopp, H., *Ann. Chem. Pharm.* (*Liebig*), **126** (1863): 362] by Hurst and Harrison [Hurst, J. E., and B. K. Harrison, *Chem. Eng. Comm.*, **112** (1992): 21] can be used. At other temperatures and to obtain the temperature dependence of the solid heat capacity, the method given below by Goodman et al. should be used.

***Recommended Method 1*** Goodman method.

*Reference:* Goodman, B. T., W. V. Wilding, J. L. Oscarson, and R. L. Rowley, *J. Chem. Eng. Data*, **49** (2004): 24.

*Classification:* Group contributions.

*Expected uncertainty:* 10 percent.

*Applicability:* Organic compounds for which group values are available.

*Input data:* Molecular structure and Table 2-167 group values.

*Description:*

$$\frac{C_p}{\mathrm{J/(mol\cdot K)}} = \frac{A}{1000}\left(\frac{T}{\mathrm{K}}\right)^{0.79267} \tag{2-56}$$

$$A = \exp\left(6.7796 + \sum_{i=1}^{N} n_i a_i + \sum_{i=1}^{N} n_i^2 \beta_i\right) \tag{2-57}$$

where $n_i$ = number of occurrences of group $i$

$a_i$ = individual group $i$ contribution

$\beta_i$ = nonlinear correction terms for chain and aromatic carbons

***Example*** Estimate the solid heat capacity for *p*-cresol at 307.93 K.

*Structure:*

*Group contributions:*

| Group | $n_i$ | $a_i$ | $\beta_i$ |
|---|---|---|---|
| —$CH_3$ | 1 | 0.20184 | 0 |
| Ar—CH═ | 4 | 0.082478 | −0.00033 |
| Ar >C═ | 2 | 0.012958 | 0 |
| —OH | 1 | 0.10341 | 0 |

*From Eq.* (*2-57*):

$$A = \exp\,[6.7796 + 0.20184 + (4)\,(0.082478) + (2)(0.012958) + 0.10341 + (4)^2(-0.00033)] = 1694.9$$

*From Eq.* (*2-56*):

$$C_p = \frac{1694.9}{1000}(307.93)^{0.79267}\frac{\mathrm{J}}{\mathrm{mol\cdot K}} = 159.1\frac{\mathrm{J}}{\mathrm{mol\cdot K}}$$

This value is 2.5 percent higher than the DIPPR 801 recommended value of 155.2 J/(mol·K).

***Recommended Method 2*** Modified Kopp's rule.

*Reference:* Kopp, H., *Ann. Chem. Pharm.* (*Liebig*), **126** (1863): 362; Hurst, J. E., and B. K. Harrison, *Chem. Eng. Comm.*, **112** (1992): 21.

Nonlinear Terms

| Groups | $\beta_i$ | Usage |
|---|---|---|
| >$CH_2$ | –0.00188 | Methylene |
| Ar═CH— | –0.00033 | Aromatic carbon |

*Goodman, B. T., W. V. Wilding, J. L. Oscarson, and R. L. Rowley, *J. Chem. Eng. Data*, **49** (2004): 24.

*Classification:* Group contributions.
*Expected uncertainty:* 10 percent.
*Applicability:* At 298.15 K; organic compounds that are solids at 298.15 K.
*Input data:* Compound chemical formula and element contributions of Table 2-168.
*Description:*

$$\frac{C_P}{\text{J/(mol·K)}} = \sum_{E=1}^{N} n_E \Delta_E \tag{2-58}$$

where $N$ = number of different elements in compound
$n_E$ = number of occurrences of element $E$ in compound
$\Delta_E$ = contribution of element $E$ from Table 2-168

***Example*** Estimate the solid heat capacity at 298.15 K for dibenzothiophene.
*Structure:* $C_{12}H_8S$.
*Group values from Table 2-168:*

$$\Delta_C = 10.89 \qquad \Delta_H = 7.56 \qquad \Delta_S = 12.36$$

*Calculation using Eq. (2-54):*

$$C_P = (12)(10.89) + (8)(7.56) + (1)(12.36) = 203.52 \text{ J/(mol·K)}$$

**TABLE 2-168 Element Contributions to Solid Heat Capacity for the Modified Kopp's Rule*†**

| Element | $\Delta_E$ | Element | $\Delta_E$ | Element | $\Delta_E$ |
|---|---|---|---|---|---|
| C | 10.89 | Ba | 32.37 | Mo | 29.44 |
| H | 7.56 | Be | 12.47 | Na | 26.19 |
| O | 13.42 | Ca | 28.25 | Ni | 25.46 |
| N | 18.74 | Co | 25.71 | Pb | 31.60 |

| I | 25.29 | Li | 23.25 | W | 30.87 |
| Al | 18.07 | Mg | 22.69 | Zr | 26.82 |
| B | 10.10 | Mn | 28.06 | All others | 26.63 |

*Kopp, H., *Ann. Chem. Pharm.* (*Liebig*), **126** (1863): 362.
†Hurst, J. E., and B. K. Harrison, *Chem. Eng. Comm.*, **112** (1992): 21.

This value is 2.5 percent higher than the DIPPR 801 recommended value of 198.45 J/(mol·K).

**Mixtures** The molar heat capacity of liquid and vapor mixtures can be estimated as a mole fraction average of the pure-component values

$$C_{P,m} = \sum_{i=1}^{C} x_i C_{P,i} \tag{2-59}$$

This neglects the excess heat capacity, which, if available, can be added to the mole fraction average to improve the estimated value.

## DENSITY

*Density* is defined as the mass of a substance per unit volume. Density is given in kg/m$^3$ in SI units, but lb$_m$/ft$^3$ and g/cm$^3$ are common AES and cgs units, respectively. Other commonly used forms of density include *molar density* (density divided by molecular weight) in kmol/m$^3$, *relative density* (density relative to water at 15°C), and the older term *specific gravity* (density relative to water at 60°F). Often the inverse of density, *specific volume*, and the inverse of molar density, *molar volume*, are correlated and used to convey equivalent information.

**Gases** Gases/vapors are compressible and their densities are strong functions of both temperature and pressure. Equations of state (EoS) are commonly used to correlate molar densities or molar volumes. The most accurate EoS are those developed for specific fluids with parameters regressed from all available data for that fluid. Super EoS are available for some of the most industrially important gases and may contain 50 or more constants specific to that chemical. Different predictive methods may be used for gas densities depending upon the conditions:

1. At *very low densities* (high temperatures, generally above the critical, and very low pressures, generally below a few bar), the ideal gas EoS

$$Z \equiv \frac{PV}{RT} = 1 \tag{2-60}$$

may be applied.

2. At *moderate densities* (below 40 percent of the critical density), the virial equation truncated after the second virial coefficient

$$Z = 1 + \frac{B(T)}{V} \tag{2-61}$$

may be used. Second virial coefficients $B(T)$ are available in the DIPPR 801 database for many chemicals and can be estimated using the Tsonopoulos method.

***Recommended Method*** Tsonopoulos method.

*Reference:* Tsonopoulos, C., *AIChE J.*, **20** (1974): 263; **21** (1975): 827; **24** (1978): 1112.

*Classification:* Corresponding states.

*Expected uncertainty:* 8 percent for $B(T)$.

*Applicability:* Nonpolar organic compounds and some classes of polar compounds.

*Input data:* Class of fluid, $\omega$, $P_c$, $T_c$, and $\mu$.

*Description:*

$$\frac{BP_c}{RT_c} = B^{(0)} + \omega B^{(1)} + B^{(2)} \tag{2-62}$$

where

$$B^{(0)} = 0.1445 - \frac{0.330}{T_r} - \frac{0.1385}{T_r^2} - \frac{0.0121}{T_r^3} - \frac{0.000607}{T_r^8} \tag{2-63}$$

$$B^{(1)} = 0.0637 + \frac{0.331}{T_r^2} - \frac{0.423}{T_r^3} - \frac{0.008}{T_r^8} \tag{2-64}$$

$$B^{(2)} = \frac{a}{T_r^6} - \frac{b}{T_r^8} \tag{2-65}$$

$$\mu_r = \left(\frac{\mu}{\text{D}}\right)^2 \left(\frac{P_c}{\text{bar}}\right) \left(\frac{T_c}{\text{K}}\right)^{-2} \tag{2-66}$$

and $\mu$ = dipole moment. The values of $a$ and $b$ used in Eq. (2-65) depend upon the class of fluid, as given in the table below:

| Class | $a$ | $b$ |
|---|---|---|
| Nonpolar fluids | 0 | 0 |
| Ketones, aldehydes, nitriles, ethers, esters, $NH_3$, $H_2S$, HCN | $-21.4\mu_r - 4.308 \times 10^{19}\mu_r^8$ | 0 |
| Monoalkylhalides, mercaptans, sulfides | $-2.188 \times 10^{16}\mu_r^4 - 7.831 \times 10^{19}\mu_r^8$ | 0 |
| 1-Alcohols except methanol | 0.0878 | $0.00908 + 69.57\mu_r$ |
| Methanol | 0.0878 | 0.0525 |

***Example*** Estimate the molar volume of ammonia at 430 K and 2.82 MPa.

*Input properties:* Recommended values from the DIPPR 801 database are $T_c = 405.65$ K, $P_c = 11.28$ MPa, $\mu = 1.469$ D, and $\omega = 0.252608$.

*Reduced conditions:*

$$T_r = (430\text{ K})/(405.65\text{ K}) = 1.06$$

$$P_r = (2.82\text{ MPa})/(11.28\text{ MPa}) = 0.25$$

$$\mu_r = (1.469)^2(112.8)/(405.65)^2 = 0.0014793$$

*Second virial coefficient from Eqs. (2-63) to (2-66):*

$$B^{(0)} = 0.1445 - 0.330/1.06 - 0.1385/(1.06)^2 - 0.0121/(1.06)^3 - 0.000607/(1.06)^8 = -0.301$$

$$B^{(1)} = 0.0637 + 0.331/(1.06)^2 - 0.423/(1.06)^3 - 0.008/(1.06)^8 = -0.00189$$

$$a = (-21.4)(0.0014793) - (4.308 \times 10^{19})(0.0014793)^8 = -0.033$$

$$b = 0$$

$$B^{(2)} = (-0.033)/(1.06)^6 = -0.023$$

*From Eq. (2-62):*

$$BP_c/(RT_c) = -0.301 - (0.252608)(0.00189) - 0.023 = -0.324$$

$$B = (-0.324)[0.008314\text{ m}^3\cdot\text{MPa}/(\text{kmol}\cdot\text{K})](405.65\text{ K})/(11.28\text{ MPa}) = -0.097\text{ m}^3/\text{kmol}$$

*Molar volume from Eq. (2-61):*

$$V = \frac{RT}{P}\left(1 + \frac{B}{V}\right) = \frac{\left(0.0083143\,\frac{\text{m}^3\cdot\text{MPa}}{\text{kmol}\cdot\text{K}}\right)(430\text{ K})}{2.82\text{ MPa}}\left(1 + \frac{-0.097\,\frac{\text{m}^3}{\text{kmol}}}{V}\right) = 1.162\,\frac{\text{m}^3}{\text{kmol}}$$

Note that the ideal gas value, 1.268 $m^3$/kmol, deviates by 9.1 percent from this more accurate value. The truncated virial EoS should be valid for this density since $\rho = V^{-1} = 0.86$ kmol/$m^3$ is much less than 40 percent of the critical density (the DIPPR 801 recommended value for the critical density is 13.8 kmol/$m^3$).

3. For *higher gas densities*, the Lee-Kesler method described below provides excellent predictions for nonpolar and slightly polar fluids. Extended four-parameter corresponding-states methods are available for polar and slightly associating compounds.

***Recommended Method*** Lee-Kesler method.

*Reference:* Lee, B. I., and M. G. Kesler, *AIChE J.*, **21** (1975): 510.

*Classification:* Corresponding states.

*Expected uncertainty:* 1 percent except near the critical point where errors can be up to 30 percent.

*Applicability:* Nonpolar and moderately polar compounds. An extended Lee-Kesler method, not described here, may be used for polar and slightly associating compounds [Wilding, W. V., and R. L. Rowley, *Int. J. Thermophys.*, **8** (1986): 525].

*Input data:* $T_c$, $P_c$, $\omega$, $Z^{(0)}$, $Z^{(1)}$.

*Description:*

$$Z = Z^{(0)} + \omega Z^{(1)} \tag{2-67}$$

where $Z$ = compressibility factor
$Z^{(0)}$ = compressibility factor of simple fluid obtained from Table 2-169
$Z^{(1)}$ = deviation from simple fluid obtained from Table 2-170

Analytical expressions for $Z^{(0)}$ and $Z^{(1)}$ can also be generated by using

$$Z^{(0)} = Z_0 \qquad Z^{(1)} = \frac{Z_1 - Z_0}{0.3978} \tag{2-68}$$

where $Z_0$ and $Z_1$ are determined from

$$\begin{aligned} Z_i &= \frac{P_r V_r}{T_r} = 1 + \frac{B}{V_r} + \frac{C}{V_r^2} + \frac{D}{V_r^5} + \frac{c_4}{T_r^3 V_r^2}\left(\beta + \frac{\gamma}{V_r^2}\right)\exp\left(\frac{-\gamma}{V_r^2}\right) \\ B &= b_1 - \frac{b_2}{T_r} - \frac{b_3}{T_r^2} - \frac{b_4}{T_r^3} \\ C &= c_1 - \frac{c_2}{T_r} + \frac{c_3}{T_r^2} \\ D &= d_1 + \frac{d_2}{T_r} \end{aligned} \tag{2-69}$$

as applied to the simple reference fluid and to the acentric reference fluid (*n*-octane), respectively. The constants for Eq. (2-69) for the two reference fluids are given in Table 2-171.

***Example*** Estimate the molar volume of saturated *n*-decane vapor at 540.5 K.

*Input properties:* Recommended values from the DIPPR 801 database are $T_c = 617.7$ K, $P_c = 2.11$ MPa, $P^{sat}(540.5\text{ K}) = 0.6799$ MPa, and $\omega = 0.492328$.

*Reduced conditions:*

$$T_r = (540.5\text{ K})/(617.7\text{ K}) = 0.875 \quad \text{and} \quad P_r = (0.6799\text{ MPa})/(2.11\text{ MPa}) = 0.322$$

*LK compressiblity factor:* Since vapor phase values are needed, the appropriate values from Tables 2-169 and 2-170 that can be used to double-interpolate are as follows:

| $Z^{(0)}$ | | |
|---|---|---|
| $T_r \backslash P_r$ | 0.2 | 0.4 |
| 0.85 | 0.8810 | (0.7222) |
| 0.90 | 0.9015 | 0.7800 |

| $Z^{(1)}$ | | |
|---|---|---|
| $T_r \backslash P_r$ | 0.2 | 0.4 |
| 0.85 | −0.0715 | (−0.1503) |
| 0.90 | −0.0442 | −0.1118 |

Double linear interpolation within these values gives $Z^{(0)} = 0.8058$ and $Z^{(1)} = -0.1025$.

*From Eq. (2-67):*

$$Z = 0.8058 + (0.492328)(-0.1025) = 0.7553$$

*Note:* If the analytical form available in Eq. (2-69) is used, the following more accurate values are obtained: $Z^{(0)} = 0.8131$, $Z^{(1)} = -0.1067$, and $Z = 0.7606$.

*Molar volume:*

$$V = \frac{ZRT}{P} = \frac{(0.7553)\left(0.0083143\,\frac{\text{m}^3\cdot\text{MPa}}{\text{kmol}\cdot\text{K}}\right)(540.5\text{ K})}{0.6799\text{ M Pa}} = 4.992\,\frac{\text{m}^3}{\text{kmol}}$$

4. *Cubic EoS* can be used to obtain both vapor and liquid densities as an alternative method to those mentioned above.

**TABLE 2-169 Simple Fluid Compressibility Factors $Z^{(0)}$**

Values in parentheses are for the opposite phase and may be used to interpolate to or near the phase boundary [PGL4; Wilding, W. V., J. K. Johnson, and R. L. *Rowley, Int. J. Thermophys.*, **8**(1987):717].

*Lee, B. I., and M. G. Kesler, *AIChE J.*, **21** (1975): 510.

***Recommended Method*** Cubic EoS.

*Classification:* Empirical extension of theory.

*Expected uncertainty:* Varies depending upon compound and conditions, but a general expectation is 10 to 20 percent.

*Applicability:* Nonpolar and moderately polar compounds.

*Input data:* $T_c$, $P_c$, ω.

*Description:* The more common cubic EoS can be written in the form

$$Z = \frac{V}{V-b} - \frac{V}{V^2+\delta V+\varepsilon}\,\frac{a\alpha(T_r)}{RT} \tag{2-70}$$

where $a$, $b$, δ, and ε are constants that depend upon the model EoS chosen, as does the temperature dependence of the function $\alpha(T_r)$. Definitions of these constants and $\alpha(T_r)$ for some of the more commonly used EoS models are shown in Table 2-172. The corresponding relations for many other EoS models in this same form are available [Soave, G., *Chem. Eng. Sci.*, **27** (1972): 1197]. The independent parameters $a$ and $b$ in these models can be regressed from experimental data to correlate densities or can be obtained from known critical constants to predict density data.

Of the cubic EoS given in Table 2-172, the Soave and Peng-Robinson are the most accurate, but there is no general rule for which EoS produces the best estimated volumes for specific fluids or conditions. The Peng-Robinson equation has been better tuned to liquid densities, while the Soave equation has been better tuned to vapor-liquid equilibrium and vapor densities. In solving the cubic equation for volume, a convenient initial guess to find the vapor root is the ideal gas value, while an initial value of 1.05$b$ is convenient to locate the liquid root.

***Example*** Estimate the molar density of liquid and vapor saturated ammonia at 353.15 K, using the Soave and Peng-Robinson EoS.

*Required properties:* Recommended values in the DIPPR 801 database are

$$T_c = 405.65\text{ K} \qquad P_c = 112.8\text{ bar} \qquad \omega = 0.252608$$

$$P^*(353.15\text{ K}) = 41.352\text{ bar (vapor pressure at 353.15 K)}$$

*EoS parameters (shown for Soave EoS):*

$$a = \frac{0.42748\,(RT_c)^2}{P_c} = \frac{0.42748\left[\left(83.145\,\frac{\text{bar}\cdot\text{cm}^3}{\text{mol}\cdot\text{K}}\right)(405.65\text{ K})\right]^2}{112.8\text{ bar}} = 4.311\times10^6\,\frac{\text{cm}^6\cdot\text{bar}}{\text{mol}^2}$$

$$b = \frac{0.08664\,(RT_c)}{P_c} = \frac{0.08664\left(83.145\,\frac{\text{bar}\cdot\text{cm}^3}{\text{mol}\cdot\text{K}}\right)(405.65\text{ K})}{112.8\text{ bar}} = 25.906\,\frac{\text{cm}^3}{\text{mol}}$$

$T_r = (353.15\text{ K})/(405.65\text{ K}) = 0.871$

$\alpha = \{1 + [0.48 + (1.574)(0.252608) - (0.176)(0.252608)^2]\,[1 - (0.871)^{0.5}]\}^2 = 1.119$

*Rearrange and solve Eq. (2-70) for V:*

$$P = \frac{RT}{V-b} - \frac{a\alpha}{V(V+b)} \qquad \text{or} \qquad PV^3 - RTV^2 + (a\alpha - bRT - Pb^2)V - ab\alpha = 0$$

$$41.352\left(\frac{V}{\text{m}^3/\text{mol}}\right)^3 - \left(0.029\,\frac{\text{m}^3}{\text{mol}}\right)\left(\frac{V}{\text{m}^3/\text{mol}}\right)^2 + \left(4.037\times10^{-6}\,\frac{\text{m}^6}{\text{mol}^2}\right)\left(\frac{V}{\text{m}^3/\text{mol}}\right) - 1.25\times10^{-10} = 0$$

*Vapor root (initial guess of $V = 7.1\times10^{-7}$ m³/mol from ideal gas equation):*

$$V_{\text{vap}} = 5.395\times10^{-4}\text{ m}^3/\text{mol} \quad \text{and} \quad \rho_{\text{vap}} = 1/V_{\text{vap}} = 1.854\text{ kmol/m}^3$$

*Liquid root (initial guess of $V = 2.72\times10^{-5}$ m³/mol from 1.05b):*

$$V_{\text{liq}} = 4.441\times10^{-5}\text{ m}^3/\text{mol} \qquad \text{and} \qquad \rho_{\text{liq}} = 1/V_{\text{liq}} = 22.516\text{ kmol/m}^3$$

*The corresponding values and equation for the Peng-Robinson EoS are*

$$a = 4.611\times10^6\text{ cm}^6\cdot\text{bar/mol}^2 \qquad b = 23.262\text{ cm}^3/\text{mol} \qquad \alpha = 1.103$$

$$P = \frac{RT}{V-b} - \frac{a\alpha}{V^2+2bV-b^2}$$

or

$$PV^3 + (bP-RT)V^2 + (a\alpha - 2bRT - 3Pb^2)V + (bP^3 + RTb^2 - ab\alpha) = 0$$

$$41.352\left(\frac{V}{\text{m}^3/\text{mol}}\right)^3 - \left(0.0284\,\frac{\text{m}^3}{\text{mol}}\right)\left(\frac{V}{\text{m}^3/\text{mol}}\right)^2 + \left(3.651\times10^{-6}\,\frac{\text{m}^6}{\text{mol}^2}\right)\left(\frac{V}{\text{m}^3/\text{mol}}\right) - 1.018\times10^{-10} = 0$$

*Solve for the two physical roots of this equation:*

$$V_{\text{vap}} = 5.286\times10^{-4}\text{ m}^3/\text{mol and } \rho_{\text{vap}} = 1.892\text{ kmol/m}^3$$

$$V_{\text{liq}} = 3.914\times10^{-5}\text{ m}^3/\text{mol and } \rho_{\text{liq}} = 25.55\text{ kmol/m}^3$$

The liquid density calculated from the Soave EoS is 24.2 percent below the DIPPR 801 recommended value of 29.69 kmol/m³; that calculated from the Peng-Robinson EoS is 13.9 percent below the recommended value.

**Liquids** For most liquids, the saturated molar liquid density ρ can be effectively correlated with

$$\rho = \frac{A}{B^{[1+(1-T/C)^D]}} \tag{2-71}$$

adapted from the Rackett prediction equation [Rackett, H. G., *J. Chem. Eng. Data*, **15** (1970): 514]. The regression constants *A, B,* and *D* are determined from the nonlinear regression of available data, while *C* is usually taken as the critical temperature. The liquid density decreases approximately linearly from the triple point to the normal boiling point and then nonlinearly to the critical density (the reciprocal of the critical volume). A few compounds such as water cannot be fit with this equation over the entire range of temperature.

The recommended method for estimation of saturated liquid density for pure organic compounds is the Rackett prediction method.

***Recommended Method*** Rackett method.

*Reference:* Rackett, H. G., *J. Chem. Eng. Data*, **15** (1970): 514.

*Classification:* Corresponding states.

*Expected uncertainty:* 15 percent as purely predictive equation; 2 percent if a liquid density value is available.

**TABLE 2-172 Relationships for Eq. (2-70) for Common Cubic EoS**

| EoS | δ | ε | $\alpha(T_r)$ | $aP_c/(RT_c)^2$ | $bP_c/(RT_c)$ |
|---|---|---|---|---|---|
| van der Waals* | 0 | 0 | 1 | 0.42188 | 0.125 |
| Relich-Kwong† | 0 | 0 | $T_r^{-0.5}$ | 0.42748 | 0.08664 |
| Soave‡ | $b$ | 0 | $[1 + (0.48 + 1.574\omega - 0.176\omega^2)(1 - T_r^{0.5})]^2$ | 0.42748 | 0.08664 |
| Peng-Robinson§ | $2b$ | $-b^2$ | $[1 + (0.37464 + 1.54226\omega - 0.2699\omega^2)(1 - T_r^{0.5})]^2$ | 0.45724 | 0.0778 |

*van der Waal, J. H., *Z. Phys. Chem.*, **5** (1890): 133.
†Redlich, O., and J. N. S. Kwong, *Chem. Rev.*, **44** (1949): 233.
‡Soave, G., *Chem. Eng. Sci.*, **27** (1972): 1197.
§Peng, D. Y., and D. B. Robinson, *Ind. Eng. Chem. Fundam.*, **15** (1976): 59.

*Applicability:* Saturated liquid densities of organic compounds.
*Input data:* $T_c$, $P_c$, and $Z_c$ (or, equivalently, $V_c$).
*Description:* A predictive form of the equation is given by

$$\frac{1}{\rho} = V = \left(\frac{RT_c}{P_c}\right) Z_c^q \qquad \text{where } q = 1 + (1 - T_r)^{2/7} \tag{2-72}$$

When one or more liquid density data points are available, $Z_c$ in Eq. (2-72) can be replaced with an adjustable parameter fitted from the data ($Z_{RA}$ in the notation of Spencer and Danner [Spencer, C. F., and R. P. Danner, *J. Chem. Eng. Data* **17** (1972): 236]). This produces densities in good agreement with experiment and permits accurate interpolation of the densities over most of the liquid temperature range, but it does not give the correct critical density unless $Z_{RA} = Z_c$.

***Example*** Estimate the saturated liquid density of acetonitrile at 376.69 K.
*Required properties:* The recommended values from the DIPPR 801 database are

$$T_c = 545.5 \text{ K} \qquad P_c = 4.83 \text{ MPa} \qquad Z_c = 0.184$$

*Calculate supporting quantities:*

$$T_r = (376.69 \text{ K})/(545.5 \text{ K}) = 0.691$$

$$q = 1 + (1 - 0.691)^{2/7} = 1.715$$

*Calculate saturated liquid density from Eq. (2-72):*

$$\rho = \left[\frac{4.83 \times 10^6 \text{ Pa}}{\left(8.314 \dfrac{\text{Pa} \cdot \text{m}^3}{\text{mol} \cdot \text{K}}\right)(545.5 \text{ K})}\right](0.184)^{-1.715} = 19.42 \frac{\text{kmol}}{\text{m}^3}$$

The estimated density is 16 percent above the DIPPR 801 value of 16.73 kmol/m$^3$.

*Calculate $\rho_{sat}$ from Eq. (2-72) with a known liquid density:* Kratzke and Muller [Kratzke, H., and S. Muller, *J. Chem. Thermo.*, **17** (1985): 151] reported an experimental density of 18.919 kmol/m$^3$ at 298.08 K. Use of this experimental value in Eq. (2-72) to calculate $Z_{RA}$ gives

$$T_r = (298.08 \text{ K})/(545.5 \text{ K}) = 0.546 \qquad q = 1 + (1 - 0.546)^{2/7} = 1.798$$

$$Z_{RA} = \left[\frac{4.83 \times 10^6 \text{ Pa}}{\left(8.314 \dfrac{\text{Pa} \cdot \text{m}^3}{\text{kmol} \cdot \text{K}}\right)(545.5 \text{ K})\left(18.919 \dfrac{\text{kmol}}{\text{m}^3}\right)}\right]^{1/1.798} = 0.202$$

$$\rho = \left[\frac{4.83 \times 10^6 \text{ Pa}}{\left(8.314 \dfrac{\text{Pa} \cdot \text{m}^3}{\text{mol} \cdot \text{K}}\right)(545.5 \text{ K})}\right](0.202)^{-1.715} = 16.577 \frac{\text{kmol}}{\text{m}^3}$$

The value obtained by the modified Rackett method is 0.9 percent below the DIPPR 801 recommended value. Note, however, that with $Z_{RA} = 0.202$ instead of $Z_c$, Eq. (2-72) gives $\rho_c = 5.28$ kmol/m$^3$ instead of $\rho_c = P_c/(Z_c RT_c) = 5.79$ kmol/m$^3$.

**Solids** Solid density data are sparse and usually available only within a narrow temperature range. For most solids, density decreases approximately linearly with increasing temperature. No accurate method for prediction of solid densities is available, but an approximate correlation has been found between the density of the liquid phase at the triple point and the solid that is stable at the triple point conditions.

***Recommended Method*** Goodman method.
*Reference:* Goodman, B. T., W. V. Wilding, J. L. Oscarson, and R. L. Rowley, *J. Chem. Eng. Data*, **49** (2004): 1512.
*Classification:* Empirical correlation.
*Expected uncertainty:* 6 percent.
*Applicability:* Organic compounds; applicable to the stable solid phase at the triple point temperature $T_t$; applicable $T$ range is from $T_t$ down to either the first solid-phase transition temperature or to approximately $0.3T_t$.
*Input data:* Liquid density at the triple point.
*Description:* The density for the solid phase that is stable at the triple point has been correlated as a function of temperature and the liquid density at $T_t$ as

$$\rho_s = \left(1.28 - 0.16 \frac{T}{T_t}\right) \rho_L(T_t) \tag{2-73}$$

***Example*** Estimate the density of solid naphthalene at 281.46 K.
*Required properties:* The recommended values from the DIPPR 801 database for $T_t$ and the liquid density at $T_t$ are

$$T_t = 353.43 \text{ K} \qquad \rho_L(T_t) = 7.6326 \text{ kmol/m}^3$$

*From Eq. (2-73):*

$$\rho_s = \left(1.28 - 0.16 \frac{281.46 \text{ K}}{353.43 \text{ K}}\right)\left(7.6326 \frac{\text{kmol}}{\text{m}^3}\right) = 8.797 \frac{\text{kmol}}{\text{m}^3}$$

The estimated value is 4.3 percent lower than the DIPPR 801 recommended value of 9.1905 kmol/m$^3$.

**Mixtures** Both liquid and vapor densities can be estimated using pure-component CS and EoS methods by treating the fluid as a pseudo-pure component with effective parameters calculated from the pure-component parameters using ad hoc mixing rules.

To apply the Lee-Kesler CS method to mixtures, pseudo-pure fluid constants are required. One of the simplest set of mixing rules for these quantities is [Prausnitz, J. M., and R. D. Gunn, *AIChE J.*, **4** (1958): 430, 494; Joffe, J., *Ind. Eng. Chem. Fundam.*, **10** (1971): 532]:

$$\overline{T}_c = \sum_{i=1}^{C} x_i T_{c,i} \tag{2-74}$$

$$\overline{P}_c = \frac{\sum_{i=1}^{C} x_i Z_{c,i}}{\sum_{i=1}^{C} x_i V_{c,i}} R\overline{T}_c \tag{2-75}$$

$$\overline{\omega} = \sum_{i=1}^{C} x_i \omega_i \tag{2-76}$$

The procedures are identical to those for pure components with the replacement of $T_c$, $P_c$, and $\omega$ with the effective mixture values obtained from the above equations.

To use a cubic EoS for a mixture, mixing rules are used to calculate effective mixture parameters in terms of the pure-component values. Although more complex mixing rules may improve prediction accuracy, the simple forms recommended here provide reasonable accuracy without adjustable parameters:

$$\overline{b} = \sum_{i=1}^{C} x_i b_i \tag{2-77}$$

$$\overline{a\alpha} = \left[\sum_{i=1}^{C} x_i (a_i \alpha_i)^{1/2}\right]^2 \tag{2-78}$$

Mixture calculations are then identical to the pure-component calculations using these effective mixture parameters for the pure-component $a\alpha$ and $b$ values.

The modified Rackett method has also been extended to liquid mixtures [Spencer, C. F., and R. P. Danner, *J. Chem. Eng. Data*, **17** (1972): 236] using the following combining and mixing rules as modified by Li [Li, C. C., *Can. J. Chem. Eng.*, **19** (1971): 709]:

$$T_{c,ij} = \sqrt{T_{c,i} T_{c,j}} \qquad \phi_i = \frac{x_i V_{c,i}}{\sum_{j=1}^{C} x_j V_{c,j}} \qquad \overline{T}_c = \sum_{i=1}^{C} \sum_{j=1}^{C} \phi_i \phi_j T_{c,ij} \tag{2-79}$$

***Recommended Method*** Spencer-Danner-Li mixing rules with Rackett equation.
*References:* Spencer, C. F., and R. P. Danner, *J. Chem. Eng. Data*, **17** (1972): 236; Li, C. C., *Can. J. Chem. Eng.*, **19** (1971): 709.
*Classification:* Corresponding states.
*Expected uncertainty:* About 7 percent on average; higher near the $T_c$ of any of the components.
*Applicability: Saturated* (at the bubble point) liquid mixtures.
*Input data:* $T_c$, $V_c$, and $x_i$.
*Description:* The predictive form of the equation is given by

$$\frac{1}{\rho} = V = R\left(\sum_{i=1}^{C} \frac{x_i T_{c,i}}{P_{c,i}}\right) \overline{Z}_{RA}^{q} \qquad q = 1.0 + (1.0 - T_r)^{2/7} \tag{2-80}$$

where

$$\bar{Z}_{RA} = 0.29056 - 0.08775 \sum_{i=1}^{C} x_i \omega_i \quad \text{and} \quad T_r = \frac{T}{\bar{T}_c} \tag{2-81}$$

***Example*** Estimate the saturated liquid density of a liquid mixture of 50 mol% ethane(1) and 50 mol% *n*-decane(2) at 377.6 K.

*Required properties:* The recommended values from the DIPPR 801 database for the required properties are as follows:

| | $T_c$/K | $V_c$/(m$^3$ · kmol$^{-1}$) | $P_c$/bar | ω |
|---|---|---|---|---|
| Ethane | 305.32 | 0.1455 | 48.72 | 0.0995 |
| Decane | 617.7 | 0.617 | 21.1 | 0.4923 |

*Auxiliary quantities from Eq. (2-79):*

$$\phi_1 = \frac{(0.5)(0.1455)}{(0.5)(0.1455)+(0.5)(0.617)} = 0.191; \quad \phi_2 = 0.809$$

$$T_{c,12} = \sqrt{(305.32\ \text{K})(617.7\ \text{K})} = 434.3\ \text{K}$$

$$\frac{\bar{T}_c}{\text{K}} = \phi_1^2 T_{c,1} + 2\phi_1\phi_2 T_{c,12} + \phi_2^2 T_{c,2}$$

$$= (0.191)^2(305.32) + (2)(0.191)(0.809)(434.3) + (0.809)^2(617.7)$$

$$\bar{T}_c = 549.68\ \text{K}$$

*Calculations from Eqs. (2-80) and (2-81):*

$$T_r = (377.6\ \text{K})/(549.63\ \text{K}) = 0.687 \quad q = 1 + (1 - 0.687)^{2/7} = 1.718$$

$$\bar{Z}_{RA} = 0.29056 - 0.08775[(0.5)(0.0995) + (0.5)(0.4923)] = 0.2646$$

$$V = \left(0.08314 \frac{\text{m}^3 \cdot \text{bar}}{\text{K} \cdot \text{kmol}}\right)\left[\frac{(0.5)(305.32\ \text{K})}{48.72\ \text{bar}} + \frac{(0.5)(617.7\ \text{K})}{21.1\ \text{bar}}\right](0.2646)^{1.718} = 0.151 \frac{\text{m}^3}{\text{kmol}}$$

The experimental value [Reamer, H. H., and B. H. Sage, *J. Chem. Eng. Data*, **7** (1962): 161] is 0.149 m$^3$/kmol, and the error in the estimated value is 1.3 percent.

## VISCOSITY

*Viscosity* is defined as the shear stress per unit area at any point in a confined fluid, divided by the velocity gradient in the direction perpendicular to the direction of flow. The *absolute viscosity* η is the shear stress at a point, divided by the velocity gradient at that point. The SI unit of viscosity is Pa · s [1 kg/(m · s)], but the cgs units of poise (P) [1 g/(cm · s)] and centipoise (cP = 0.01 P) are also frequently used (1 cP = 1 mPa · s). The *kinematic viscosity* ν is defined as the ratio of the absolute viscosity to density at the same temperature and pressure. The SI unit for ν is m$^2$/s, but again cgs units are very common and ν is often given in stokes (1 St = 1 cm$^2$/s) or centistokes (1 cSt = 0.01 cm$^2$/s).

**Gases** Experimental data for gases and vapors at low density are often correlated with

$$\eta^o = \frac{AT^B}{1 + C/T + D/T^2} \tag{2-82}$$

Over smaller temperature ranges, parameters $C$ and $D$ may not be necessary as ln(η) is often reasonably linear with ln($T$). Care should be taken in extrapolating using Eq. (2-82) as there can be unintended mathematical poles where the denominator approaches zero.

Numerous methods have been developed for estimation of vapor viscosity. For nonpolar vapors, the Yoon-Thodos CS method works well, but for polar fluids the Reichenberg method is preferred. Both methods are illustrated below.

***Recommended Method 1*** Yoon-Thodos method.
*Reference:* Yoon, P., and G. Thodos, *AIChE J.*, **16** (1970): 300.
*Classification:* Corresponding states.
*Expected uncertainty:* 5 percent.
*Applicability:* Nonpolar and slightly polar organic vapors.
*Input data:* $T_c$, $P_c$, and $M$.
*Description:* The correlation for viscosity as a function of reduced temperature is

$$\frac{\eta^o}{\text{Pa} \cdot \text{s}} = \frac{46.1 T_r^{0.618} - 20.4\ \exp(-0.449 T_r) + 19.4\ \exp(-4.058\, T_r) + 1}{2.173424 \times 10^{11} (T_c/\text{K})^{1/6} (M/\text{g} \cdot \text{mol}^{-1})^{-1/2} (P_c/\text{Pa})^{-2/3}} \tag{2-83}$$

***Example*** Estimate the low-pressure vapor viscosity of propane at 353 K.
*Required constants:* The DIPPR 801 database recommends the following values:

$$T_c = 369.83\ \text{K} \qquad P_c = 4.248\ \text{MPa} \qquad M = 44.0956\ \text{g/mol}$$

*Reduced temperature:*

$$T_r = (353\ \text{K})/(369.83\ \text{K}) = 0.9545$$

*Calculation using Eq. (2-83):*

$$\frac{\eta^o}{\text{Pa} \cdot \text{s}} = \frac{(46.1)(0.9545)^{0.618} - 20.4 \exp[-(0.449)(0.9545)] + 19.4 \exp[-4.058(0.9545)] + 1}{(2.173424 \times 10^{11})(369.83)^{-1/6}(44.0956)^{-1/2}(4.248 \times 10^6)^{-2/3}}$$

$$= 9.84 \times 10^{-6}$$

This value is 1.5 percent higher than the DIPPR 801 recommended value of $9.70 \times 10^{-6}$ Pa · s.

***Recommended Method 2*** Reichenberg method.
*Reference:* Reichenberg, D., *AIChE J.*, **21** (1975): 181.
*Classification:* Group contributions and corresponding states.
*Expected uncertainty:* 5 percent.
*Applicability:* Nonpolar and polar organic and inorganic vapors.
*Input data:* $T_c$, $P_c$, $M$, μ, and molecular structure.
*Description:* The temperature dependence of the viscosity is given by

$$\frac{\eta^o}{\text{Pa} \cdot \text{s}} = \frac{A T_r^2}{[1 + 0.36\, T_r (T_r - 1)]^{1/6}} \left[\frac{1 + 270(\mu_r^*)^4}{T_r + 270(\mu_r^*)^4}\right] \tag{2-84}$$

where the parameter $A$ is determined from group contributions and the modified reduced dipole $\mu_r^*$ is found from

$$\mu_r^* = 52.46 \mu_r \tag{2-85}$$

and Eq. (2-66).

For organic compounds, $A$ is found from the group values $C_i$, listed in Table 2-173, using

$$A = 10^{-7} \frac{\left(\dfrac{M}{\text{kg/kmol}}\right)^{1/2} (T_c/\text{K})}{\displaystyle\sum_{i=1}^{N} n_i C_i} \tag{2-86}$$

For inorganic gases, $A$ is obtained from

$$A = 1.6104 \times 10^{-10} \left[\left(\frac{M}{\text{g/mol}}\right)^{1/2} \left(\frac{P_c}{\text{Pa}}\right)^{2/3} \left(\frac{T_c}{\text{K}}\right)^{-1/6}\right] \tag{2-87}$$

**TABLE 2-173 Reichenberg* Group Contribution Values**

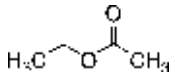
| Group | $C_i$ | Group | $C_i$ |
|---|---|---|---|
| —$CH_3$ | 9.04 | —F | 4.46 |
| >$CH_2$ | 6.47 | —Cl | 10.06 |
| >CH— | 2.67 | —Br | 12.83 |
| >C< | –1.53 | —OH alcohol | 7.96 |
| ═$CH_2$ | 7.68 | >O | 3.59 |
| ═CH— | 5.53 | >C═O | 12.02 |
| >C═ | 1.78 | —CHO | 14.02 |
| ≡CH | 7.41 | —COOH | 18.65 |
| ≡C— | 5.24 | —COO— or HCOO— | 13.41 |
| >$CH_2$ ring | 6.91 | —$NH_2$ | 9.71 |
| >CH— ring | 1.16 | >NH | 3.68 |
| >C< ring | 0.23 | ═N— ring | 4.97 |
| ═CH— ring | 5.90 | —CN | 18.13 |
| >C═ ring | 3.59 | >S ring | 8.86 |

*Reichenberg, D., *AIChE J.*, **21** (1975): 181.

***Example*** Estimate the low-pressure vapor viscosity of ethyl acetate at 401.25 K.
*Required constants:* The DIPPR 801 database recommends the following values:

$M = 88.1051$ g/mol $\quad T_c = 523.3$ K $\quad P_c = 3.88$ MPa $\quad \mu = 1.78$ *D*

*Supporting quantities:*
Structural groups:



| Group | $n_i$ | $C_i$ | Contribution |
|---|---|---|---|
| —$CH_3$ | 2 | 9.04 | 18.08 |
| >$CH_2$ | 1 | 6.47 | 6.47 |
| —COO— | 1 | 13.41 | 13.41 |
| | | Total | 37.96 |

$$T_r = (401.25\text{ K})/(523.3\text{ K}) = 0.767$$

*From Eqs. (2-66) and (2-85):*

$$\mu_r^* = 52.46\frac{(1.78)^2(38.8)}{(523.3)^2} = 0.024$$

*From Eq. (2-86):*

$$A = 10^{-7}\frac{(88.1051)^{1/2}(523.3)}{37.96} = 1.294\times10^{-5}$$

*Calculation using Eq. (2-84):*

$$\frac{\eta^o}{\text{Pa}\cdot\text{s}} = \frac{(1.294\times10^{-5})(0.767)^2}{[1+(0.36)(0.767)(0.767-1)]^{1/6}}\frac{1+(270)(0.024)^4}{0.767+(270)(0.024)^4} = 1.003\times10^{-5}$$

The estimated value is 1.5 percent lower than the DIPPR 801 recommended value of $1.018\times10^{-5}$ Pa·s.

The dependence of viscosity upon pressure is principally a density effect. Estimation of vapor viscosity at elevated pressures is commonly done by correlating density deviations from the low-pressure values estimated. Several methods are available, but the method developed by Jossi et al. and extended to polar fluids by Stiel and Thodos is relatively accurate and easy to apply.

***Recommended Method*** Jossi-Stiel-Thodos method.
*References:* Stiel, L. I., and G. Thodos, *AIChE J.*, **10** (1964): 26; Jossi, J. A., L. I. Stiel, and G. Thodos, *AIChE J.*, **8** (1962): 59.
*Classification:* Empirical correlation and corresponding states.
*Expected uncertainty:* 9 percent—often less for nonpolar gases, larger for polar gases.
*Applicability:* Nonassociating gases; $\rho_r < 2.6$.
*Input data: M*, $T_c$, $P_c$, $Z_c$, μ, $\eta^o$ (low-pressure viscosity at same *T* may be estimated by using methods given above), and ρ (may be calculated from *T* and *P* by using density methods given above).
*Description:* Deviation of η from the low-pressure value $\eta^o$ is given by one of the following correlations depending upon its polarity and reduced density range:
For nonpolar gases, $0.1 < \rho_r < 3.0$:

$$\left[\left(\frac{\eta-\eta^o}{\text{mPa}\cdot\text{s}}\right)\xi+1\right]^{1/4} = 1.0230+0.23364\rho_r+0.58533\rho_r^2-0.40758\rho_r^3+0.093324\rho_r^4 \qquad (2\text{-}88)$$

For polar gases, $\rho_r \le 0.1$:

$$\left(\frac{\eta-\eta^o}{\text{mPa}\cdot\text{s}}\right)\xi = 1.656\rho_r^{1.111} \qquad (2\text{-}89)$$

For polar gases, $0.1 < \rho_r \le 0.9$:

$$\left(\frac{\eta-\eta^o}{\text{mPa}\cdot\text{s}}\right)\xi = 0.0607\,(9.045\rho_r+0.63)^{1.739} \qquad (2\text{-}90)$$

For polar gases, $0.9 < \rho_r \le 2.2$:

$$\log\left\{4-\log\left[\left(\frac{\eta-\eta^o}{\text{mPa}\cdot\text{s}}\right)\xi\right]\right\} = 0.6439-0.1005\rho_r \qquad (2\text{-}91)$$

*For polar gases*, $2.2 < \rho_r \le 2.6$:

$$\log\left\{4-\log\left[\left(\frac{\eta-\eta^o}{\text{mPa}\cdot\text{s}}\right)\xi\right]\right\} = 0.6439-0.1005\rho_r-0.000475(\rho_r^3-10.65)^2 \qquad (2\text{-}92)$$

where $\rho_c = P_c/(Z_cRT_c)$ and

$$\xi = 2173.4\left(\frac{T_c}{\text{K}}\right)^{1/6}\left(\frac{M}{\text{kg/kmol}}\right)^{-1/2}\left(\frac{P_c}{\text{MPa}}\right)^{-2/3} \qquad (2\text{-}93)$$

***Example*** Estimate the vapor viscosity of $CO_2$ at 350 K and 20 MPa if $\eta^\circ = 0.0174$ mPa·s and $Z = 0.4983$ (estimated from Lee-Kesler method, see section on density).
*Required properties:* From the DIPPR 801 database,

$M = 44.01$ kg/kmol $\quad T_c = 304.21$ K $\quad P_c = 7.383$ MPa
$Z_c = 0.274 \quad \mu = 0$ D (nonpolar)

*Auxiliary quantities:*

$$\xi = (2173.4)(304.21)^{1/6}(44.01)^{-1/2}(7.383)^{-2/3} = 224.1$$

$$\rho_c = \frac{7.383\text{ MPa}}{0.274\,[0.008314\text{ m}^3\text{MPa}/(\text{K}\cdot\text{kmol})](304.21\text{ K})} = 10.654\frac{\text{kmol}}{\text{m}^3}$$

$$\rho_r = \frac{\rho}{\rho_c} = \frac{P}{ZRT\rho_c} = \frac{20\text{ MPa}}{0.4983[0.008314\text{m}^3\cdot\text{MPa}/(\text{K}\cdot\text{kmol})](350\text{ K})(10.654\text{ m}^3\cdot\text{kmol})} = 1.295$$

*Calculation using Eq. (2-88) for nonpolar fluids:*

$$\left[224.1\left(\frac{\eta-\eta^o}{\text{mPa}\cdot\text{s}}\right)+1\right]^{1/4} = 1.0230+0.23364(1.295)+0.58533(1.295)^2$$
$$-0.40758(1.295)^3+0.093324(1.295)^4 = 1.684$$
$$\eta = \frac{1.684^4-1}{224.1}\text{mPa}\cdot\text{s}+0.0174\text{ mPa}\cdot\text{s} = 0.0489\text{ mPa}\cdot\text{s}$$

This differs from the experimental value of 0.0473 mPa·s by 3.4 percent.

**Liquids** Liquid viscosity can be correlated as a function of temperature for low pressures. Usually the correlation is based on the Andrade equation [Andrade, E. N. da C., *Nature*, **125** (1930): 309]

$$\ln(\eta) = A+\frac{B}{T} \qquad (2\text{-}94)$$

or an extension of it. For example, the DIPPR 801 database uses the equation

$$\ln(\eta) = A+\frac{B}{T}+C\ln T+DT^E \qquad (2\text{-}95)$$

which is analogous to the Riedel [Riedel, L., *Chem. Ing. Tech.*, **26** (1954): 83] vapor pressure equation.

Currently the most accurate method for predicting pure liquid viscosity is the GC method by Hsu et al. It has been found that most liquids have a viscosity between 0.15 mPa·s (or cP) and 0.55 mPa·s at the normal boiling point, and this "rule" can be used as a valuable criterion to validate estimated viscosities as a function of temperature.

***Recommended Method*** Hsu method.
*Reference:* Hsu, H.-C., Y.-W. Sheu, and C.-H. Tu, *Chem. Eng. J.*, **88** (2002): 27.
*Classification:* Group contributions.
*Expected uncertainty:* 20 percent.
*Applicability:* Organic liquids; $T_r < 0.75$.
*Input data:* $P_c$ and molecular structure.
*Description:* The temperature dependence of the liquid viscosity is given by

$$\ln\left(\frac{\eta}{\text{mPa}\cdot\text{s}}\right) = \sum_{i=1}^{N}a_i+T\sum_{i=1}^{N}b_i+\frac{\sum_{i=1}^{N}c_i}{T^2}+\left(\sum_{i=1}^{N}d_i\right)\ln\left(\frac{P_c}{\text{bar}}\right) \qquad (2\text{-}96)$$

where $P_c$ is critical pressure and $a_i$, $b_i$, $c_i$, and $d_i$ are the group contributions obtained from Table 2-174.

***Example*** Estimate the liquid viscosity of benzotrifluoride at 303.15 K.

*Hsu, H.-C., Y.-W. Sheu, and C.-H. Tu, *Chem. Eng. J.*, **88** (2002): 27

*Supporting values:*

$$P_c = 32.1 \text{ MPa}$$

*Calculation using Eq. (2-96):*

$$\frac{\eta}{\text{mPa}\cdot\text{s}} = \exp\left[-0.9529 + (0.004067)(303.15) + \frac{230{,}463}{(303.15)^2} - 0.9460\ln(32.1)\right] = 0.610$$

The estimated value is 20 percent higher than the DIPPR 801 value of 0.509 mPa · s. Note that when the calculation is repeated at the normal boiling point (375.2 K), one obtains 0.343 mPa · s which is within the range of the aforementioned empirical rule.

**Liquid Mixtures** Most methods for estimating liquid mixture viscosity interpolate between the pure-component values at the same temperature. The Grunberg-Nissan equation [Grunberg, L., and A. H. Nissan, *Nature*, **164** (1949): 799]

$$\ln \eta = \sum_i^C x_i \ln \eta_i + \frac{1}{2}\sum_{i=1}^C \sum_{j=1}^C x_i x_j G_{ij} \qquad (2\text{-}97)$$

is commonly used for nonaqueous mixtures. The parameter $G_{ij}$ generally must be regressed from an experimental mixture viscosity. However, $G_{ij}$ can be set to zero for hydrocarbon mixtures with expected errors in the mixture viscosity of about 15 percent.

Estimation of liquid mixture viscosity without any mixture data is difficult because the viscosity is strongly affected by large molecular size differences and strong cross-interactions between different types of molecules. The UNIFAC-VISCO method described below can be used to predict liquid viscosity of organic mixtures without any mixture data. It can estimate mixture viscosity to a limited accuracy, but it is limited in scope by the small number of group contributions currently available.

***Recommended Method*** UNIFAC-VISCO method.

*Reference:* Chevalier, J. L., P. Petrino, and Y. Gaston-Bonhomme, *Chem. Eng. Sci.*, **43** (1988): 1303; Gaston-Bonhomme, Y., P. Petrino, and J. L. Chevalier, *Chem. Eng. Sci.*, **49** (1994): 1799.

*Classification:* Group contributions.

*Expected uncertainty:* 20 percent.

*Applicability:* Organic liquids.

*Input data:* Molecular structure; pure-component molar volumes and viscosities at the mixture temperature.

*Description:* Liquid mixture viscosity can be estimated in a manner similar to the UNIFAC method employed for mixture excess Gibbs energy and activity coefficients. The primary equation is

$$\ln\left(\frac{\eta}{\text{mPa}\cdot\text{s}}\right) = \sum_{i=1}^C x_i \ln\left(\frac{\eta_i}{\text{mPa}\cdot\text{s}}\cdot\frac{V_i}{V_m}\right) + \frac{g_c^E}{RT} - \frac{g_r^E}{RT} \qquad (2\text{-}98)$$

where $V_m$ is the mixture molar volume and $V_i$ is the pure-component molar volume of component $i$. The combinatorial and residual excess Gibbs energies are calculated as in the standard UNIFAC method for activity coefficients (see [PGL5]) and for brevity is not shown here. However, the group interactions $\psi_{mn}$ are calculated using the interaction parameters $\alpha_{mn}$ obtained from Table 2-175 in the equation

$$\psi_{mn} = \exp\left(-\frac{\alpha_{mn}}{298.15}\right) \qquad (2\text{-}99)$$

**TABLE 2-175 UNIFAC-VISCO* Group Interaction Parameters $\alpha_{mn}$**

| $CH_2$ | 0.6744 | 0.54 | 0 | 0 |
| $CH_{ar}$ | 0 | 0 | 3.1878 | 2.4 |
| OH | 1 | 1.2 | 0 | 0 |
| Total | 2.5755 | 2.588 | 3.1878 | 2.4 |

where in the above table

$$q_i = \sum_{k=1}^{N} N_{i,k} Q_k \quad \text{and} \quad r_i = \sum_{k=1}^{N} N_{i,k} R_k$$

$$\theta_1 = \frac{x_1 q_1}{\sum_{i=1}^{4} x_i q_i} = \frac{(0.5113)(2.588)}{(0.5113)(2.588)+(0.4887)(2.4)} = 0.53 \qquad \theta_2 = 0.47$$

$$\phi_1 = \frac{x_1 r_1}{\sum_{i=1}^{4} x_i r_i} = \frac{(0.5113)(2.5755)}{(0.5113)(2.5755)+(0.4887)(3.1878)} = 0.458 \qquad \phi_2 = 0.542$$

*UNIFAC combinatorial term:*

$$\frac{g_C^E}{RT} = \sum_{i=1}^{2} x_i \ln\frac{\phi_i}{x_i} + 5\sum_{i=1}^{2} x_i q_i \ln\frac{\theta_i}{\phi_i} = 0.124$$

*Group interactions:*

| | $\alpha_{mn}$ | | | |
|---|---|---|---|---|
| *m/n* group | $CH_3$ | $CH_2$ | $CH_{ar}$ | OH |
| $CH_3$ | 0 | −709.5 | −119.5 | 594.4 |
| $CH_2$ | 66.53 | 0 | 406.7 | 498.6 |
| $CH_{ar}$ | 237.2 | −623.7 | 0 | 419.3 |
| OH | 1209 | −634.5 | 197.7 | 0 |
| | $\psi_{mn}$ | | | |
| *m/n* group | $CH_3$ | $CH_2$ | $CH_{ar}$ | OH |
| $CH_3$ | 1.000 | 10.801 | 1.493 | 0.136 |
| $CH_2$ | 0.800 | 1.000 | 0.256 | 0.188 |
| $CH_{ar}$ | 0.451 | 8.100 | 1.000 | 0.245 |
| OH | 0.017 | 8.399 | 0.515 | 1.000 |

The $\alpha_{mn}$ values were obtained from Table 2-175, and $\psi_{mn}$ values were calculated from Eq. (2-99).

*Group fractions in the mixture:*

| Group | $N$ | $X$ | $XQ$ | $\Theta$ | $\ln\gamma$ |
|---|---|---|---|---|---|
| $CH_3$ | 0.5113 | 0.1145 | 0.097083 | 0.17370 | 0.293 |
| $CH_2$ | 0.5113 | 0.1145 | 0.061822 | 0.11061 | −0.873 |
| $CH_{ar}$ | 2.9322 | 0.6565 | 0.262618 | 0.46988 | 0.066 |
| OH | 0.5113 | 0.1145 | 0.137382 | 0.24581 | 1.077 |
| Sum | 4.4661 | | 0.558905 | | |

$$\text{Here } \Theta_m = \frac{X_m Q_m}{\sum_{i=1}^{4} X_i Q_i} \quad \text{and} \quad \ln\gamma_m = Q_m\left[1 - \ln\left(\sum_{i=1}^{4}\Theta_i\psi_{i,m}\right) - \sum_{i=1}^{4}\left(\frac{\Theta_i\psi_{m,i}}{\sum_{j=1}^{4}\Theta_j\psi_{j,i}}\right)\right]$$

*Group fractions in pure components:*

| | | | Ethanol | | |
|---|---|---|---|---|---|
| Group | $N$ | $X$ | $XQ$ | $\Theta$ | $\ln\gamma$ |
| $CH_3$ | 1 | 0.3333 | 0.283 | 0.3277 | 0.5306 |
| $CH_2$ | 1 | 0.3333 | 0.180 | 0.2087 | −0.9405 |
| $CH_{ar}$ | 0 | 0.0000 | 0.000 | 0.0000 | 0.2095 |
| OH | 1 | 0.3333 | 0.400 | 0.4637 | 0.6179 |
| Sum | 3 | | 0.863 | | |
| | | | Benzene | | |
| Group | $N$ | $X$ | $XQ$ | $\Theta$ | $\ln\gamma$ |
| $CH_3$ | 0 | 0 | 0 | 0 | 0.257 |
| $CH_2$ | 0 | 0 | 0 | 0 | −0.728 |
| $CH_{ar}$ | 6 | 1 | 0.4 | 1 | 0.000 |
| OH | 0 | 0 | 0 | 0 | 2.270 |
| Sum | 6 | | 0.4 | | |

The pure-component $\Theta$ and ln $\gamma$ equations are the same as shown above for the mixture groups.

*UNIFAC residual term:*

$$\frac{g_r^E}{RT} = \sum_{i=1}^{2} x_i\left[\sum_{m=1}^{4} N_{m,i}(\ln\gamma_m - \ln\gamma_{m,i})\right] = 0.3425$$

where $N_m$ and ln $\gamma_m$ refer to the mixture and $N_{m,i}$ and ln $\gamma_{m,i}$ refer to the pure-component values.

*Mixture volume:*

$$V_m = \sum_{i=1}^{2} x_i V_i = 0.5113\left(0.05862\frac{\text{m}^3}{\text{kmol}}\right) + 0.4887\left(0.08948\frac{\text{m}^3}{\text{kmol}}\right)$$
$$= 0.07370\frac{\text{m}^3}{\text{kmol}}$$

*Using Eq. (2-98):*

$$\ln\left(\frac{\eta}{\text{mPa}\cdot\text{s}}\right) = 0.5113\ln\left[1.0774\left(\frac{0.05862}{0.07370}\right)\right]$$
$$+ 0.4887\ln\left[0.5997\left(\frac{0.08948}{0.07370}\right)\right] + 0.124 - 0.3425 = -0.4523$$

$$\eta = \exp(-0.4523)\ \text{mPa}\cdot\text{s} = 0.636\ \text{mPa}\cdot\text{s}$$

The estimated value is 6.6 percent below the reported experimental value of 0.681 mPa·s [Kouris, S., and C. Panayiotou, *J. Chem. Eng. Data*, **34** (1989): 200].

## THERMAL CONDUCTIVITY

*Thermal conductivity*, $k$, is a measure of the rate at which heat conducts through the material and is defined as the proportionality constant in Fourier's law of heat conduction that relates the gradient of temperature to the heat flux or flow per unit area. In SI, it has the units of W/(m·K). The conduction mechanism in gases is primarily via molecular collisions, and $k$ increases with increasing temperature (increasing molecular velocity). The temperature dependence of low-pressure, gas-phase thermal conductivity is adequately correlated with

$$k = \frac{AT^B}{1 + \frac{C}{T}} \tag{2-100}$$

In dense media such as liquids, energy transfers more efficiently through the intermolecular force fields than through collisions. As a result, liquid thermal conductivity generally decreases with increasing temperature (except for water, aqueous solutions, and a few multihydroxy and multiamine compounds), corresponding to the decrease in density with increased temperature. The temperature dependence of liquid thermal conductivity at low to moderate pressures has been found to be well correlated by [Jamieson, D. T., *J. Chem. Eng. Data* **24** (1979): 244]

$$k = A(1 + B\tau^{1/3} + C\tau^{2/3} + D\tau) \tag{2-101}$$

where $\tau = 1 - T/T_C$. For nonassociating liquids, this equation can be simplified to two parameters by setting $C = 1 - 3B$ and $D = 3B$, generally without much loss in accuracy. Below or near the normal boiling point, the

temperature dependence of liquid thermal conductivity is nearly linear for modest temperature ranges and can be represented by

$$k = A - BT \tag{2-102}$$

where $B$ is generally in the range of $1 \times 10^{-4}$ to $3 \times 10^{-4}$ W/(m·K$^2$).

**Gases** Methods for estimating low-pressure gas thermal conductivities are based on kinetic theory and generally correlate the dimensionless group $kM/\eta C_v$ ($M$ = molecular weight, $\eta$ = viscosity, $C_v$ = isochoric heat capacity), known as the Eucken factor. The method of Stiel and Thodos is recommended for pure nonpolar compounds, and the method of Chung is recommended for pure polar compounds.

***Recommended Method*** Stiel-Thodos method.

*Reference:* Stiel, L. I., and G. Thodos, *AIChE J.*, **10** (1964): 26.

*Classification:* Empirical extension of theory.

*Expected uncertainty:* 15 percent.

*Applicability:* Pure nonpolar gases at low pressure.

*Input data: M*, $T_c$, $\eta$, and $C_v$.

*Description:* The following equations may be used depending upon the molecular shape:

$$\frac{kM}{\eta C_v} = 2.5 \qquad \text{monatomic} \tag{2-103}$$

$$\frac{kM}{\eta C_v} = 1.30 + \left(\frac{R}{C_v}\right)\left(1.7614 - \frac{0.3523}{T_r}\right) \qquad \text{linear molecules} \tag{2-104}$$

$$\frac{kM}{\eta C_v} = 1.15 + 2.033\left(\frac{R}{C_v}\right) \qquad \text{nonlinear molecules} \tag{2-105}$$

where $\eta$ = viscosity at same conditions as desired for $k$. Because this method is only applicable at low pressures, $C_v$ may usually be calculated as $C_p^o - R$, where $C_p^o$ is the ideal gas isobaric heat capacity.

***Example*** Estimate the low-pressure thermal conductivity of toluene vapor at 500 K.

*Required properties from the DIPPR 801 database:*

$T_c = 591.75$ K  $M = 92.138$ g/mol  $\eta(500\text{ K}) = 1.1408 \times 10^{-5}$ Pa·s

$C_v = C_p^o - R = (170.78 - 8.314)$ J/(mol·K) $= 162.47$ J/(mol·K)

*Auxiliary quantities:*

$T_r = 500/591.75 = 0.845$  $R/C_v = (8.314)/(162.47) = 0.0512$

*From Eq. (2-105):*

$$k = [1.15 + (2.033)(0.0512)]\left[\frac{(1.1408\times10^{-5}\ \text{Pa}\cdot\text{s})\left(162.47\ \frac{\text{J}}{\text{mol}\cdot\text{K}}\right)}{92.138\ \frac{\text{g}}{\text{mol}}}\right] = 25.2\ \frac{\text{mW}}{\text{m}\cdot\text{K}}$$

The estimated value is 18 percent below the DIPPR 801 value of 30.76 mW/(m·K).

***Recommended Method*** Chung-Lee-Starling method.

*Reference:* Chung, T.-H., L. L. Lee, and K. E. Starling, *Ind. Eng. Chem. Fundam.*, **23** (1984): 8.

*Classification:* Corresponding states.

*Expected uncertainty:* 15 percent.

*Applicability:* Pure organic gases at low pressure.

*Input data:* $C_v$, $\omega$, $T_c$, $M$, and $\eta$.

*Description:* The following equations apply:

$$\frac{kM}{\eta C_v} = 3.75\ \Psi\left(\frac{R}{C_v}\right) \tag{2-106}$$

$$\Psi = 1 + \alpha\left(\frac{0.215 + 0.28288\alpha - 1.061\beta + 0.26665\gamma}{0.6366 + \beta\gamma + 1.061\alpha\beta}\right) \tag{2-107}$$

$$\alpha = \frac{C_v}{R} - 1.5 \qquad \beta = 0.7862 - 0.7109\omega + 1.3168\omega^2$$

$$\gamma = 2.0 + 10.5\,T_r^2 \tag{2-108}$$

***Example*** Estimate the low-pressure thermal conductivity of naphthalene vapor at 500 K.

*Required properties from the DIPPR 801 database:*

$T_c = 748.4$ K  $M = 128.17$ g/mol  $\omega = 0.30203$

$\eta(500\text{ K}) = 1.0173 \times 10^{-5}$ Pa·s

$C_v = C_p^o - R = (219.82 - 8.314)$ J/(mol·K) $= 211.51$ J/(mol·K)

*Auxiliary quantities [Eqs. (2-107) and (2-108)]:*

$T_r = 500/748.4 = 0.6681$  $R/C_v = (8.314)/(211.51) = 0.0393$

$\gamma = 2.0 + (10.5)(0.6681)^2 = 6.6866$  $\alpha = (0.0393)^{-1} - 1.5 = 23.9388$

$\beta = 0.7862 - (0.7109)(0.30203) + (1.3168)(0.30203)^2 = 0.6916$

$$\Psi = 1 + (23.9388)\left[\frac{0.215 + 0.28288\,(23.9388) - 1.061(0.6916) + 0.26665(6.6866)}{0.6366 + 0.6916\,(6.6866) + 1.061(23.9388)\,(0.6916)}\right] = 9.4273$$

*From Eq. (2-106):*

$$k = (3.75)\,(9.4273)\left[\frac{(1.1408\times10^{-5}\ \text{Pa}\cdot\text{s})\left(8.314\ \frac{\text{J}}{\text{mol}\cdot\text{K}}\right)}{128.17\ \frac{\text{g}}{\text{mol}}}\right] = 23.33\ \frac{\text{mW}}{\text{m}\cdot\text{K}}$$

The estimated value is 1.0 percent above the DIPPR 801 value of 23.09 mW/(m·K).

**Liquids** For hydrocarbons at low to moderate pressures, a modification of the Pachaiyappan method should be used. For nonhydrocarbons, the Baroncini method provides accurate liquid thermal conductivity estimates for compounds clearly belonging to one of the chemical families specified below. Otherwise, the Missenard method is recommended as a general method for estimating thermal conductivity of pure liquids at ambient pressure.

***Recommended Method*** Modified Pachaiyappan.

*Reference:* Pachaiyappan, V., S. H. Ibrahim, and N. R. Kuloor, *Chem. Eng.* **74**(4) (1967): 140; *API Technical Databook,* 10th ed., chap. 12, 2017.

*Classification:* Empirical correlation.

*Expected uncertainty:* 10 percent.

*Applicability:* Hydrocarbons only; low to moderate pressures.

*Input data: M*, $T_b$, and $T_c$.

*Description:*

$$\frac{k}{\text{W}\cdot\text{m}^{-1}\text{K}^{-1}} = \frac{C\left(\frac{M}{\text{g}\cdot\text{mol}^{-1}}\right)^m}{\left(\frac{V_{293}}{\text{cm}^3\cdot\text{mol}^{-1}}\right)}\left[\frac{3 + 20(1 - T_r)^{2/3}}{3 + 20(1 - T_{r,293})^{2/3}}\right] \tag{2-109}$$

where $M$ is molecular weight, $V_{293}$ is the molar volume at 293.15 K, $T_r$ is the reduced temperature, $T_{r,293} = (293.15\text{ K})/(T_c)$ and the correlation parameters $C$ and $m$ are obtained from the table below:

| Classification | $C$ | $m$ |
|---|---|---|
| Unbranched, straight-chain hydrocarbon | 0.1811 | 1.001 |
| All branched, cyclic and aromatic hydrocarbons | 0.4407 | 0.7717 |

***Example*** Estimate the thermal conductivity of liquid *n*-butylbenzene at low pressure and 333.15 K.

*Required properties from DIPPR 801 database:*

$M = 134.218$ g/mol  $T_c = 660.5$ K  $V_{293} = 162.01$ cm$^3$/mol

*Auxiliary properties:*

$T_r = (333.15\text{ K})/(660.5\text{ K}) = 0.5044$  $T_{r293} = (293.15\text{ K})/(660.5\text{ K}) = 0.4438$

Since this is an aromatic hydrocarbon,

$C = 0.4407$ and $m = 0.7717$ ( from the above table)

*From Eq. (2-109):*

$$\frac{k}{(\text{W}\cdot\text{m}^{-1}\text{K}^{-1})} = \frac{(0.4407)(134.218)^{0.7717}}{162.01}\left[\frac{3 + 20(1 - 0.5044)^{2/3}}{3 + 20(1 - 0.4438)^{2/3}}\right] = 0.112$$

The estimated value is 5 percent below the experimental value of 0.118 W/(m·K) reported by Rastorguev and Pugach [Rastorguev, Yu. L., and V. V. Pugach, *Izv. Vyssh. Uchebn. Zaved., Neft Gaz*, **13** (1970): 69].

***Recommended Method 1*** Baroncini method.

*Reference:* Baroncini, C., F. DiFilippo, G. Latini, and M. Pacetti, *Int. J. Thermophys.*, **2** (1981): 21.

*Classification:* Empirical correlation.

*Expected uncertainty:* 10 percent.

*Applicability:* Particularly accurate for the following families: acetates, aliphatic ethers, halogenated compounds, dicarboxylic acids, ketones, aliphatic alcohols, aliphatic acids, propionates and butyrates, and unsaturated aliphatic esters.

*Input data:* $M$, $T_b$, and $T_c$.

*Description:*

$$\frac{k}{\mathrm{W/(m\cdot K)}} = A\left(\frac{T_b}{\mathrm{K}}\right)^{\alpha}\left(\frac{M}{\mathrm{g/mol}}\right)^{-\beta}\left(\frac{T_c}{\mathrm{K}}\right)^{-\gamma}\frac{(1-T_r)^{0.38}}{T_r^{1/6}} \tag{2-110}$$

where $A$, $\alpha$, $\beta$, and $\gamma$ are obtained from Table 2-176.

***Example*** Estimate the thermal conductivity of liquid *p*-cresol at 400 K.

*Required properties from DIPPR 801 database:*

$M = 108.1378$ g/mol $\quad T_c = 704.65$ K $\quad T_b = 475.133$ K

*Auxiliary properties:*

$$T_r = T/T_c = (400\ \mathrm{K})/(704.65\ \mathrm{K}) = 0.5677$$

*From Table 2-176 for alcohols:*

$$A = 0.00339 \quad \alpha = 1.2 \quad \beta = \frac{1}{2} \quad \gamma = 0.167$$

*From Eq. (2-110):*

$$\frac{k}{\mathrm{W/(m\cdot K)}} = (0.00339)(475.13)^{1.2}(108.1378)^{-1/2}(704.65)^{-0.167}\frac{(1-0.5677)^{0.38}}{0.5677^{1/6}} = 0.142$$

The estimated value is 7.6 percent higher than the DIPPR 801 value of 0.132 W/(m · K).

***Recommended Method 2*** Missenard method.

*Reference:* Missenard, A., *Comptes Rendus*, **260** (1965): 5521.

*Classification:* Corresponding states.

*Expected uncertainty:* 20 percent.

*Applicability:* Organic compounds; nonassociating.

*Input data:* $T_c$, $n_A$ (number of atoms in molecule), $\rho_{273}$ (liquid density at 273.15 K), $T_b$, $M$, $C_{p,273}$ (liquid heat capacity at 273.15 K).

*Description:*

$$\frac{k_{273}}{\mathrm{mW/(m\cdot K)}} = \left(\frac{8.4}{N_A^{1/4}}\right)\left(\frac{T_b}{\mathrm{K}}\right)^{1/2}\left(\frac{\rho_{273}}{\mathrm{g/m^3}}\right)^{1/2}\left(\frac{M}{\mathrm{g/mol}}\right)^{-1/2}\left[\frac{C_{p,273}}{\mathrm{J/(mol\cdot K)}}\right] \tag{2-111}$$

$$k = \frac{k_{273}[3+20(1-T_r)^{2/3}]}{3+20(1-T_{r,273})^{2/3}} \tag{2-112}$$

where $T_{r,273} = (273\ \mathrm{K})/T_c$.

**TABLE 2-176 Correlation Parameters for Baroncini et al. Method* for Estimation of Thermal Conductivity**

| Family | $A$ | $\alpha$ | $\beta$ | $\gamma$ |
|---|---|---|---|---|
| Saturated hydrocarbons | 0.00350 | 1.2 | 0.5 | 0.167 |
| Olefins | 0.0361 | 1.2 | 1 | 0.167 |
| Cycloparaffins | 0.0310 | 1.2 | 1 | 0.167 |
| Aromatics | 0.0346 | 1.2 | 1 | 0.167 |
| Alcohols | 0.00339 | 1.2 | 0.5 | 0.167 |
| Organic acids | 0.00319 | 1.2 | 0.5 | 0.167 |
| Ketones | 0.00383 | 1.2 | 0.5 | 0.167 |
| Esters | 0.0415 | 1.2 | 1 | 0.167 |

| Refrigerants | | | | |
| R20, R21, R22, R23 | 0.562 | 0 | 0.5 | −0.167 |
| Others | 0.494 | 0 | 0.5 | −0.167 |

*Baroncini, C., et al., *Int. J. Thermophys.*, **2** (1981): 21.

***Example*** Estimate the thermal conductivity of *m*-xylene at 350 K.

*Required properties from DIPPR 801 database:*

$T_c = 617$ K $\quad n_A = 18$ $\quad \rho_{273} = 7.6812$ kmol/m$^3$

$T_b = 412.27$ K $\quad M = 106.165$ kg/kmol $\quad C_{p,273} = 200.64$ kJ/(kmol · K)

*Auxiliary properties:*

$$T_r = 350/617 = 0.5673 \quad T_{br} = 412.27/617 = 0.6682$$
$$T_{r,273} = 273/617 = 0.4425$$

*From Eq. (2-111):*

$$\frac{k_{273}}{\mathrm{mW/(m\cdot K)}} = (8.4)(412.27)^{1/2}(0.007681)^{1/2}(106.165)^{-1/2}(200.64)(18)^{-0.25} = 141.3$$

*From Eq. (2-112):*

$$k = \frac{k_{273}[3+20(1-T_r)^{2/3}]}{3+20(1-T_{r,273})^{2/3}} = \frac{\left(141.3\dfrac{\mathrm{mW}}{\mathrm{m\cdot K}}\right)[3+20(1-0.5673)^{2/3}]}{3+20(1-0.4425)^{2/3}} = 123.3\frac{\mathrm{mW}}{\mathrm{m\cdot K}}$$

The estimated value is 4.5 percent above the DIPPR 801 value of 118.0 mW/(m·K).

**Liquid Mixtures** The thermal conductivity of liquid mixtures generally shows a modest negative deviation from a linear mass-fraction average of the pure-component values. Although more complex methods with some improved accuracy are available, two simple methods are recommended here that require very little additional information. The first method applies only to binary mixtures while the second can be used for multiple components.

***Recommended Method*** Filippov correlation.

*References:* Filippov, L. P., *Vest. Mosk. Univ., Ser. Fiz. Mat. Estestv. Nauk*, **10** (1955): 67; Filippov, L. P., and N. S. Novoselova, Sugden, *Vest. Mosk. Univ., Ser. Fiz. Mat. Estestv. Nauk*, **10** (1955): 37.

*Classification:* Empirical correlation.

*Expected uncertainty:* 4 to 8 percent.

*Applicability:* Binary liquid mixtures.

*Input data:* Pure-component thermal conductivities $k_i$ at mixture conditions; $w_i$.

*Description:* The mixture thermal conductivity is calculated from the pure-component values using

$$k = w_1k_1 + w_2k_2 - 0.72w_1w_2|k_2 - k_1| \tag{2-113}$$

where $w_i$ is the mass fraction of pure fluid $i$ and $k_i$ is the thermal conductivity of pure component $i$ at the mixture temperature.

***Recommended Method*** Li correlation.

*References:* Li, C. C., *AIChE J.*, **22** (1976): 927.

*Classification:* Empirical correlation.

*Expected uncertainty:* 4 to 8 percent.

*Applicability:* Liquid mixtures.

*Input data:* Pure-component thermal conductivities $k_i$ at mixture conditions; $\rho_{L,i}$

*Description:* The mixture thermal conductivity is correlated as a function of the mixture volume fractions $\phi_i$:

$$k = \sum_{i=1}^{C}\sum_{j=1}^{C}\phi_i\phi_j\frac{2k_ik_j}{k_i+k_j} \tag{2-114}$$

$$\text{where } \phi_i = \frac{x_i\rho_{L,i}^{-1}}{\sum_{j=1}^{C}x_j\rho_{L,j}^{-1}}$$

***Example*** Estimate the thermal conductivity of a mixture containing 30.2 mol% diethyl ether(1) and 69.8 mol% methanol(2) at 273.15 K and 0.1 MPa, using the Filippov and Li correlations.

*Auxiliary data:* The pure-component thermal conductivities and molar densities at 273.15 K recommended in the DIPPR 801 database are

$k_1 = 0.1383$ W/(m · K) $\quad \rho_1 = 9.9335$ kmol/m$^3$ $\quad M_1 = 74.1216$ kg/kmol

$k_2 = 0.2069$ W/(m · K) $\quad \rho_2 = 25.371$ kmol/m$^3$ $\quad M_2 = 32.0419$ kg/kmol

The mass fractions corresponding to the mole fractions given above are

$$w_1 = 0.5 \quad w_2 = 0.5$$

The volume fractions are

$$\phi_1 = \frac{(0.302)(9.9335)^{-1}}{(0.302)(9.9335)^{-1} + (0.698)(25.371)^{-1}} = 0.525 \qquad \phi_2 = 0.475$$

*Calculation using Eq. (2-113):*

$$k = [(0.5)(0.1383) + (0.5)(0.2069) - (0.72)(0.5)(0.5)|0.2069 - 0.1383|]\frac{\text{W}}{\text{m}\cdot\text{K}}$$
$$= 0.160 \text{ W/(m}\cdot\text{K)}$$

*Calculation using Eq. (2-114):*

$$k = \left[(0.525)^2(0.1383) + 2\cdot\frac{(0.525)(0.475)(2)(0.1383)(0.2069)}{0.1383 + 0.2069} + (0.475)^2(0.2069)\right]\frac{\text{W}}{\text{m}\cdot\text{K}}$$
$$= 0.167 \text{ W/(m}\cdot\text{K)}$$

The Filippov value is 7.5 percent lower than the experimental value of 0.173 W/(m·K) [Jamieson, D. T., and B. K. Hastings, *Thermal Conductivity*, *Proceedings of the Eighth Conference*, C. Y. Ho and R. E. Taylor, eds., Plenum Press, New York, 1969]; the Li value is 3.5 percent lower than the experimental value.

## SURFACE TENSION

The surface at a vapor-liquid interface is in tension due to the difference in attractive forces experienced by molecules at the interface between the dense liquid phase and the low-density gas phase. This causes the liquid to contract to minimize the surface area. *Surface tension* is defined as the force in the surface plane per unit length. Jasper [Jasper, J. J., *J. Phys. Chem. Ref. Data*, **1** (1972): 841] has made a critical evaluation of experimental surface tension data for approximately 2200 pure chemicals and correlated surface tension σ (mN/m = dyn/cm) with temperature as

$$\sigma = A - BT \tag{2-115}$$

Jasper's evaluation also includes values of $A$ and $B$ for most of the tabulated chemicals. Surface tension decreases with increasing temperature and increasing pressure.

**Pure Liquids** An approach suggested by Macleod [Macleod, D. B., *Trans. Faraday Soc.*, **19** (1923): 38] and modified by Sugden [Sugden, S. J., *Chem. Soc.*, **125** (1924): 32] relates σ to the liquid and vapor *molar* densities and a temperature-independent parameter called the Parachor **P**

$$\frac{\sigma}{\text{mN/m}} = \left[\mathbf{P}\cdot\left(\frac{\rho_L - \rho_v}{10^3\text{kmol/m}^3}\right)\right]^4 \tag{2-116}$$

where $\rho_L$ and $\rho_V$ are the saturated molar liquid and vapor densities, respectively. At low temperatures, where $\rho_L >> \rho_V$, the vapor density can be neglected, but at higher temperatures the density of both phases must be calculated. The surface tension is zero at the critical point where $\rho_L = \rho_V$. Quayle [Quayle, O. R., *Chem. Rev.*, **53** (1953): 439] proposed a group contribution method for estimating **P** that has been improved in recent years by Knotts et al. [Knotts, T. A., et. al., *J. Chem. Eng. Data*, **46** (2001): 1007]. This method using **P** is recommended when groups are available; otherwise, the Brock-Bird [Brock, J. R., and R. B. Bird, *AIChE J.*, **1** (1955): 174] corresponding-states method as modified by Miller [Miller, D. G., *Ind. Eng. Chem. Fundam.*, **2** (1963): 78] may be used to estimate surface tension for compounds that are not strongly polar or associating.

***Recommended Method 1*** Parachor method.

*References:* Macleod, D. B., *Trans. Faraday Soc.*, **19** (1923): 38; Sugden, S. J., *Chem. Soc.*, **125** (1924): 32; Knotts, T. A., W. V. Wilding, J. L. Oscarson, and R. L. Rowley, *J. Chem. Eng. Data*, **46** (2001): 1007.

*Classification:* Group contributions and QSPR.

*Expected uncertainty:* 4 percent.

*Applicability:* Organic compounds for which group values are available.

*Input data:* $\rho_L$, molecular structure, and Table 2-177.

*Description:* Equation (2-116) is used with **P** calculated from

$$\mathbf{P} = \sum_{i=1}^{N} n_i \,\Delta\mathbf{P}_i \tag{2-117}$$

Group values for the Parachor are given in Table 2-177.

***Example*** Estimate the surface tension of ethylacetylene at 237.45 K.

*Structure:*

| Group | $n_i$ | $\Delta P_i$ | $n_i \Delta P_i$ |
|---|---|---|---|
| ≡CH | 1 | 43.64 | 43.64 |
| ≡C— | 1 | 28.64 | 28.64 |
| >$CH_2$ ($n$ = 1–11) | 1 | 39.92 | 39.92 |
| $CH_3$ | 1 | 55.25 | 55.25 |
| | | Total | 167.45 |

*Required properties:* The DIPPR 801 database gives $\rho_L = 13.2573$ kmol/m³ at 237.45 K.

*Calculation using Eq. (2-116):*

$$\sigma = \left[(167.45)\left(\frac{13.2573}{1000}\right)\right]^4 \frac{\text{mN}}{\text{m}} = 0.02429\frac{\text{N}}{\text{m}}$$

The estimated value is 0.9 percent above the DIPPR 801 recommended value of 0.02407 N/m.

***Recommended Method 2*** Brock-Bird method.

*Reference:* Brock, J. R., and R. B. Bird, *AIChE J.*, **1** (1955): 174; Miller, D. G., *Ind. Eng. Chem. Fundam.*, **2** (1963): 78.

*Classification:* Corresponding states.

*Expected uncertainty:* 5 percent.

*Applicability:* Nonpolar and moderately polar organic compounds.

*Input data:* $T_c$, $P_c$, and $T_b$.

*Description:*

$$\frac{\sigma}{\text{mN/m}} = (5.553\times10^{-5})\left(\frac{P_c}{\text{Pa}}\right)^{2/3}\left(\frac{T_c}{\text{K}}\right)^{1/3} F(1-T_r)^{11/9} \tag{2-118}$$

where

$$F = \frac{T_{br}[\ln(P_c/\text{Pa}) - 11.5261]}{1 - T_{br}} - 1.3281 \tag{2-119}$$

***Example*** Estimate the surface tension for ethyl mercaptan at 303.15 K.

*Required properties from DIPPR 801:*

$T_c = 499.15$ K $\qquad P_c = 5.49 \times 10^6$ Pa $\qquad T_b = 308.15$ K

*Supporting quantities:*

$T_r = (303.15 \text{ K})/(499.15 \text{ K}) = 0.6073$

$T_{br} = (308.15 \text{ K})/(499.15 \text{ K}) = 0.6173$

$F = \{0.6173[\ln(5.49\times10^6) - 11.5261]/(1 - 0.6173)\} - 1.3281 = 5.113$ [from Eq. (2-119)]

*From Eq. (2-118):*

$$\sigma = (5.553\times10^{-5})(5.49\times10^6)^{2/3}(499.15)^{1/3}(5.113)(1-0.6073)^{11/9} \text{ mN/m}$$
$$= 22.36 \text{ mN/m}$$

The estimated value is 1.4 percent lower than the DIPPR 801 value of 22.68 mN/m.

**Liquid Mixtures** Compositions at the liquid-vapor interface are not the same as in the bulk liquid, and so simple (bulk) composition-weighted averages of the pure-fluid values do not provide quantitative estimates of the surface tension at the vapor-liquid interface of a mixture. The behavior of aqueous mixtures is more difficult to correlate and estimate than that of nonpolar mixtures because small amounts of organic material can have a pronounced effect upon the surface concentrations and the resultant surface tension. These effects are usually modeled with thermodynamic methods that account for the activity coefficients. For example, a UNIFAC method [Suarez, J. T., C. Torres-Marchal, and P. Rasmussen, *Chem. Eng. Sci.*, **44** (1989): 782] is recommended and illustrated in [PGL5]. For nonaqueous systems the extension of the Parachor method, used above for pure fluids, is a simple and reasonably effective method for estimating σ for mixtures.

***Recommended Method*** Parachor correlation.

*Reference:* Hugill, J. A., and A. J. van Welsenes, *Fluid Phase Equilib.*, **29** (1986): 383; Macleod, D. B., *Trans. Faraday Soc.*, **19** (1923): 38; Sugden, S. J., *Chem. Soc.*, **125** (1924).

*Classification:* Corresponding states.

*Expected uncertainty:* 3 to 10 percent.

*Applicability:* Nonaqueous mixtures.

**TABLE 2-177 Knotts* Group Contributions for the Parachor in Estimating Surface Tension**

*Knotts, T. A., et al., *J. Chem. Eng. Data*, **46** (2001): 1007.

*Input data:* Liquid and vapor ρ at mixture $T$; Parachors of pure components; $x_i$.

*Description:*

$$\frac{\sigma_m}{\text{mN/m}} = \left( \mathbf{P}_{L,m} \frac{\rho_{L,m}}{10^3 \text{kmol/m}^3} - \mathbf{P}_{v,m} \frac{\rho_{V,m}}{10^3 \text{kmol/m}^3} \right)^4 \qquad (2\text{-}120)$$

where $\sigma_m$ = surface tension of the mixture
$\mathbf{P}_{L,m}$, $\mathbf{P}_{V,m}$ = Parachor of liquid and vapor mixtures, respectively
$\rho_{L,m}$, $\rho_{V,m}$ = mixture molar density of liquid and vapor, respectively

The following definitions are used for the liquid and vapor mixture Parachors:

$$\mathbf{P}_{L,m} = \frac{1}{2} \sum_{i=1}^{C} \sum_{j=1}^{C} x_i x_j (\mathbf{P}_i + \mathbf{P}_j) \qquad \mathbf{P}_{V,m} = \frac{1}{2} \sum_{i=1}^{C} \sum_{j=1}^{C} y_i y_j (\mathbf{P}_i + \mathbf{P}_j) \qquad (2\text{-}121)$$

where $x_i$ is the mole fraction of component $i$ in the liquid and $y_i$ is the mole fraction of component $i$ in the vapor.

Note that $\rho_V$ is generally very small compared to $\rho_L$ at temperatures substantially lower than $T_c$ and can often be neglected.

***Example*** Estimate the surface tension for a 16.06 mol% *n*-pentane(1) + 83.94 mol% dichloromethane(2) mixture at 298.15 K.

*Required properties from DIPPR 801:*

| | **P** | $\rho_L$/(kmol·m$^{-3}$) at 298.15 K |
|---|---|---|
| *n*-Pentane | 231.1 | 8.6173 |
| Dichloromethane | 146.6 | 15.5211 |

*Mixture Parachor from Eq. (2-121) and mixture density:*

$$\mathbf{P}_{L,m} = (0.1606)^2(231.1) + (0.1606)(0.8394)(231.1 + 146.6) + (0.8394)^2(146.6) = 160.17$$

$$\rho_{L,m} = \left( \sum_{i=1}^{C} \frac{x_i}{\rho_i} \right)^{-1} = \left( \frac{0.1606}{8.6173} + \frac{0.8394}{15.5211} \right)^{-1} \frac{\text{kmol}}{\text{m}^3} = 13.752 \frac{\text{kmol}}{\text{m}^3}$$

*Calculation using Eq. (2-120):* Because the temperature is low, the density of the vapor can be neglected, and

$$\frac{\sigma_m}{\text{mN/m}} = [(160.17)(0.013752)]^4 = 23.54\,\frac{\text{mN}}{\text{m}}$$

The estimated value is 2.9 percent below the experimental value of 24.24 mN/m reported by De Soria [De Soria, M. L. G., et al., *J. Colloid Interface Sci.,* **103** (1985): 354].

## FLAMMABILITY PROPERTIES

**Flash Point** The flash point is the lowest temperature at which a liquid gives off sufficient vapor to form an ignitable mixture with air near the surface of the liquid or within the vessel used. ASTM test methods include procedures using a closed-cup apparatus (ASTM D 56, ASTM D 93, and ASTM D 3828), which is preferred, and an open-cup apparatus (ASTM D 92 and ASTM D 1310). Closed-cup values are typically lower than open-cup values. Estimation methods cannot take into account the apparatus and procedural influences on the observed flash point.

***Recommended Method*** Leslie-Geniesse method.

*Reference:* Leslie, E. H., and J. C. Geniesse, *International Critical Tables,* vol. 2, McGraw-Hill, New York, 1927, p. 161.

*Classification:* GC (element contributions).

*Expected uncertainty:* ~4 K or about 1.5 percent.

*Applicability:* Organic compounds.

*Input data:* Chemical structure and vapor pressure correlation.

*Description:* The flash point $T_{FP}$ is obtained from the moles of oxygen required for stoichiometric combustion β, by back-solving from the vapor pressure correlation using

$$\frac{P^*(T_{FP})}{\text{atm}} = \frac{1}{8\beta} \tag{2-122}$$

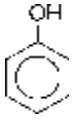
where $P^*$ = vapor pressure at the flash point

$$\beta = N_C + N_{Si} + N_S + \frac{N_H - N_X - 2N_O}{4} \tag{2-123}$$

$N_C$, $N_{Si}$, $N_S$, $N_H$, $N_X$, $N_O$ = number of carbon, silicon, sulfur, hydrogen, halogen, and oxygen atoms in the molecule, respectively

***Example*** Estimate the flash point of phenol.

*Structure:*



*Atomic contributions:*

| Atom type | Number |
|---|---|
| C | 6 |
| H | 6 |
| O | 1 |

*From Eq. (2-123),* $\beta = 6 + (6 - 2{\cdot}1)/4 = 7$

*The DIPPR 801 correlation for the vapor pressure of phenol is*

$$\frac{P^*}{\text{Pa}} = \exp\left[95.444 - \frac{10{,}113\ \text{K}}{T} - 10.09\ \ln\left(\frac{T}{\text{K}}\right) + 6.7603\times10^{-18}\left(\frac{T}{\text{K}}\right)^6\right]$$

When this expression is used in Eq. (2-122) and solved for temperature, one obtains $T_{FP}$ = 350.84 K, which is 0.4 percent below the DIPRR recommended value of 352.15 K.

**Flammability Limits** The lower flammability limit (LFL) is the equilibrium-mixture boundary-line volume percent of vapor or gas in air which if ignited will just propagate a flame away from the ignition source. Similarly, the upper flammability limit (UFL) is the upper volume percent boundary at which a flame can propagate in an ignited fuel/air equilibrium mixture. Each of these limits has a temperature at which the corresponding volumetric percent is reached. The lower flammability limit temperature corresponds approximately to the flash point, but since the flash point is determined with downward flame propagation and nonuniform mixtures and the lower flammability temperature is determined with upward flame propagation and uniform vapor mixtures, the measured lower flammability temperature is generally slightly lower than the flash point.

***Recommended Method*** Rowley method.

*Reference:* Rowley, J. R., R. L. Rowley, and W. V. Wilding, *J. Hazard. Materials*, **186** (2011): 551; Rowley, J. R., "Flammability Limits, Flash Points, and Their Consanguinity: Critical Analysis, Experimental Exploration, and Prediction," Ph.D. Dissertation, Brigham Young University, 2010.

*Classification:* GC and extended theory.

*Expected uncertainty:* 10 percent for the lower limit; 25 percent for the upper limit.

*Applicability:* Organic compounds.

*Input data:* Group contributions from Tables 2-178, $\Delta H_f^o$, and the thermal properties (ideal gas heat of formation and average isobaric heat capacity) of the combustion products. These latter quantities are given in Table 2-179. A vapor pressure correlation is also required to obtain the corresponding flammability limit temperature.

*Description:* A GC method is used to obtain the adiabatic flame temperature ($T_{ad}$) of a lower-limit fuel-air mixture using the $\Delta T_{ad,j}$ contributions shown in Table 2-178:

$$T_{ad} = \frac{\sum_j n_j \cdot \Delta T_{ad,j}}{N} \tag{2-124}$$

where $N$ is the total number of groups in the molecule. The ideal gas enthalpies $H_i$ of the combustion products and oxygen at $T_{ad}$ are then calculated from the ideal gas enthalpies of formation at 298 K and the average isobaric heat capacities (given in Table 2-179) with Eq. (2-125):

$$\frac{H_i(T_{ad})}{\text{kJ/mol}} = \frac{\Delta H_{f,i}^o}{\text{kJ/mol}} + \frac{C_{p,i}}{(\text{kJ/mol}\cdot\text{K})}(T_{ad} - 298)\text{K} \tag{2-125}$$

The lower flammability limit in volume percent is then calculated from

$$\text{LFL} = \frac{100\%}{1+\nu} \quad \nu = \frac{\Delta H_{f,\text{fuel}}^o - \sum_{\text{products}} n_i H_i(T_{ad}) + \beta H_{O_2}(T_{ad})}{C_{p,\text{air}}(T_{ad} - 298)\,\text{K}} \tag{2-126}$$

where β is defined in Eq. (2-123).

The upper flammability limit in volume percent is obtained from the UFL group values given in Table 2-178 and

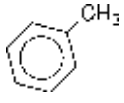
$$\frac{\text{UFL}}{\%} = \left[4.30 C_{st}^{0.72} + \frac{\sum_j n_j \cdot \text{UFL}_j}{N}\right] \tag{2-127}$$

where $C_{st}$ is the fuel concentration required for stoichiometric combustion given by

$$C_{st} = \frac{100}{1 + 4.773\beta} \tag{2-128}$$

***Example*** Estimate the lower and upper flammability limits of toluene.

*Structure:*



*Group contributions:*

| Group | $n_j$ | $\Delta T_{ad}$ | $\text{UFL}_j$ |
|---|---|---|---|
| $CH_3$—c | 1 | 1862.04 | −4.49 |
| c— | 1 | 1719.69 | 5.50 |
| c—H | 5 | 1731.92 | −1.25 |

*Auxiliary calculations:*

$T_{ad}$ = [1862.04 + 1719.69 + (5)(1731.92)]/7 = 1748.8

β = 7 + 8/4 = 9

**TABLE 2-178 Group Contributions for Quantities Used to Estimate Flammability Limits by Rowley et al.* Method for Organic Compounds (special notation: lower case indicates aromatic atom; # = triple bond; R = ring)**

*Calculation of $H(T_{ad})$ from Eq. (2-125) and Table 2-179:*

| Species | $H°$(298 K)/(kJ/mol) | $C_p$/[kJ/(mol·K)] | $H(T_{ad})$/(kJ/mol) |
|---|---|---|---|
| Toluene | 50.17 | — | — |
| $CO_2$ | −393.51 | 0.0372433 | −339.48 |
| $H_2O$ | −241.81 | 0.0335780 | −193.10 |
| $O_2$ | 0 | 0.0293468 | 42.58 |
| Air | 0 | 0.0289937 | — |

*From Eq. (2-126) and the stoichiometry of the combustion reaction,* $C_7H_8 + 9O_2 = 7CO_2 + 4H_2O$:

$$\nu = \left[\frac{50.17 - [(7)(-339.48) + (4)(-193.10)] + (9)(42.58)}{(0.0289937)(1749 - 298)}\right] = 85.148$$

**TABLE 2-179 Ideal Gas Enthalpies of Formation and Average Heat Capacities of Combustion Gases for Use in Eq. (2-125)**

| Species | $H°$/(kJ/mol) | $C_p$/[J/(mol·K)] |
|---|---|---|
| Air | 0 | 28.9937 |
| $O_2$ | 0 | 29.3468 |
| $N_2$ | 0 | 29.1260 |
| $CO_2$ | −393.51 | 37.2433 |
| $H_2O$ | −241.81 | 33.5780 |
| $SO_2$ | −296.84 | 39.8980 |
| $SiO_2$ | −305.43 | 44.0254 |
| HF | −273.30 | 29.1361 |
| HCl | −92.31 | 29.1436 |
| HBr | −36.29 | 29.1327 |
| HI | −26.50 | 29.1583 |

$$\text{LFL} = \frac{100\%}{1 + 85.148} = 1.16\%$$

*The UFL is found from Eqs. (2-127) and (2-128):*

$$\text{UFL} = (4.30)\left[\frac{100}{1 + (4.773)(9)}\right]^{0.72} + \frac{-4.49 + 5.50 + (5)(-1.25)}{7} = 7.02\%$$

These values agree well with the DIPPR 801 recommended values of 1.2 and 7.1 percent, respectively.

Flammability limit temperatures are found by determining the temperature at which the vapor pressure equals the partial pressure corresponding to the LFL or UFL. The vapor pressure correlation for toluene from DIPPR 801 is

$$\frac{P^*}{\text{Pa}} = \exp\left[76.945 - \frac{6729.8\ \text{K}}{T} - 8.179\ln\left(\frac{T}{\text{K}}\right) + 5.3017 \times 10^{-6}\left(\frac{T}{\text{K}}\right)^2\right]$$

*Back-solving for T using the partial pressures of 0.0116 atm for LFL and 0.0702 atm for UFL gives*

$$T_{\text{LFL}} = 277\ \text{K and } T_{\text{UFL}} = 311\ \text{K}$$

**Autoignition Temperature** The autoignition temperature (AIT) is the minimum temperature for a substance to initiate self-combustion in air in the absence of an ignition source. Methods to estimate AIT are in general rather approximate. The method illustrated here may provide reasonable estimates, but significant errors can also result. Estimated values should not be assumed to be reliable for design and safety purposes.

**TABLE 2-180 Group Contributions for Pintar* Autoignition Temperature Method for Organic Compounds**

| Group | $b_i$ | Group | $b_i$ | Group | $b_i$ |
|---|---|---|---|---|---|

*Pintar, A. J., *Estimation of Autoignition Temperature*, Technical Support Document DIPPR Project 912, Michigan Technological University, Houghton, 1996.

†Does not include contribution of atoms attached to silicon.

***Recommended Method*** Pintar method.

*Reference:* Pintar, A. J., *Estimation of Autoignition Temperature,* Technical Support Document DIPPR Project 912, Michigan Technological University, Houghton, 1996.

*Classification:* Group contributions.

*Expected uncertainty:* 25 percent.

*Applicability:* Organic compounds.

*Input data:* Group contributions from Table 2-180.

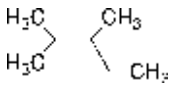
*Description:* A simple GC method with first-order contributions is given by

$$\mathrm{AIT} = \sum_{i=1}^{N} n_i b_i \qquad (2\text{-}129)$$

where $n_i$ is the number of groups of type $i$ in the molecule and $b_i$ is the contribution of group $i$ to the autoignition temperature. A more accurate but somewhat more complicated logarithmic GC method was also developed by Pintar in the same reference cited here.

***Example*** Estimate the autoignition temperature of 2,3-dimethylpentane.

*Structure and group information:*



| Group | $n_i$ | $b_i$ |
|---|---|---|
| —$CH_3$ | 4 | 301.91 |
| >$CH_2$ | 1 | −10.86 |
| >CH— | 2 | −275.17 |

*Calculation using Eq. (2-129):*

$$\mathrm{AIT} = 4(301.91) - 10.86 + 2(-275.17) = 646.4\ \mathrm{K}$$

The estimated value is 6.3 percent above the DIPPR 801 recommended value of 608.15 K.

## MATHEMATICS

### GENERAL

The basic problems of the sciences and engineering fall broadly into three categories:

1. *Steady-state problems.* In such problems the configuration of the system is to be determined. This solution does not change with time but continues indefinitely in the same pattern, hence the name *steady state*. Typical chemical engineering examples include steady temperature distributions in heat conduction, equilibrium in chemical reactions, and steady diffusion problems.
2. *Eigenvalue problems.* These are extensions of equilibrium problems in which critical values of certain parameters are to be determined in addition to the corresponding steady-state configurations. The determination of eigenvalues may also arise in propagation problems and stability problems. Typical chemical engineering problems include those in heat transfer and resonance in which certain boundary conditions are prescribed.
3. *Propagation problems.* These problems are concerned with predicting the subsequent behavior of a system from a knowledge of the initial state. For this reason they are often called the *transient* (time-varying) or *unsteady-state* phenomena. Chemical engineering examples include the transient state of chemical reactions (kinetics), the propagation of pressure waves in a fluid, transient behavior of an adsorption column, and the rate of approach to equilibrium of a packed distillation column.

The mathematical treatment of engineering problems involves four basic steps:

1. *Formulation.* This involves the expression of the problem in mathematical language. That translation is based on the appropriate physical laws governing the process.
2. *Solution.* Appropriate mathematical and numerical operations are carried out so that logical deductions may be drawn from the mathematical model.
3. *Interpretation.* This process develops relations between the mathematical results and their meaning in the physical world.
4. *Refinement.* The procedure is recycled to obtain better predictions, as indicated by experimental checks.

Steps 1 and 2 are of primary interest here. The actual details are left to the various subsections, and only general approaches will be discussed.

The formulation step may result in algebraic equations, difference equations, differential equations, integral equations, or combinations of these. In any event these mathematical models usually arise from statements of physical laws such as the laws of mass and energy conservation in the form

$$\text{Input of } x - \text{output of } x + \text{production of } x = \text{accumulation of } x$$

or

$$\text{Rate of input of } x - \text{rate of output of } x + \text{rate of production of } x = \text{rate of accumulation of } x$$

where $x$ = mass, energy, etc. These statements may be abbreviated by the statement

$$\text{Input} - \text{output} + \text{production} = \text{accumulation}$$

Many general laws of the physical universe are expressible by differential equations. Specific phenomena are then singled out from the infinity of solutions of these equations by assigning the individual initial or boundary conditions which characterize the given problem. For steady-state or boundary-value problems (Fig. 3-1), the solution must satisfy the differential equation inside the region and the prescribed conditions on the boundary.

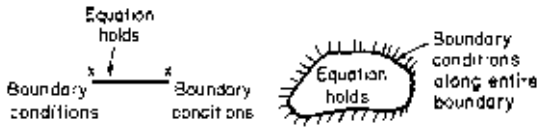

**FIG. 3-1** Boundary conditions.

In mathematical language, the propagation problem is known as an *initial-value problem* (Fig. 3-2). Schematically, the problem is characterized by a differential equation plus an open region in which the equation holds. The solution of the differential equation must satisfy the initial conditions plus any "side" boundary conditions.

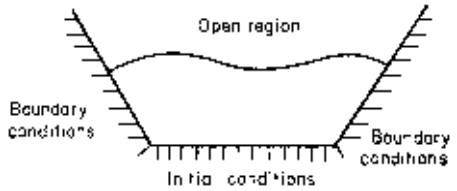

**FIG. 3-2** Propagation problem.

The description of phenomena in a continuous medium such as a gas or a fluid often leads to partial differential equations. In particular, phenomena of "wave" propagation are described by a class of partial differential equations called *hyperbolic*, and these are essentially different in their properties from other classes such as those that describe equilibrium (*elliptic*) or diffusion and heat transfer (*parabolic*). Prototypes are as follows:

1. *Elliptic.* Laplace's equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

Poisson's equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = g(x, y)$$

These do not contain the variable $t$ (time) explicitly; accordingly, their solutions represent equilibrium configurations. Laplace's equation corresponds to a "natural" equilibrium, while Poisson's equation corresponds to an

equilibrium under the influence of $g(x, y)$. Steady heat-transfer and mass-transfer problems are elliptic.

2. *Parabolic.* The heat equation

$$\frac{\partial u}{\partial t}=\frac{\partial^2 u}{\partial x^2}+\frac{\partial^2 u}{\partial y^2}$$

describes unsteady or propagation states of diffusion as well as heat transfer.

3. *Hyperbolic.* The wave equation

$$\frac{\partial^2 u}{\partial t^2}=\frac{\partial^2 u}{\partial x^2}+\frac{\partial^2 u}{\partial y^2}$$

describes wave propagation of all types when the assumption is made that the wave amplitude is small and that interactions are linear.

The solution phase has been characterized in the past by a concentration on methods to obtain analytic solutions to the mathematical equations. These efforts have been most fruitful in the area of linear equations such as those just given. However, many natural phenomena are nonlinear. While there are a few nonlinear problems that can be solved analytically, most cannot. In those cases, numerical methods are used. Due to the widespread availability of software for computers, the engineer has quite good tools available. Numerical methods almost never fail to provide an answer to any particular situation, but they can never furnish a general solution of any problem. The mathematical details outlined here include both analytic and numeric techniques useful in obtaining solutions to problems.

Our discussion to this point has been confined to those areas in which the governing laws are well known. However, in many areas, information on the governing laws is lacking and statistical methods are used. Broadly speaking, statistical methods may be of use whenever conclusions are to be drawn or decisions made on the basis of experimental evidence. Since statistics could be defined as the technology of the scientific method, it is primarily concerned with the first two aspects of the method, namely, the performance of experiments and the drawing of conclusions from experiments. Traditionally the field is divided into two areas:

1. *Design of experiments.* When conclusions are to be drawn or decisions made on the basis of experimental evidence, statistical techniques are most useful when experimental data are subject to errors. First, the design of experiments may be carried out in such a fashion as to avoid some of the sources of experimental error and make the necessary allowances for that portion which is unavoidable. Second, the results can be presented in terms of probability statements which express the reliability of the results. Third, a statistical approach frequently forces a more thorough evaluation of the experimental aims and leads to a more definitive experiment than would otherwise have been performed.

2. *Statistical inference.* The broad problem of statistical inference is to provide measures of the uncertainty of conclusions drawn from experimental data. This area uses the theory of probability, enabling scientists to assess the reliability of their conclusions in terms of probability statements.

Both of these areas, the mathematical and the statistical, are intimately intertwined when applied to any given situation. The methods of one are often combined with those of the other. And both, in order to be successfully used, must result in the numerical answer to a problem, that is, they constitute the means to an end. Increasingly the numerical answer is being obtained from the mathematics with the aid of computers. The mathematical notation is given in Table 3-1.

## MISCELLANEOUS MATHEMATICAL CONSTANTS AND FORMULAS

Numerical values of the constants that follow are approximate to the number of significant digits given.

| | |
|---|---|
| $\pi = 3.1415926536$ | Pi |
| $e = 2.7182818285$ | Napierian (natural) logarithm base |
| $\gamma = 0.5772156649$ | Euler's constant |
| Radian $= 57.2957795131°$ | |

**Integral Exponents (Powers and Roots)** If $m$ and $n$ are positive integers and $a$ and $b$ are numbers or functions, then the following properties hold:

$$a^{-n}=1/a^n \qquad a\neq 0$$
$$(ab)^n=a^n b^n$$
$$(a^n)^m=a^{nm} \qquad a^n a^m=a^{n+m}$$
$$\sqrt[n]{a}=a^{1/n} \quad \text{if} \quad a>0$$
$$a^0=1\,(a\neq 0)$$
$$0^a=0\,(a\neq 0)$$

**TABLE 3-1 Mathematical Signs, Symbols, and Abbreviations**

| | |
|---|---|
| $\mp$ ($\pm$) | plus or minus (minus or plus) |
| : | divided by, ratio sign |
| :: | proportional sign |
| $<$ | less than |
| $\not<$ | not less than |
| $>$ | greater than |
| $\not>$ | not greater than |
| $\cong$ | approximately equals, congruent to |
| $\sim$ | similar to |
| $\eqsim$ | equivalent to |
| $\neq$ | not equal to |
| $\doteq$ | approaches, is approximately equal to |
| $\propto$ | varies as |
| $\infty$ | infinity |
| $\therefore$ | therefore |
| $\cap$ | intersection |
| $\sqrt{\ }$ | square root |
| $\sqrt[3]{\ }$ | cube root |
| $\sqrt[n]{\ }$ | $n$th root |
| $\angle$ | angle |
| $\perp$ | perpendicular to |
| $\parallel$ | parallel to |
| $\lvert x \rvert$ | numerical value of $x$ |
| log (or $\log_{10}$) | common logarithm or Briggsian logarithm |
| ln (or $\log_e$) | natural logarithm or hyperbolic logarithm or Napierian logarithm |
| $e$ | base (2.718) of natural system of logarithms |
| $a°$ | an angle $a$ degrees |
| $a'$ | $a$ prime, an angle $a$ minutes |
| $a''$ | $a$ double prime, an angle $a$ seconds, $a$ second |
| sin | sine |
| cos | cosine |
| tan | tangent |
| cot (or ctn) | cotangent |
| sec | secant |
| csc | cosecant |
| $\sin^{-1}$ | inverse sin, anti-sine, or angle whose sine is |
| sinh | hyperbolic sine |
| cosh | hyperbolic cosine |
| tanh | hyperbolic tangent |
| $\sinh^{-1}$ | anti-hyperbolic sine or angle whose hyperbolic sine is |
| $f(x)$ or $\phi(x)$ | function of $x$ |
| $\Delta x$ | increment of $x$, delta $x$ |
| $\Sigma$ | summation of |
| $dx$ | differential of $x$ |
| $dy/dx$ or $y'$ | derivative of $y$ with respect to $x$ |
| $d^2y/dx^2$ or $y''$ | second derivative of $y$ with respect to $x$ |
| $d^ny/dx^n$ | $n$th derivative of $y$ with respect to $x$ |
| $\partial y/\partial x$ | partial derivative of $y$ with respect to $x$ |
| $\partial^n y/\partial x^n$ | $n$th partial derivative of $y$ with respect to $x$ |
| $\frac{\partial^n z}{\partial x \partial y}$ | $n$th partial derivative with respect to $x$ and $y$ |
| $\int$ | integral of |
| $\int_a^b$ | integral between the limits $a$ and $b$ |
| $\dot{y}$ | first derivative of $y$ with respect to time |
| $\ddot{y}$ | second derivative of $y$ with respect to time |
| $\Delta$ or $\nabla^2$ | laplacian $\left(\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+\frac{\partial^2}{\partial z^2}\right)$ |
| $\delta$ | sign of a variation |
| $\oint$ | sign for integration around a closed path |

**Logarithms**

$$\log ab = \log a + \log b, a > 0, b > 0$$
$$\log a^n = n \log a$$
$$\log (a/b) = \log a - \log b$$
$$\log \sqrt[n]{a} = (1/n) \log a$$

The common logarithm (base 10) is denoted $\log a$ (or $\log_{10} a$ in some texts). The natural logarithm (base $e$) is denoted $\ln a$ (or in some texts $\log_e a$). If the text is ambiguous (perhaps using log $x$ for ln $x$), test the formula by evaluating it.

## ALGEBRAIC INEQUALITIES

**Arithmetic-Geometric Inequality** Let $A_n$ and $G_n$ denote, respectively, the arithmetic and the geometric means of a set of positive numbers $a_1, a_2, \ldots, a_n$. Then $A_n \geq G_n$, that is,

$$\frac{a_1 + a_2 + \cdots + a_n}{n} \geq (a_1 a_2 \cdots a_n)^{1/n}$$

The equality holds only if all the numbers $a_i$ are equal.

**Carleman's Inequality** The arithmetic and geometric means just defined satisfy the inequality

$$\sum_{r=1}^{n} (a_1 a_2 \cdots a_r)^{1/r} \leq neA_n$$

where $e$ is the best possible constant in this inequality.

**Cauchy-Schwarz Inequality** Let $a = (a_1, a_2, \ldots, a_n)$ and $b = (b_1, b_2, \ldots, b_n)$, where the $a_i$ and $b_i$ are real or complex numbers. Then

$$\left| \sum_{k=1}^{n} (a_k \bar{b}_k) \right|^2 \leq \left( \sum_{k=1}^{n} |a_k|^2 \right) \left( \sum_{k=1}^{n} |b_k|^2 \right)$$

The equality holds if, and only if, the vectors $a$ and $b$ are linearly dependent (i.e., one vector is a scalar times the other vector).

**Minkowski's Inequality** Let $a_1, a_2, \ldots, a_n$ and $b_1, b_2, \ldots, b_n$ be any two sets of complex numbers. Then for any real number $p > 1$,

$$\left( \sum_{k=1}^{n} |a_k + b_k|^p \right)^{1/p} \leq \left( \sum_{k=1}^{n} |a_k|^p \right)^{1/p} + \left( \sum_{k=1}^{n} |b_k|^p \right)^{1/p}$$

**Hölder's Inequality** Let $a_1, a_2, \ldots, a_n$ and $b_1, b_2, \ldots, b_n$ be any two sets of complex numbers, and let $p$ and $q$ be positive numbers with $1/p + 1/q = 1$. Then

$$\left| \sum_{k=1}^{n} a_k \bar{b}_k \right| \leq \left( \sum_{k=1}^{n} |a_k|^p \right)^{1/p} \left( \sum_{k=1}^{n} |b_k|^q \right)^{1/q}$$

The equality holds if, and only if, the sequences $|a_1|^p, |a_2|^p, \ldots, |a_n|^p$ and $|b_1|^q, |b_2|^q, \ldots, |b_n|^q$ are proportional and the argument (angle) of the complex numbers $a_k \bar{b}_k$ is independent of $k$. This last condition is of course automatically satisfied if $a_1, \ldots, a_n$ and $b_1, \ldots, b_n$ are positive numbers.

**Lagrange's Inequality** Let $a_1, a_2, \ldots, a_n$ and $b_1, b_2, \ldots, b_n$ be real numbers. Then

$$\left( \sum_{k=1}^{n} a_k b_k \right)^2 = \left( \sum_{k=1}^{n} a_k^2 \right) \left( \sum_{k=1}^{n} b_k^2 \right) - \sum_{1 \leq k \leq j \leq n} (a_k b_j - a_j b_k)^2$$

***Example*** Two chemical engineers, Mary and John, purchase stock in the same company at times $t_1, t_2, \ldots, t_n$, when the price per share is, respectively, $p_1, p_2, \ldots, p_n$. Their methods of investment are different, however: John purchases $x$ shares each time, whereas Mary invests $P$ dollars each time (fractional shares can be purchased). Who is doing better?

While one can argue intuitively that the average cost per share for Mary does not exceed that for John, we illustrate a mathematical proof using inequalities. The average cost per share for John is equal to

$$\frac{\text{Total money invested}}{\text{Number of shares purchased}} = \frac{x \sum_{i=1}^{n} p_i}{nx} = \frac{1}{n} \sum_{i=1}^{n} p_i$$

The average cost per share for Mary is

$$\frac{nP}{\sum_{i=1}^{n} \frac{P}{p_i}} = \frac{n}{\sum_{i=1}^{n} \frac{1}{p_i}}$$

Thus the average cost per share for John is the arithmetic mean of $p_1, p_2, \ldots, p_n$, whereas that for Mary is the harmonic mean of these $n$ numbers. Since the harmonic mean is less than or equal to the arithmetic mean for any set of positive numbers and the two means are equal only if $p_1 = p_2 = \cdots = p_n$, we conclude that the average cost per share for Mary is less than that for John if two of the prices $p_i$ are distinct. One can also give a proof based on the Cauchy-Schwarz inequality. To this end, define the vectors

$$a = (p_1^{-1/2}, p_2^{-1/2}, \ldots, p_n^{-1/2}) \quad b = (p_1^{1/2}, p_2^{1/2}, \ldots, p_n^{1/2})$$

Then $a \cdot b = 1 + \cdots + 1 = n$, and so by the Cauchy-Schwarz inequality

$$(a \cdot b)^2 = n^2 \leq \sum_{i=1}^{n} \frac{1}{p_i} \sum_{j=1}^{n} p_j$$

with the equality holding only if $p_1 = p_2 = \cdots = p_n$. Therefore

$$\frac{n}{\sum_{i=1}^{n} \frac{1}{p_i}} \leq \frac{\sum_{i=1}^{n} p_i}{n}$$

# MENSURATION FORMULAS

**REFERENCE:** http://mathworld.wolfram.com/SphericalSector.html, etc.

## PLANE GEOMETRIC FIGURES WITH STRAIGHT BOUNDARIES

Let $A$ denote area and $V$ volume in the following.

**Triangles** (see also "Plane Trigonometry") $A = \frac{1}{2}bh$ where $b$ = base, $h$ = altitude.

**Rectangle** $A = ab$ where $a$ and $b$ are the lengths of the sides.

**Parallelogram** (opposite sides parallel) $A = ah = ab \sin \alpha$ where $a$ and $b$ are the lengths of the sides, $h$ is the height, and $\alpha$ is the angle between the sides. See Fig. 3-3.

**Rhombus** (equilateral parallelogram) $A = \frac{1}{2}ab$ where $a$ and $b$ are the lengths of the diagonals.

**Trapezoid** (four sides, two parallel) $A = \frac{1}{2}(a + b)h$ where the lengths of the parallel sides are $a$ and $b$ and $h$ = height.

**Quadrilateral** (four-sided) $A = \frac{1}{2}ab \sin \theta$ where $a$ and $b$ are the lengths of the diagonals and the acute angle between them is $\theta$.

**Regular Polygon of *n* Sides** See Fig. 3-4.

$$A = \frac{1}{4} n l^2 \cot \frac{180^\circ}{n} \quad \text{where } l = \text{length of each side}$$

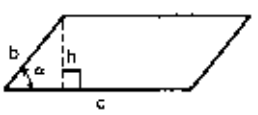

**FIG. 3-3** Parallelogram.

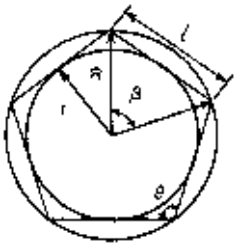

**FIG. 3-4** Regular polygon.

$R = \frac{l}{2}\csc\frac{180°}{n}$ where $R$ is the radius of the circumscribed circle

$r = \frac{l}{2}\cot\frac{180°}{n}$ where $r$ is the radius of the inscribed circle

***Radius* r *of Circle Inscribed in Triangle with Sides* a, b, c**

$$r = \sqrt{\frac{(s-a)(s-b)(s-c)}{s}} \quad \text{where } s = \tfrac{1}{2}(a+b+c)$$

***Radius* R *of Circumscribed Circle***

$$R = \frac{abc}{4\sqrt{s(s-a)(s-b)(s-c)}}$$

***Area of Regular Polygon of* n *Sides Inscribed in a Circle of Radius* r**

$$A = (nr^2/2)\sin(360°/n)$$

***Perimeter of Inscribed Regular Polygon***

$$P = 2nr\sin(180°/n)$$

***Area of Regular Polygon Circumscribed about a Circle of Radius* r**

$$A = nr^2\tan(180°/n)$$

***Perimeter of Circumscribed Regular Polygon***

$$P = 2nr\tan\frac{180°}{n}$$

## PLANE GEOMETRIC FIGURES WITH CURVED BOUNDARIES

**Circle** (see Fig. 3-5). Let
$C$ = circumference
$r$ = radius
$D$ = diameter
$A$ = area
$S$ = arc length subtended by θ
$l$ = chord length subtended by θ
$H$ = maximum rise of arc above chord, $r - H = d$
θ = central angle (rad) subtended by arc $S$
$C = 2\pi r = \pi D \qquad (\pi = 3.14159\ldots)$
$S = r\theta = \tfrac{1}{2}D\theta$

$$l = 2\sqrt{r^2 - d^2} = 2r\sin(\theta/2) = 2d\tan(\theta/2)$$

$$d = \frac{1}{2}\sqrt{4r^2 - l^2} = \frac{1}{2}l\cot\frac{\theta}{2}$$

$$\theta = \frac{S}{r} = 2\cos^{-1}\frac{d}{r} = 2\sin^{-1}\frac{l}{D}$$

$A$ (circle) $= \pi r^2 = \tfrac{1}{4}\pi D^2$
$A$ (sector) $= \tfrac{1}{2}rS = \tfrac{1}{2}r^2\theta$
$A$ (segment) $= A$ (sector) $- A$ (triangle) $= \tfrac{1}{2}r^2(\theta - \sin\theta)$

**Ring** (area between two circles of radii $r_1$ and $r_2$) The circles need not be concentric, but one of the circles must enclose the other.

$$A = \pi(r_1 + r_2)(r_1 - r_2) \qquad r_1 > r_2$$

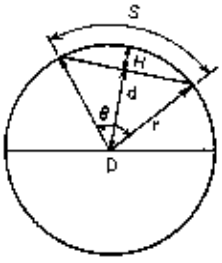

**FIG. 3-5** Circle.

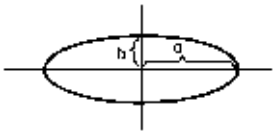

**FIG. 3-6** Ellipse.

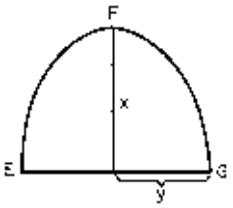

**FIG. 3-7** Parabola.

**Ellipse** (Fig. 3-6) Let the semiaxes of the ellipse be $a$ and $b$.

$$A = \pi ab$$

$$C = 4aE(e)$$

where $e^2 = 1 - b^2/a^2$ and $E(e)$ is the complete elliptic integral of the second kind

$$E(e) = \frac{\pi}{2}\left[1 - \left(\frac{1}{2}\right)^2 e^2 + \cdots\right]$$

[an approximation for the circumference $C = 2\pi\sqrt{(a^2 + b^2)/2)}$].

**Parabola** (Fig. 3-7)

$$\text{Length of arc } EFG = \sqrt{4x^2 + y^2} + \frac{y^2}{2x}\ln\frac{2x + \sqrt{4x^2 + y^2}}{y}$$

$$\text{Area of section } EFG = \frac{4}{3}xy$$

**Catenary** (the curve formed by a cord of uniform weight suspended freely between two points $A$ and $B$; Fig. 3-8)

$$y = a\cosh(x/a)$$

The length of arc between points $A$ and $B$ is equal to $2a\sinh(L/a)$. The sag of the cord is $D = a\cosh(L/a) - a$.

## SOLID GEOMETRIC FIGURES WITH PLANE BOUNDARIES

**Cube** Volume $= a^3$; total surface area $= 6a^2$; diagonal $= a\sqrt{3}$, where $a$ = length of one side of the cube.

**Rectangular Parallelepiped** Volume $= abc$; surface area $= 2(ab + ac + bc)$; diagonal $= \sqrt{a^2 + b^2 + c^2}$, where $a$, $b$, and $c$ are the lengths of the sides.

**Prism** Volume = (area of base) × (altitude); lateral surface area = (perimeter of right section) × (lateral edge).

**Pyramid** Volume = ⅓ (area of base) × (altitude); lateral area of regular pyramid = ½ (perimeter of base) × (slant height) = ½ (number of sides) (length of one side) (slant height).

**Frustum of Pyramid** It is formed from the pyramid by cutting off the top with a plane

$$V = \tfrac{1}{3}(A_1 + A_2 + \sqrt{A_1 \cdot A_2})h$$

where $h$ = altitude and $A_1$ and $A_2$ are the areas of the base; lateral area of a regular figure = ½ (sum of the perimeters of base) × (slant height).

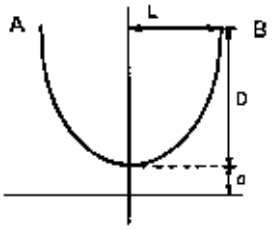

**FIG. 3-8** Catenary.

**Volume and Surface Area of Regular Polyhedra with Edge *l***

| Type of surface | Name | Volume | Surface area |
|---|---|---|---|
| 4 equilateral triangles | Tetrahedron | $0.1179l^3$ | $1.7321l^2$ |
| 6 squares | Hexahedron (cube) | $1.0000l^3$ | $6.0000l^2$ |
| 8 equilateral triangles | Octahedron | $0.4714l^3$ | $3.4641l^2$ |
| 12 pentagons | Dodecahedron | $7.6631l^3$ | $20.6458l^2$ |
| 20 equilateral triangles | Icosahedron | $2.1817l^3$ | $8.6603l^2$ |

## SOLIDS BOUNDED BY CURVED SURFACES

**Cylinders** (Fig. 3-9) $V$ = (area of base) × (altitude); lateral surface area = (perimeter of right section) × (lateral edge).

***Right Circular Cylinder*** $V = \pi$ (radius)$^2$ × (altitude); lateral surface area = $2\pi$ (radius) × (altitude).

***Truncated Right Circular Cylinder***

$$V = \pi r^2 h \qquad \text{lateral area} = 2\pi rh$$

$$h = \tfrac{1}{2}(h_1 + h_2)$$

***Hollow Cylinders*** Volume $= \pi h(R^2 - r^2)$, where $r$ and $R$ are the internal and external radii, respectively, and $h$ is the height of the cylinder.

**Sphere** See Fig. 3-10.

$V$ (sphere) $= \frac{4}{3}\pi R^3 = \frac{1}{6}\pi D^3$

$V$ (spherical sector) $= \frac{2}{3}\pi R^2 h_1$

$V$ (spherical segment of one base) $= \frac{1}{6}\pi h_1(3r_2^2 + h_1^2)$

$V$ (spherical segment of two bases) $= \frac{1}{6}\pi h_2(3r_1^2 + 3r_2^2 + h_2^2)$

$A$ (sphere) $= 4\pi R^2 = \pi D^2$

$A$ (zone) $= 2\pi Rh = \pi Dh$

$A$ (lune on surface included between two great circles, with inclination of $\theta$ radians) $= 2R^2\theta$.

**Cone** $V = \frac{1}{3}$ (area of base) × (altitude).

***Right Circular Cone*** $V = (\pi/3)r^2h$, where $h$ is the altitude and $r$ is the radius of the base; curved surface area $= \pi r\sqrt{r^2 + h^2}$, curved surface of the frustum of a right cone $= \pi(r_1 + r_2)\sqrt{h^2 + (r_1 - r_2)^2}$, where $r_1$ and $r_2$ are the radii of the base and top, respectively, and $h$ is the altitude; volume of the the frustum of a right cone $= \pi(h/3)(r_1^2 + r_1r_2 + r_2^2) = h/3\,(A_1 + A_2 + \sqrt{A_1A_2})$, where $A_1$ = area of base and $A_2$ = area of top.

**Ellipsoid** $V = (\frac{4}{3})\pi abc$, where $a$, $b$, and $c$ are the lengths of the semiaxes.

**Torus** (obtained by rotating a circle of radius $r$ about a line whose distance is $R > r$ from the center of the circle)

$$V = 2\pi^2Rr^2 \qquad \text{Surface area} = 4\pi^2Rr$$

**Prolate Spheroid** (formed by rotating an ellipse about its major axis $2a$)

$$\text{Surface area} = 2\pi b^2 + 2\pi(ab/e)\sin^{-1} e \qquad V = \tfrac{4}{3}\pi ab^2$$

where $a$ and $b$ are the major and minor axes and $e$ = eccentricity ($e < 1$).

**Oblate Spheroid** (formed by the rotation of an ellipse about its minor axis $2b$)

$$\text{Surface area} = 2\pi a^2 + \pi\frac{b^2}{e}\ln\frac{1+e}{1-e} \qquad V = \tfrac{4}{3}\pi a^2 b$$

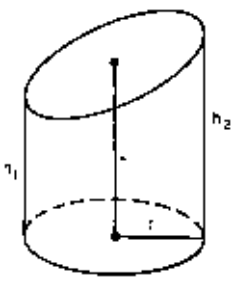

**FIG. 3-9** Cylinder.

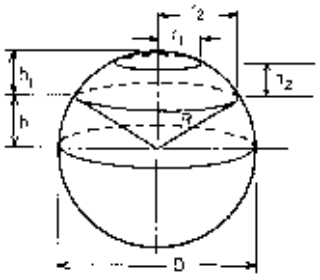

**FIG. 3-10** Sphere.

For process vessels, the formulas reduce to the following:

**Hemisphere** $V = \frac{\pi}{12}D^3 \qquad A = \frac{\pi}{2}D^2$

For a hemisphere (concave up) partially filled to a depth $h_1$, use the formulas for spherical segment with one base, which simplify to

$$V = \pi h_1^2(R - h_1/3) = \pi h_1^2(D/2 - h_1/3)$$
$$A = 2\pi Rh_1 = \pi Dh_1$$

For a hemisphere (concave down) partially filled from the bottom, use the formulas for a spherical segment of two bases, one of which is a plane through the center, where $h$ = distance from the center plane to the surface of the partially filled hemisphere.

$$V = \pi h(R^2 - h^2/3) = \pi h(D^2/4 - h^2/3)$$
$$A = 2\pi Rh = \pi Dh$$

**Cone** For a cone partially filled, use the same formulas as for right circular cones, but use $r$ and $h$ for the region filled.

**Ellipsoid** If the base of a vessel is one-half of an oblate spheroid (the cross section fitting to a cylinder is a circle with radius of $D/2$ and the minor axis is smaller), then use the formulas for one-half of an oblate spheroid.

$V = 0.1745D^3 \qquad S = 1.236D^2 \qquad \text{minor axis} = D/3$

$V = 0.1309D^3 \qquad S = 1.084D^2 \qquad \text{minor axis} = D/4$

## MISCELLANEOUS FORMULAS

See also "Differential and Integral Calculus."

**Volume of a Solid Revolution** (the solid generated by rotating a plane area about the $x$ axis)

$$V = \pi\int_a^b [f(x)]^2\,dx$$

where $y = f(x)$ is the equation of the plane curve and $a \le x \le b$.

**Area of a Surface of Revolution**

$$S = 2\pi\int_a^b y\,ds$$

where $ds = \sqrt{1 + (dy/dx)^2}\,dx$ and $y = f(x)$ is the equation of the plane curve rotated about the $x$ axis to generate the surface.

**Area Bounded by $f(x)$, the $x$ Axis, and the Lines $x = a$, $x = b$**

$$A = \int_a^b f(x)\,dx \qquad [f(x) \ge 0]$$

**Length of Arc of a Plane Curve**

If $y = f(x)$,

$$\text{Length of arc } s = \int_a^b \sqrt{1 + \left(\frac{dy}{dx}\right)^2}\,dx$$

If $x = f(t)$, $y = g(t)$,

$$\text{Length of arc } s = \int_{t_0}^{t_1} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2}\,dt$$

In general, $(ds)^2 = (dx)^2 + (dy)^2$.

## IRREGULAR AREAS AND VOLUMES

**Irregular Areas** Let $y_0, y_1, \ldots, y_n$ be the lengths of a series of equally spaced parallel chords and $h$ be their distance apart (Fig. 3-11). The area of the figure is given approximately by any of the following:

**FIG. 3-11** Irregular area.

$$A_T = (h/2)[(y_0 + y_n) + 2(y_1 + y_2 + \cdots + y_{n-1})] \qquad \text{(trapezoidal rule)}$$

$$A_s = (h/3)[(y_0 + y_n) + 4(y_1 + y_3 + y_5 + \cdots + y_{n-1}) + 2(y_2 + y_4 + \cdots + y_{n-2})] \qquad (n \text{ even, Simpson's rule})$$

The greater the value of $n$, the greater the accuracy of the approximation.

**Irregular Volumes** To find the volume, replace the $y$'s by cross-sectional areas $A_j$ and use the results in the preceding equations.

# ELEMENTARY ALGEBRA

**REFERENCES:** Stillwell, J., *Elements of Algebra*, Springer-Verlag, New York, 2010; Rich, B., and P. Schmidt, *Schaum's Outline of Elementary Algebra*, 3d ed., McGraw-Hill Education, New York, 2009.

## OPERATIONS ON ALGEBRAIC EXPRESSIONS

An algebraic expression will be denoted here as a combination of letters and numbers such as

$$3ax - 3xy + 7x^2 + 7x^{3/2} - 2.8xy$$

**Addition and Subtraction** Only like terms can be added or subtracted in two algebraic expressions.

***Example*** $(3x + 4xy - x^2) + (3x^2 + 2x - 8xy) = 5x - 4xy + 2x^2$.

**Multiplication** Multiplication of algebraic expressions is term by term, and corresponding terms are combined.

***Example*** $(2x + 3y - 2xy)(3 + 3y) = 6x + 9y + 9y^2 - 6xy^2$.

**Division** This operation is analogous to that in arithmetic.

***Example*** Divide $3e^{2x} + e^x + 1$ by $e^x + 1$.

$$\begin{array}{rl} & \text{Dividend} \\ \text{Divisor } \underline{e^x + 1} & \big| \, 3e^{2x} + e^x + 1 \qquad \underline{3e^x - 2} \text{ quotient} \\ & \underline{3e^{2x} + 3e^x} \\ & \quad -2e^x + 1 \\ & \quad \underline{-2e^x - 2} \\ & \qquad +3 \text{ (remainder)} \end{array}$$

Therefore, $3e^{2x} + e^x + 1 = (e^x + 1)(3e^x - 2) + 3$.

**Operations with Zero** All numerical computations (except division) can be done with zero. Both $a/0$ and $0/0$ have no meaning.

**Fractional Operations**

$$-\frac{x}{y} = -\left(\frac{-x}{-y}\right) = \frac{x}{-y} = \frac{-x}{y} \qquad \frac{x}{y} = \frac{-x}{-y} \qquad \frac{x}{y} = \frac{ax}{ay} \qquad \text{if } a \neq 0$$

$$\frac{x}{y} \pm \frac{z}{y} = \frac{x \pm z}{y} \qquad \left(\frac{x}{y}\right)\left(\frac{z}{t}\right) = \frac{xz}{yt} \qquad \frac{x/y}{z/t} = \left(\frac{x}{y}\right)\left(\frac{t}{z}\right) = \frac{xt}{yz}$$

**Factoring** It is that process of analysis consisting of reducing a given expression to the product of two or more simpler expressions, called *factors.* Some of the more common expressions are factored here:

(1) $x^2 - y^2 = (x - y)(x + y)$

(2) $x^2 + 2xy + y^2 = (x + y)^2$

(3) $x^3 - y^3 = (x - y)(x^2 + xy + y^2)$

(4) $x^3 + y^3 = (x + y)(x^2 - xy + y^2)$

(5) $x^4 - y^4 = (x - y)(x + y)(x^2 + y^2)$

(6) $x^5 + y^5 = (x + y)(x^4 - x^3y + x^2y^2 - xy^3 + y^4)$

(7) $x^n - y^n = (x - y)(x^{n-1} + x^{n-2}y + x^{n-3}y^2 + \cdots + y^{n-1})$

**Laws of Exponents**

$(a^n)^m = a^{nm}$; $a^{n+m} = a^n \cdot a^m$; $a^{n/m} = (a^n)^{1/m}$; $a^{n-m} = a^n / a^m$; $a^{1/m} = \sqrt[m]{a}$;

$a^{1/2} = \sqrt{a}$; $\sqrt{x^2} = |x|$ (absolute value of $x$). For $x > 0$, $y > 0$, $\sqrt{xy} = \sqrt{x}\sqrt{y}$;

for $x > 0$ $\sqrt[n]{x^m} = x^{m/n}$; $\sqrt[n]{1/x} = 1/\sqrt[n]{x}$

## BINOMIAL THEOREM

If $n$ is a positive integer, then

$$(a+b)^n = a^n + na^{n-1}b + \frac{n(n-1)}{2!}a^{n-2}b^2 + \frac{n(n-1)(n-2)}{3!}a^{n-3}b^3 + \cdots + b^n = \sum_{j=0}^{n}\binom{n}{j}a^{n-j}b^j$$

where $\binom{n}{j} = \dfrac{n!}{j!(n-j)!}$ = number of combination of $n$ things taken $j$ at a time

and $n! = 1 \cdot 2 \cdot 3 \cdot 4 \cdots n$, $0! = 1$.

***Example*** $(x+y)^4 = x^4 + 4x^3y + 6x^2y^2 + 4xy^3 + y^4$.

If $n$ is not a positive integer, the sum formula no longer applies and an infinite series results for $(a + b)^n$.

***Example*** $(1+x)^{1/2} = 1 + \frac{1}{2}x - \frac{1}{2} \cdot \frac{1}{4}x^2 + \frac{1}{2} \cdot \frac{1}{4} \cdot \frac{3}{6}x^3 \cdots$ (convergent for $x^2 < 1$). Additional discussion can be found under "Infinite Series."

## PROGRESSIONS

An *arithmetic progression* is a succession of terms such that each term, except the first, is derivable from the preceding by the addition of a quantity $d$, called the *common difference*. All arithmetic progressions have the form $a$, $a + d$, $a + 2d$, $a + 3d$, …. With $a$ = first term, $l$ = last term, $d$ = common difference, $n$ = number of terms, and $s$ = sum of the terms, the following relations hold:

$$l = a + (n-1)d = \frac{s}{n} + \frac{n-1}{2}d$$

$$s = \frac{n}{2}[2a + (n-1)d] = \frac{n}{2}(a + l) = \frac{n}{2}[2l - (n-1)d]$$

$$a = l - (n-1)d = \frac{s}{n} - \frac{(n-1)d}{2} = \frac{2s}{n} - l$$

$$d = \frac{l-a}{n-1} = \frac{2(s-an)}{n(n-1)} = \frac{2(nl-s)}{n(n-1)}$$

$$n = \frac{l-a}{d} + 1 = \frac{2s}{l+a}$$

The *arithmetic mean* or *average* of two numbers $a$ and $b$ is $(a + b)/2$ and of $n$ numbers $a_1, \ldots, a_n$ is $(a_1 + a_2 + \cdots + a_n)/n$.

A *geometric progression* is a succession of terms such that each term, except the first, is derivable from the preceding by the multiplication of a quantity $r$ called the *common ratio*. All such progressions have the form $a$, $ar$, $ar^2$, …, $ar^{n-1}$. With $a$ = first term, $l$ = last term, $r$ = ratio, $n$ = number of terms, and $s$ = sum of the terms, the following relations hold:

$$l = ar^{n-1} = \frac{a + (r-1)s}{r} = \frac{(r-1)\,sr^{n-1}}{r^n - 1}$$

$$s = \frac{a(r^n - 1)}{r - 1} = \frac{a(1 - r^n)}{1 - r} = \frac{rl - a}{r - 1} = \frac{lr^n - l}{r^n - r^{n-1}}$$

$$a = \frac{l}{r^{n-l}} = \frac{(r-1)s}{r^n - 1}, \quad r = \frac{s-a}{s-l}, \quad \log r = \frac{\log l - \log a}{n-1}$$

$$n = \frac{\log l - \log a}{\log r} + 1 = \frac{\log[a + (r-1)s] - \log a}{\log r}$$

The geometric mean of two nonnegative numbers $a$ and $b$ is $\sqrt{ab}$; of $n$ numbers is $(a_1 a_2 \ldots a_n)^{1/n}$. The geometric mean of a set of positive numbers is less than or equal to the arithmetic mean.

***Example*** Find the sum of $1 + \frac{1}{2} + \frac{1}{4} + \cdots + \frac{1}{64}$. Here $a = 1$, $r = \frac{1}{2}$, $n = 7$. Thus

$$s = \frac{\frac{1}{2}(\frac{1}{64}) - 1}{\frac{1}{2} - 1} = 127/64$$

$$s = a + ar + ar^2 + \cdots + ar^{n-1} = \frac{a}{1-r} - \frac{ar^n}{1-r}$$

If $|r| < 1$, then $\lim_{n \to \infty} s = \dfrac{a}{1-r}$

which is called the *sum of the infinite geometric progression.*

***Example*** The present worth (PW) of a series of cash flows $C_k$ at the end of year $k$ is

$$\mathrm{PW}=\sum_{k=1}^{n}\frac{C_k}{(1+i)^k}$$

where $i$ is an assumed interest rate. (Thus the present worth always requires specification of an interest rate.) If all the payments are the same, $C_k = R$, then the present worth is

$$\mathrm{PW}=R\sum_{k=1}^{n}\frac{1}{(1+i)^k}$$

This can be rewritten as

$$\mathrm{PW}=\frac{R}{1+i}\sum_{k=1}^{n}\frac{1}{(1+i)^{k-1}}=\frac{R}{1+i}\sum_{j=0}^{n-1}\frac{1}{(1+i)^j}$$

This is a geometric series with $r = 1/(1 + i)$ and $a = R/(1 + i)$. The formulas above give

$$\mathrm{PW}\,(=s)=\frac{R}{i}\frac{(1+i)^n-1}{(1+i)^n}$$

The same formula applies to the value of an annuity (PW) now, to provide for equal payments $R$ at the end of each of $n$ years, with interest rate $i$.

A progression of the form $a$, $(a + d)r$, $(a + 2d)r^2$, $(a + 3d)r^3$, etc., is a combined arithmetic and geometric progression. The sum of $n$ such terms is

$$s=\frac{a-[a+(n-1)d]r^n}{1-r}+\frac{rd(1-r^{n-1})}{(1-r)^2}$$

If $|r|<1$, $\lim_{n\to\infty} s=\dfrac{a}{1-r}+rd/(1-r)^2$.

The nonzero numbers $a$, $b$, $c$, etc., form a *harmonic progression* if their reciprocals $1/a$, $1/b$, $1/c$, etc., form an arithmetic progression.

***Example*** The progression 1, ⅓, ⅕, ⅐, …, 1/31 is harmonic since 1, 3, 5, 7, …, 31 form an arithmetic progression.

The *harmonic mean* of two numbers $a$ and $b$ is $2ab/(a + b)$.

## PERMUTATIONS, COMBINATIONS, AND PROBABILITY

Each separate arrangement of all or a part of a set of things is called a *permutation*. The number of permutations of $n$ things taken $r$ at a time is written

$$P(n,r)=\frac{n!}{(n-r)!}=n(n-1)(n-2)\cdots(n-r+1)$$

Each separate selection of objects that is possible irrespective of the order in which they are arranged is called a *combination*. The number of combinations of $n$ things taken $r$ at a time is written $C(n, r) = n!/[r!(n - r)!]$.

An important relation is $r!C(n, r) = P(n, r)$.

If an event can occur in $p$ ways and can fail to occur in $q$ ways, with all ways being equally likely, the *probability* of its occurrence is $p/(p + q)$, and that of its failure is $q/(p + q)$.

***Example*** Two dice may be thrown in 36 separate ways. What is the probability of throwing such that their sum is 7? The number 7 may arise in 6 ways: 1 and 6, 2 and 5, 3 and 4, 4 and 3, 5 and 2, 6 and 1. The probability of shooting a 7 is ⅙.

## THEORY OF EQUATIONS

**Linear Equations** A linear equation is one of the first degree (i.e., only the first powers of the variables are involved), and the process of obtaining definite values for the unknown is called *solving the equation*. Every linear equation in one variable is written $Ax + B = 0$ or $x = -B/A$. Linear equations in $n$ variables have the form

$$\begin{aligned}
a_{11}x_1+a_{12}x_2+\cdots+a_{1n}x_n&=b_1\\
a_{21}x_1+a_{22}x_2+\cdots+a_{2n}x_n&=b_2\\
&\vdots\\
a_{m1}x_1+a_{m2}x_2+\cdots+a_{mn}x_n&=b_m
\end{aligned}$$

The solution of the system may then be found by elimination or matrix methods if a solution exists (see Matrix Algebra and Matrix Computations).

**Quadratic Equations** Every quadratic equation in one variable is expressible in the form $ax^2 + bx + c = 0$, $a \neq 0$. This equation has two solutions, say, $x_1$ and $x_2$, given by

$$\left.\begin{matrix}x_1\\x_2\end{matrix}\right\}=\frac{-b\pm\sqrt{b^2-4ac}}{2a}$$

If $a$, $b$, and $c$ are real, the discriminant $b^2 - 4ac$ gives the character of the roots. If $b^2 - 4ac > 0$, the roots are real and unequal. If $b^2 - 4ac < 0$, the roots are complex conjugates. If $b^2 - 4ac = 0$, the roots are *real* and *equal*. Two quadratic equations in two variables in general can be solved only by numerical methods (see Numerical Analysis and Approximate Methods).

**Cubic Equations** A cubic equation in one variable has the form $x^3 + bx^2 + cx + d = 0$. Every cubic equation having complex coefficients has three complex roots. If the coefficients are real numbers, then at least one of the roots must be real. The cubic equation $x^3 + bx^2 + cx + d = 0$ may be reduced by the substitution $x = y - b/3$ to the form $y^3 + py + q = 0$, where $p = ⅓(3c - b^2)$ and $q = 1/27(27d - 9bc + 2b^3)$.

This reduced equation has the solutions

$$y_1=A+B,\quad y_2=-½(A+B)+(i\sqrt{3}/2)(A-B),$$

$$y_3=-½(A+B)-(i\sqrt{3}/2)(A-B),\ \text{where } i^2=-1,\ A=\sqrt[3]{-q/2+\sqrt{R}},$$

$$B=\sqrt[3]{-q/2-\sqrt{R}},\ \text{and } R=(p/3)^3+(q/2)^2.$$

If $b$, $c$, and $d$ are all real and if $R > 0$, there are one real root and two conjugate complex roots; if $R = 0$, there are three real roots, of which at least two are equal; if $R < 0$, there are three real unequal roots. If $R < 0$, which requires $p < 0$, these formulas are impractical. In this case, the roots are given by $y_k=\mp 2\sqrt{-p/3}\cos[(\varphi/3)+120k]$, $k = 0, 1, 2$, where

$$\phi=\cos^{-1}\sqrt{\frac{q^2/4}{-p^3/27}}$$

and the negative sign applies if $q > 0$, and the positive sign applies if $q < 0$.

***Example*** Many equations of state involve solving cubic equations for the compressibility factor $Z$. For example, the Soave-Redlich-Kwong equation of state requires solving

$$Z^3-Z^2+cZ+d=0\qquad d<0$$

where $c$ and $d$ depend on critical constants of the chemical species and temperature and pressure. In this case, only positive solutions, $Z > 0$, are desired.

**Quartic Equations** See Olver et al. (2010) in General References.

**General Polynomials of the *n*th Degree** If $n > 4$, there is no formula that gives the roots of the general equation. The roots can be found numerically (see "Numerical Analysis and Approximate Methods").

***Fundamental Theorem of Algebra*** Every polynomial of degree $n$ has exactly $n$ real or complex roots, counting multiplicities.

**Determinants** Consider the system of two linear equations

$$\begin{aligned}
a_{11}x_1+a_{12}x_2&=b_1\\
a_{21}x_1+a_{22}x_2&=b_2
\end{aligned}$$

If the first equation is multiplied by $a_{22}$ and the second by $-a_{12}$ and the results are added, we obtain

$$(a_{11}a_{22}-a_{21}a_{12})x_1=b_1a_{22}-b_2a_{12}$$

The expression $a_{11}a_{22} - a_{21}a_{12}$ may be represented by the symbol

$$\begin{vmatrix}a_{11}&a_{12}\\a_{21}&a_{22}\end{vmatrix}=a_{11}a_{22}-a_{21}a_{12}$$

This symbol is called a *determinant of second order*. The value of the square array of $n^2$ quantities $a_{ij}$, where $i = 1, \ldots, n$, is the row index, $j = 1, \ldots, n$. The column index, written in the form

$$|A|=\begin{vmatrix}a_{11}&a_{12}&a_{13}\cdots a_{1n}\\a_{21}&a_{22}&\cdots\cdots a_{2n}\\\vdots&&\\a_{n1}&a_{n2}&a_{n3}\cdots a_{nn}\end{vmatrix}$$

is called a *determinant.* The $n^2$ quantities $a_{ij}$ are called the *elements* of the determinant. In the determinant $|A|$, let the $i$th row and $j$th column be deleted and a new determinant be formed having $n-1$ rows and columns. This new determinant is called the *minor* of $a_{ij}$, denoted $M_{ij}$.

***Example*** $\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix}$ The minor of $a_{23}$ is $M_{23} = \begin{vmatrix} a_{11} & a_{12} \\ a_{31} & a_{32} \end{vmatrix}$

The cofactor $A_{ij}$ of the element $a_{ij}$ is the signed minor of $a_{ij}$ determined by the rule $A_{ij} = (-1)^{i+j}M_{ij}$. The *value* of $|A|$ is obtained by forming any of the equivalent expressions $\sum_{j=1}^{n} a_{ij}A_{ij}$, $\sum_{i=1}^{n} a_{ij}A_{ij}$, where the elements $a_{ij}$ must be taken from a single row or a single column of $A$.

***Example***

$$\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix} = a_{31}A_{31} + a_{32}A_{32} + a_{33}A_{33}$$

$$= a_{31}\begin{vmatrix} a_{12} & a_{13} \\ a_{22} & a_{23} \end{vmatrix} - a_{32}\begin{vmatrix} a_{11} & a_{13} \\ a_{21} & a_{23} \end{vmatrix} + a_{33}\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix}$$

In general, $A_{ij}$ will be determinants of order $n-1$, but they may in turn be expanded by the rule. Also,

$$\sum_{j=1}^{n} a_{ji}A_{jk} = \sum_{j=1}^{n} a_{ij}A_{jk} = \begin{cases} |A| & i = k \\ 0 & i \neq k \end{cases}$$

***Fundamental Properties of Determinants***

1. The value of a determinant $|A|$ is not changed if the rows and columns are interchanged.
2. If the elements of one row (or one column) of a determinant are all zero, the value of $|A|$ is zero.
3. If the elements of one row (or column) of a determinant are multiplied by the same constant factor, the value of the determinant is multiplied by this factor.
4. If one determinant is obtained from another by interchanging any two rows (or columns), the value of either is the negative of the value of the other.
5. If two rows (or columns) of a determinant are identical, the value of the determinant is zero.
6. If two determinants are identical except for one row (or column), the sum of their values is given by a single determinant obtained by adding corresponding elements of dissimilar rows (or columns) and leaving unchanged the remaining elements.
7. The value of a determinant is not changed if one row (or column) is multiplied by a constant and added to another row (or column).

# ANALYTIC GEOMETRY

**REFERENCES:** Gersting, J. L., *Technical Calculus with Analytic Geometry*, Dover, Mineola, N.Y., 2010.

Analytic geometry uses algebraic equations and methods to study geometric problems. It also permits one to visualize algebraic equations in terms of geometric curves, which frequently clarifies abstract concepts.

## PLANE ANALYTIC GEOMETRY

**Coordinate Systems** The basic concept of analytic geometry is the establishment of a one-to-one correspondence between the points of the plane and number pairs $(x, y)$. This correspondence may be done in a number of ways. The rectangular or cartesian coordinate system consists of two straight lines intersecting at right angles (Fig. 3-12). A point is designated by $(x, y)$. Another common coordinate system is the polar coordinate system (Fig. 3-13). In this system the position of a point is designated by the pair $(r, \theta)$, with $r = \sqrt{x^2 + y^2}$ being the distance to the origin $O(0, 0)$ and $\theta$ being the angle the line $r$ makes with the positive $x$ axis (polar axis). To change from polar to rectangular coordinates, use $x = r\cos\theta$ and $y = r\sin\theta$. To change from rectangular to polar coordinates, use $r = \sqrt{x^2 + y^2}$ and $\theta = \tan^{-1}(y/x)$ if $x \neq 0$; $\theta = \pi/2$ if $x = 0$. The distance between two points $(x_1, y_1)$ and $(x_2, y_2)$ is defined by $d = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}$ in rectangular coordinates or by $d = \sqrt{r_1^2 + r_2^2 - 2r_1r_2\cos(\theta_1 - \theta_2)}$ in polar coordinates. Other coordinate systems are sometimes used. For example, on the surface of a sphere, latitude and longitude prove useful.

**Straight Line** See Fig. 3-14. The slope $m$ of a straight line is the tangent of the inclination angle $\theta$ made with the positive $x$ axis. If $(x_1, y_1)$ and $(x_2, y_2)$ are any two points on the line, then slope $= m = (y_2 - y_1)/(x_2 - x_1)$. The slope of a line parallel to the $x$ axis is zero; the slope of a line parallel to the $y$ axis is undefined. Two lines are parallel if and only if they have the same slope. Two lines are perpendicular if and only if the product of their slopes is $-1$ (the exception being that case when the lines are parallel to the coordinate axes). Every equation of the type $Ax + By + C = 0$ represents a straight line, and every straight line has an equation of this form. A straight line is determined by a variety of conditions:

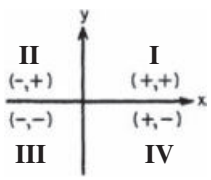

**FIG. 3-12** Rectangular coordinates.

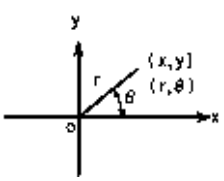

**FIG. 3-13** Polar coordinates.

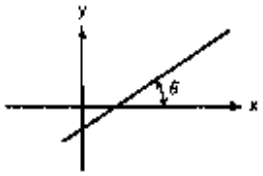

**FIG. 3-14** Straight line.

| Given conditions | Equation of line |
|---|---|
| 1. Parallel to $x$ axis | $y =$ constant |
| 2. Parallel to $y$ axis | $x =$ constant |
| 3. Point $(x_1, y_1)$ and slope $m$ | $y - y_1 = m(x - x_1)$ |
| 4. Intercept on $y$ axis $(0, b)$, $m$ | $y = mx + b$ |
| 5. Intercept on $x$ axis $(a, 0)$, $m$ | $y = m(x - a)$ |
| 6. Two points $(x_1, y_1)$, $(x_2, y_2)$ | $y - y_1 = \frac{y_2 - y_1}{x_2 - x_1}(x - x_1)$ |
| 7. Two intercepts $(a, 0)$, $(0, b)$ | $x/a + y/b = 1$ |

The angle $\beta$ that a line with slope $m_1$ makes with a line having slope $m_2$ is given by $\tan\beta = (m_2 - m_1)/(m_1m_2 + 1)$. The distance from a point $(x_1, y_1)$ to a line with equation $Ax + By + C = 0$ is

$$d = \frac{|Ax_1 + By_1 + C|}{\sqrt{A^2 + B^2}}$$

Occasionally some nonlinear algebraic equations can be reduced to linear equations under suitable substitutions or changes of variables.

***Example*** Consider $y = bx^n$ and $B = \log b$. Taking logarithms gives $\log y = n\log x + \log b$. Let $Y = \log y$, $X = \log x$, and $B = \log b$. The equation then has the form $Y = nX + B$, which is a linear equation. Consider $k = k_0\exp(-E/RT)$; taking logarithms gives $\ln k = \ln k_0 - E/(RT)$. Let

$$Y = \ln k,\ B = \ln k_0,\ m = -E/R, \text{ and } X = 1/T, \text{ and the result is } Y = mX + B.$$

**Asymptotes** The limiting position of the tangent to a curve, as the point of contact tends to an infinite distance from the origin, is called an *asymptote.*

**Conic Sections** The curves included in this group are obtained from plane sections of the cone. They include the circle, ellipse, parabola, hyperbola, and degeneratively the point and straight line. A *conic* is the locus of a point whose distance from a fixed point called the *focus* is in a constant

ratio to its distance from a fixed line, called the *directrix*. This ratio is the eccentricity *e*. If $e = 0$, the conic is a circle; if $0 < e < 1$, the conic is an ellipse; if $e = 1$, the conic is a parabola; if $e > 1$, the conic is a hyperbola. Every conic section is representable by an equation of second degree. Conversely, every equation of second degree in two variables represents a conic. The general equation of the second degree is $Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0$. Let $\Delta$ be defined as the determinant

$$\Delta = \begin{vmatrix} 2A & B & D \\ B & 2C & E \\ D & E & 2F \end{vmatrix}$$

The table characterizes the curve represented by the equation.

| | $B^2 - 4AC < 0$ | $B^2 - 4AC = 0$ | $B^2 - 4AC > 0$ |
|---|---|---|---|
| $\Delta \neq 0$ | $A\Delta < 0, A \neq C$, an ellipse<br>$A\Delta < 0, A = C$, a circle<br>$A\Delta > 0$, no locus | Parabola | Hyperbola |
| $\Delta = 0$ | Point | Two parallel lines if $Q = D^2 + E^2 - 4(A + C)F > 0$<br>One straight line if $Q = 0$<br>no locus if $Q < 0$ | Two intersecting straight lines |

| | | |
|---|---|---|
| (1) $(x-h)^2+(y-k)^2-a^2$ | $x = h + a\cos\theta$ | Circle (Fig. 3-15) parameter is angle $\theta$ |
| | $y = k + a\sin\theta$ | Ellipse (Fig. 3-16) parameter is angle $\theta$ |
| (2) $\frac{(x-h)^2}{a^2}+\frac{(y-k)^2}{b^2}=1$ | $x = h + a\cos\phi$<br>$y = k + a\sin\phi$ | |
| (3) $x^2+y^2=a^2$ | $\begin{cases} x = \frac{-at}{\sqrt{t^2+1}} \\ y = \frac{a}{\sqrt{t^2+1}} \end{cases}$ | Circle parameter is $t = \frac{dy}{dx}$ = slope of tangent at $(x, y)$ |
| (4) $x^2 = y + k$ | | Parabola (Fig. 3-17) |
| (5) $\frac{x^2}{a^2}-\frac{y^2}{b^2}=1$ | | Hyperbola with the origin at the center (Fig. 3-18) |
| (6) $y = a\cosh\frac{x}{a}$ | $\begin{cases} x = a\sinh^{-1}\frac{s}{a} \\ y^2 = a^2 + s^2 \end{cases}$ | Catenary (such as hanging cable under gravity)<br>Parameter $s$ = arc length from $(0, a)$ to $(x, y)$ |
| (7) Cycloid | $\begin{cases} x = a(\phi - \sin\phi) \\ y = a(1 - \cos\phi) \end{cases}$ | (Fig. 3-19) |

***Example*** $3x^2 + 4xy - 2y^2 + 3x - 2y + 7 = 0$.

$$\Delta = \begin{vmatrix} 6 & 4 & 3 \\ 4 & -4 & -2 \\ 3 & -2 & 14 \end{vmatrix} = -596 \neq 0,\ B^2 - 4AC = 40 > 0$$

The curve is therefore a hyperbola.

| Polar equation | Type of curve |
|---|---|
| (1) $r = a$ | Circle, Fig. 3-20 |
| (2) $r = 2a\cos\theta$ | Circle, Fig. 3-21 |
| (3) $r = 2a\sin\theta$ | Circle, Fig. 3-22 |
| (4) $r^2 - 2br\cos(\theta - \beta) + b^2 - a^2 = 0$ | Circle at $(b, \beta)$, radius $a$ |
| (5) $r = \frac{ke}{1 - e\cos\theta}$ | $e = 1$ parabola, Fig. 3-17<br>$0 < e < 1$ ellipse, Fig. 3-16<br>$e > 1$ hyperbola, Fig. 3-18 |

**Parametric Equations** It is frequently useful to write the equations of a curve in terms of a parameter. For example, a circle of radius *a*, center at (0, 0), can be written in the equivalent form $x = a\cos\phi$, $y = a\sin\phi$, where $\phi$ is the parameter. Similarly, $x = a\cos\phi$ and $y = b\sin\phi$ are the parametric equations of the ellipse $x^2/a^2 + y^2/b^2 = 1$ with parameter $\phi$.

## SOLID ANALYTIC GEOMETRY

**Coordinate Systems** There are three commonly used coordinate systems. Others may be used in specific problems (see Morse, P. M., and H. Feshbach, *Methods of Theoretical Physics*, vols. 1 and I2, McGraw-Hill, New York, 1953). The *rectangular* (cartesian) system (Fig. 3-23) consists of mutually orthogonal axes *x*, *y*, and *z*. A triple of numbers $(x, y, z)$ is used to represent each point. The *cylindrical* coordinate system $(r, \theta, z$; Fig. 3-24) is frequently used to locate a point in space. These are essentially the polar coordinates $(r, \theta)$ coupled with the *z* coordinate. As before, $x = r\cos\theta$, $y = r\sin\theta$, $z = z$ and $r^2 = x^2 + y^2$, $y/x = \tan\theta$. If *r* is held constant and $\theta$ and *z* are allowed to vary, the locus of $(r, \theta, z)$ is a right circular cylinder of radius *r* along the *z* axis. The locus of $r = C$ is a circle, and $\theta$ = constant is a plane containing the *z* axis and making an angle $\theta$ with the *xz* plane. Cylindrical coordinates are convenient to use when the problem has an axis of symmetry.

The **spherical** coordinate system is convenient if there is a point of symmetry in the system. This point is taken as the origin and the coordinates $(\rho, \phi, \theta)$ are illustrated in Fig. 3-25. The relations are $x = \rho\sin\phi\cos\theta$, $y = \rho\sin\phi\sin\theta$, $z = \rho\cos\phi$, and $r = \rho\sin\phi$. Also $\theta$ = constant is a plane containing the *z* axis and making an angle $\theta$ with the *xz* plane; $\phi$ = constant is a cone with vertex at 0; $\rho$ = constant is the surface of a sphere of radius $\rho$, center at the origin 0. Every point in the space may be given spherical coordinates restricted to the ranges $0 \le \phi \le \pi$, $\rho \ge 0$, $0 \le \theta < 2\pi$.

**Lines and Planes** The distance between two points $(x_1, y_1, z_1)$, $(x_2, y_2, z_2)$ is $d = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2 + (z_1 - z_2)^2}$. There is nothing in the geometry of three dimensions quite analogous to the slope of a line in

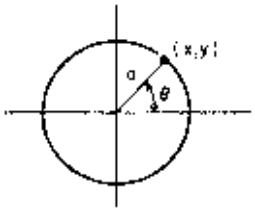

**FIG. 3-15** Circle.

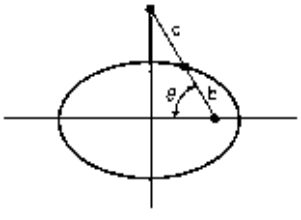

**FIG. 3-16** Ellipse, $0 < e < 1$.

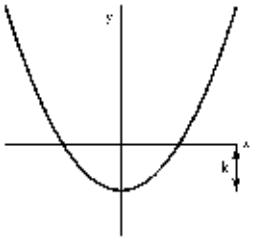

**FIG. 3-17** Parabola, $e = 1$.

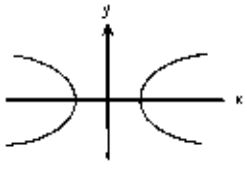

**FIG. 3-18** Hyperbola, $e > 1$.

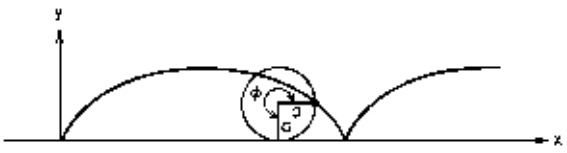

**FIG. 3-19** Cycloid.

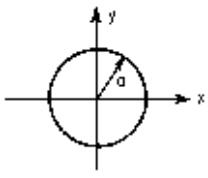

**FIG. 3-20** Circle center $(0, 0)$, $r = a$.

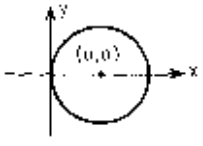

**FIG. 3-21** Circle center $(a, 0)$, $r = 2a\cos\theta$.

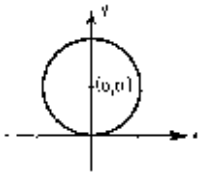

**FIG. 3-22** Circle center $(0, a)$, $r = 2a \sin \theta$.

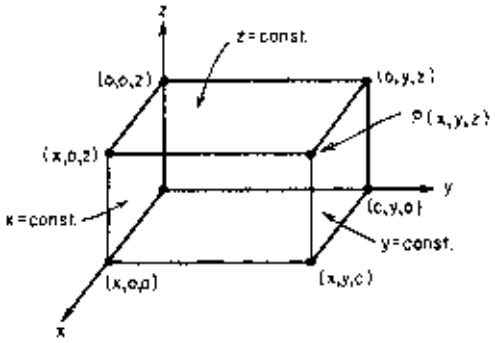

**FIG. 3-23** Cartesian coordinates.

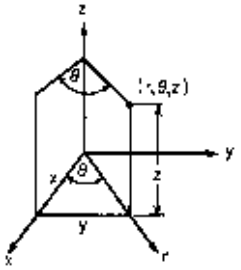

**FIG. 3-24** Cylindrical coordinates.

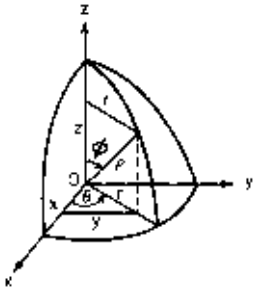

**FIG. 3-25** Spherical coordinates.

the plane. Instead of specifying the direction of a line by a trigonometric function evaluated for one angle, a trigonometric function evaluated for three angles is used. The angles $\alpha$, $\beta$, and $\gamma$ that a line segment makes with the positive $x$, $y$, and $z$ axes, respectively, are called the *direction angles* of the line, and $\cos \alpha$, $\cos \beta$, and $\cos \gamma$ are called the *direction cosines*. Let $(x_1, y_1, z_1)$ and $(x_2, y_2, z_2)$ be on the line. Then $\cos \alpha = (x_2 - x_1)/d$, $\cos \beta = (y_2 - y_1)/d$, and $\cos \gamma = (z_2 - z_1)/d$, where $d$ = the distance between the two points. Clearly $\cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1$. If two lines are specified by the direction cosines $(\cos \alpha_1, \cos \beta_1, \cos \gamma_1)$ and $(\cos \alpha_2, \cos \beta_2, \cos \gamma_2)$, then the angle $\theta$ between the lines is $\cos \theta = \cos \alpha_1 \cos \alpha_2 + \cos \beta_1 \cos \beta_2 + \cos \gamma_1 \cos \gamma_2$. Thus the lines are perpendicular if and only if $\theta = 90°$ or $\cos \alpha_1 \cos \alpha_2 + \cos \beta_1 \cos \beta_2 + \cos \gamma_1 \cos \gamma_2 = 0$. The equation of a line with direction cosines $(\cos \alpha, \cos \beta, \cos \gamma)$ passing through $(x_1, y_1, z_1)$ is $(x - x_1)/\cos \alpha = (y - y_1)/\cos \beta = (z - z_1)/\cos \gamma$.

The equation of every plane is of the form $Ax + By + Cz + D = 0$. The numbers

$$\frac{A}{\sqrt{A^2+B^2+C^2}}, \frac{B}{\sqrt{A^2+B^2+C^2}}, \frac{C}{\sqrt{A^2+B^2+C^2}}$$

are direction cosines of the normal lines to the plane. The plane through the point $(x_1, y_1, z_1)$ whose normals have these as direction cosines is $A(x - x_1) + B(y - y_1) + C(z - z_1) = 0$.

***Example*** Find the equation of the plane through (1, 5, –2) perpendicular to the line $(x + 9)/7 = (y - 3)/(-1) = z/8$. The numbers (7, –1, 8) are called *direction numbers*. They are a constant multiple of the direction cosines $\cos \alpha = 7/114$, $\cos \beta = -1/114$, and $\cos \gamma = 8/114$. The plane has the equation $7(x - 1) - 1(y - 5) + 8(z + 2) = 0$ or $7x - y + 8z + 14 = 0$.

The distance from the point $(x_1, y_1, z_1)$ to the plane $Ax + By + Cz + D = 0$ is

$$d = \frac{|Ax_1 + By_1 + Cz_1 + D|}{\sqrt{A^2 + B^2 + C^2}}$$

**Space Curves** Space curves are usually specified as the set of points whose coordinates are given parametrically by a system of equations $x = f(t)$, $y = g(t)$, $z = h(t)$ in the parameter $t$.

***Example*** The equation of a straight line in space is $(x - x_1)/a = (y - y_1)/b = (z - z_1)/c$. Since all these quantities must be equal (say, to $t$), we may write $x = x_1 + at$, $y = y_1 + bt$, and $z = z_1 + ct$, which represent the parametric equations of the line.

***Example*** The equations $z = a \cos \beta t$, $y = a \sin \beta t$, and $z = bt$, with $a$, $\beta$, and $b$ positive constants, represent a circular helix.

**Surfaces** The locus of points $(x, y, z)$ satisfying $f(x, y, z) = 0$, broadly speaking, may be interpreted as a surface. The simplest surface is the *plane*. The next simplest is a *cylinder*.

***Example*** The parabolic cylinder $y = x^2$ (Fig. 3-26) is generated by a straight line parallel to the $z$ axis passing through $y = x^2$ in the plane $z = 0$. A surface whose equation is a quadratic in the variables $x$, $y$, and $z$ is called a *quadric surface*. Some of the more common such surfaces are tabulated and pictured in Figs. 3-26 to 3-34.

# PLANE TRIGONOMETRY

**REFERENCES:** Gelfand, I. M., and M. Saul, *Trigonometry*, Birkhäuser, Boston, 2001; Heineman, E. Richard, and J. Dalton Tarwater, *Plane Trigonometry*, 7th ed., McGraw-Hill, New York, 1993.

## ANGLES

An angle is generated by the rotation of a line about a fixed center from some initial position to some terminal position. If the rotation is clockwise, the angle is negative; if it is counterclockwise, the angle is positive. Angle size is unlimited. If $\alpha$ and $\beta$ are two angles such that $\alpha + \beta = 90°$, they are complementary; they are supplementary if $\alpha + \beta = 180°$. Angles are most commonly measured in the sexagesimal system or by radian measure. In the first system there are 360° in 1 complete revolution (1 r); 1° = ⅑₀ of a right angle. The degree is subdivided into 60 minutes; the minute is subdivided into 60 seconds. In the radian system, 1 radian (1 rad) is the angle at the center of a circle subtended by an arc whose length is equal to the radius of the circle. Thus $2\pi$ rad = 360°; 1 rad = 57.29578°; 1° = 0.01745 rad; 1 min = 0.00029089 rad. The advantage of radian measure is that it is *dimensionless.* The quadrants are conventionally labeled, as Fig. 3-35 shows.

## FUNCTIONS OF CIRCULAR TRIGONOMETRY

The trigonometric functions of angles are the ratios between the various sides of the reference triangles shown in Fig. 3-36 for the various quadrants. Clearly $r=\sqrt{x^2+y^2}\geq 0$. The fundamental functions (see Figs. 3-37, 3-38, 3-39) are as follows:

**Plane Trigonometry**

| | |
|---|---|
| Sine of $\theta = \sin\theta = y/r$ | Secant of $\theta = \sec\theta = r/x$ |
| Cosine of $\theta = \cos\theta = x/r$ | Cosecant of $\theta = \csc\theta = r/y$ |
| Tangent of $\theta = \tan\theta = y/x$ | Cotangent of $\theta = \cot\theta = x/y$ |

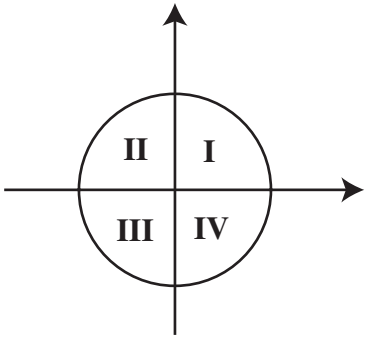

**FIG. 3-35** Quadrants.

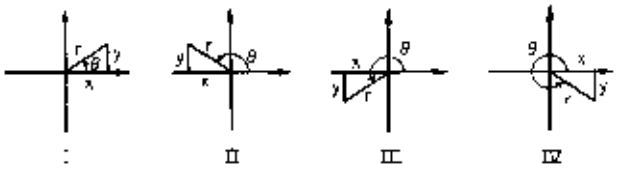

**FIG. 3-36** Triangles.

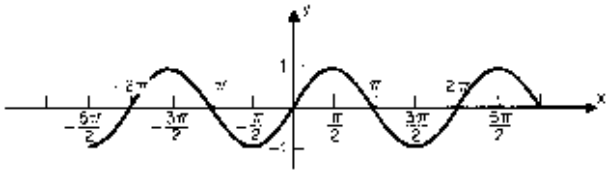

**FIG. 3-37** Graph of $y = \sin x$.

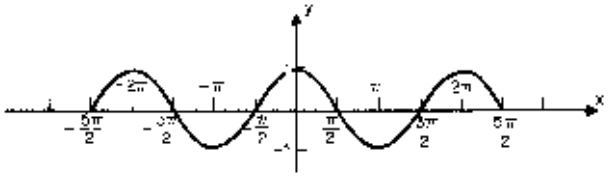

**FIG. 3-38** Graph of $y = \cos x$.

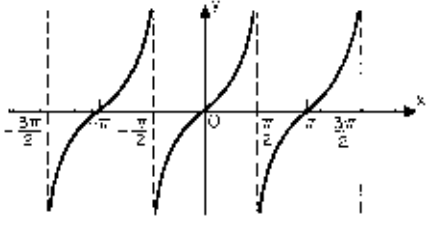

**FIG. 3-39** Graph of $y = \tan x$.

**Values of the Trigonometric Functions for Common Angles**

| θ° | θ, rad | sin θ | cos θ | tan θ |
|---|---|---|---|---|
| 0 | 0 | 0 | 1 | 0 |
| 30 | π/6 | 1/2 | $\sqrt{3}/2$ | $\sqrt{3}/3$ |
| 45 | π/4 | $\sqrt{2}/2$ | $\sqrt{2}/2$ | 1 |
| 60 | π/3 | $\sqrt{3}/2$ | 1/2 | $\sqrt{3}$ |
| 90 | π/2 | 1 | 0 | $+\infty$ |

If $90° \le \theta \le 180°$, $\sin\theta = \sin(180° - \theta)$; $\cos\theta = -\cos(180° - \theta)$; $\tan\theta = -\tan(180° - \theta)$. If $180° \le \theta \le 270°$, $\sin\theta = -\sin(270° - \theta)$; $\cos\theta = -\cos(270° - \theta)$; $\tan\theta = \tan(270° - \theta)$. If $270° \le \theta \le 360°$, $\sin\theta = -\sin(360° - \theta)$; $\cos\theta = \cos(360° - \theta)$; $\tan\theta = -\tan(360° - \theta)$. The reciprocal properties may be used to find the values of the other functions.

If it is desired to find the angle when a function of it is given, the procedure is as follows: There will in general be two angles between 0° and 360° corresponding to the given value of the function.

| Given $a > 0$ | Find an acute angle $\theta_0$ such that | Required angles are |
|---|---|---|
| $\sin\theta = +a$ | $\sin\theta_0 = a$ | $\theta_0$ and $180° - \theta_0$ |
| $\cos\theta = +a$ | $\cos\theta_0 = a$ | $\theta_0$ and $360° - \theta_0$ |
| $\tan\theta = +a$ | $\tan\theta_0 = a$ | $\theta_0$ and $180° + \theta_0$ |
| $\sin\theta = -a$ | $\sin\theta_0 = a$ | $180° + \theta_0$ and $360° - \theta_0$ |
| $\cos\theta = -a$ | $\cos\theta_0 = a$ | $180° - \theta_0$ and $180° + \theta_0$ |
| $\tan\theta = -a$ | $\tan\theta_0 = a$ | $180° - \theta_0$ and $360° - \theta_0$ |

**Relations between Functions of a Single Angle** $\sec\theta = 1/\cos\theta$; $\csc\theta = 1/\sin\theta$, $\tan\theta = \sin\theta/\cos\theta = \sec\theta/\csc\theta = 1/\cot\theta$; $\sin^2\theta + \cos^2\theta = 1$; $1 + \tan^2\theta = \sec^2\theta$; $1 + \cot^2\theta = \csc^2\theta$. For $0 \le \theta \le 90°$ the following results hold:

$$\sin\theta = 2\sin\left(\frac{\theta}{2}\right)\cos\left(\frac{\theta}{2}\right)$$

and

$$\cos\theta = \cos^2\left(\frac{\theta}{2}\right) - \sin^2\left(\frac{\theta}{2}\right)$$

The cofunction property is very important. $\cos\theta = \sin(90° - \theta)$, $\sin\theta = \cos(90° - \theta)$, $\tan\theta = \cot(90° - \theta)$, $\cot\theta = \tan(90° - \theta)$, etc.

**Functions of Negative Angles** $\sin(-\theta) = -\sin\theta$, $\cos(-\theta) = \cos\theta$, $\tan(-\theta) = -\tan\theta$, $\sec(-\theta) = \sec\theta$, $\csc(-\theta) = -\csc\theta$, $\cot(-\theta) = -\cot\theta$.

**Identities**

***Sum and Difference Formulas*** Let $x, y$ be two angles. $\sin(x \pm y) = \sin x \cos y \pm \cos x \sin y$; $\cos(x \pm y) = \cos x \cos y \mp \sin x \sin y$; $\tan(x \pm y) = (\tan x \pm \tan y)/(1 \mp \tan x \tan y)$; $\sin x \pm \sin y = 2\sin\frac{1}{2}(x \pm y)\cos\frac{1}{2}(x \mp y)$; $\cos x + \cos y = 2\cos\frac{1}{2}(x+y)\cos\frac{1}{2}(x-y)$; $\cos x - \cos y = -2\sin\frac{1}{2}(x+y)\sin\frac{1}{2}(x-y)$; $\tan x \pm \tan y = [\sin(x \pm y)]/(\cos x \cos y)$; $\sin^2 x - \sin^2 y = \cos^2 y - \cos^2 x = \sin(x+y)\sin(x-y)$; $\cos^2 x - \sin^2 y = \cos^2 y - \sin^2 x = \cos(x+y) \times \cos(x-y)$; $\sin(45° + x) = \cos(45° - x)$; $\sin(45° - x) = \cos(45° + x)$; $\tan(45° \pm x) = \cot(45° \mp x)$.

***Multiple and Half-Angle Identities*** Let $x$ = angle, $\sin 2x = 2\sin x \cos x$; $\sin x = 2\sin\frac{1}{2}x \times \cos\frac{1}{2}x$; $\cos 2x = \cos^2 x - \sin^2 x = 1 - 2\sin^2 x = 2\cos^2 x - 1$. $\tan 2x = (2\tan x)/(1 - \tan^2 x)$; $\sin 3x = 3\sin x - 4\sin^3 x$; $\cos 3x = 4\cos^3 x - 3\cos x$. $\tan 3x = (3\tan x - \tan^3 x)/(1 - 3\tan^2 x)$; $\sin 4x = 4\sin x \cos x - 8\sin^3 x \cos x$; $\cos 4x = 8\cos^4 x - 8\cos^2 x + 1$.

$$\sin\left(\frac{x}{2}\right) = \sqrt{\tfrac{1}{2}(1 - \cos x)}$$

$$\cos\left(\frac{x}{2}\right) = \sqrt{\tfrac{1}{2}(1 + \cos x)}$$

$$\tan\left(\frac{x}{2}\right) = \sqrt{\frac{1-\cos x}{1+\cos x}} = \frac{\sin x}{1+\cos x} = \frac{1-\cos x}{\sin x}$$

## INVERSE TRIGONOMETRIC FUNCTIONS

Note that $y = \sin^{-1} x = \arcsin x$ is the angle $y$ whose sine is $x$.

***Example*** $y = \sin^{-1}(\frac{1}{2})$, $y$ is 30°.

The complete solution of the equation $x = \sin y$ is $y = (-1)^n \sin^{-1} x + n(180°)$, $-\pi/2 \le \sin^{-1} x \le \pi/2$ where $\sin^{-1} x$ is the principal value of the angle whose sine is $x$. The range of principal values of $\cos^{-1} x$ is $0 \le \cos^{-1} x \le \pi$ and $-\pi/2 \le \tan^{-1} x \le \pi/2$. If these restrictions are allowed to hold, the following formulas result:

$$\sin^{-1} x = \cos^{-1}\sqrt{1-x^2} = \tan^{-1}\frac{x}{\sqrt{1-x^2}} = \cot^{-1}\frac{\sqrt{1-x^2}}{x}$$

$$= \sec^{-1}\frac{1}{\sqrt{1-x^2}} = \csc^{-1}\frac{1}{x} = \frac{\pi}{2} - \cos^{-1} x$$

$$\cos^{-1} x = \sin^{-1}\sqrt{1-x^2} = \tan^{-1}\frac{\sqrt{1-x^2}}{x}$$

$$= \cot^{-1}\frac{x}{\sqrt{1-x^2}} = \sec^{-1}\frac{1}{x}$$

$$= \csc^{-1}\frac{1}{\sqrt{1-x^2}} = \frac{\pi}{2} - \sin^{-1} x$$

$$\tan^{-1} x = \sin^{-1}\frac{x}{\sqrt{1-x^2}} = \cos^{-1}\frac{1}{\sqrt{1+x^2}}$$

$$= \cot^{-1}\frac{1}{x} = \sec^{-1}\sqrt{1+x^2} = \csc^{-1}\frac{\sqrt{1+x^2}}{x}$$

## RELATIONS BETWEEN ANGLES AND SIDES OF TRIANGLES

**Solutions of Triangles** (Fig. 3-40) Let $a$, $b$, and $c$ denote the sides and $\alpha$, $\beta$, and $\gamma$ the angles opposite the sides in the triangle. Let $2s = a + b + c$, $A$ = area, $r$ = radius of the inscribed circle, $R$ = radius of the circumscribed circle, and $h$ = altitude. In any triangle $\alpha + \beta + \gamma = 180°$.

**Law of Sines** $\sin\alpha/a = \sin\beta/b = \sin\gamma/c = 1/(2R)$.

**Law of Tangents**

$$\frac{a+b}{a-b} = \frac{\tan\frac{1}{2}(\alpha+\beta)}{\tan\frac{1}{2}(\alpha-\beta)}; \quad \frac{b+c}{b-c} = \frac{\tan\frac{1}{2}(\beta+\gamma)}{\tan\frac{1}{2}(\beta-\gamma)}; \quad \frac{a+c}{a-c} = \frac{\tan\frac{1}{2}(\alpha+\gamma)}{\tan\frac{1}{2}(\alpha-\gamma)}$$

**Law of Cosines** $a^2 = b^2 + c^2 - 2bc\cos\alpha$; $b^2 = a^2 + c^2 - 2ac\cos\beta$; $c^2 = a^2 + b^2 - 2ab\cos\gamma$.

More formulas can be generated by replacing $a$ by $b$, $b$ by $c$, $c$ by $a$, $\alpha$ by $\beta$, $\beta$ by $\gamma$, and $\gamma$ by $\alpha$.

$$A = \frac{1}{2}bh = \frac{1}{2}ab\sin\gamma = \sqrt{s(s-a)(s-b)(s-c)} = rs$$

where

$$r = \sqrt{\frac{(s-a)(s-b)(s-c)}{s}}$$

$$R = a/(2\sin\alpha) = abc/4A \qquad h = c\sin\alpha = a\sin\gamma = 2rs/b$$

**Right Triangle** (Fig. 3-41) Given one side and any acute angle $\alpha$ or any two sides, the remaining parts can be obtained from the following formulas:

$$a = \sqrt{(c+b)(c-b)} = c\sin\alpha = b\tan\alpha$$

$$b = \sqrt{(c+a)(c-a)} = c\cos\alpha = a\cot\alpha$$

$$c = \sqrt{a^2+b^2} \qquad \sin\alpha = \frac{a}{c} \qquad \cos\alpha = \frac{b}{c} \qquad \tan\alpha = \frac{a}{b} \qquad \beta = 90° - \alpha$$

$$A = \frac{1}{2}ab = \frac{a^2}{2\tan\alpha} = \frac{b^2\tan\alpha}{2} = \frac{c^2\sin 2\alpha}{4}$$

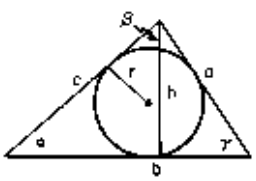

**FIG. 3-40** Triangle.

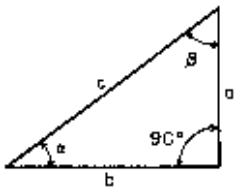

**FIG. 3-41** Right triangle.

## HYPERBOLIC TRIGONOMETRY

The hyperbolic functions are certain combinations of exponentials $e^x$ and $e^{-x}$.

$$\cosh x = \frac{e^x + e^{-x}}{2};\ \sinh x = \frac{e^x - e^{-x}}{2};\ \tanh x = \frac{\sinh x}{\cosh x} = \frac{e^x - e^{-x}}{e^x + e^{-x}}$$

$$\coth x = \frac{e^x + e^x}{e^x - e^{-x}} = \frac{1}{\tanh x} = \frac{\cosh x}{\sinh x};\ \operatorname{sech} x = \frac{1}{\cosh x} = \frac{2}{e^x + e^{-x}};$$

$$\operatorname{csch} x = \frac{1}{\sinh x} = \frac{2}{e^x - e^{-x}}$$

**Fundamental Relationships** $\sinh x + \cosh x = e^x$; $\cosh x - \sinh x = e^{-x}$; $\cosh^2 x - \sinh^2 x = 1$; $\operatorname{sech}^2 x + \tanh^2 x = 1$; $\coth^2 x - \operatorname{csch}^2 x = 1$; $\sinh 2x = 2 \sinh x \cosh x$; $\cosh 2x = \cosh^2 x + \sinh^2 x = 1 + 2 \sinh^2 x = 2 \cosh^2 x - 1$. $\tanh 2x = (2 \tanh x)/(1 + \tanh^2 x)$; $\sinh (x \pm y) = \sinh x \cosh y \pm \cosh x \sinh y$; $\cosh (x \pm y) = \cosh x \cosh y \pm \sinh x \sinh y$; $2 \sinh^2 x/2 = \cosh x - 1$; $2 \cosh^2 x/2 = \cosh x + 1$; $\sinh (-x) = -\sinh x$; $\cosh (-x) = \cosh x$; $\tanh (-x) = -\tanh x$.

When $u = a \cosh x$ and $v = a \sinh x$, then $u^2 - v^2 = a^2$, which is the equation for a hyperbola. In other words, the hyperbolic functions in the parametric equations $u = a \cosh x$ and $v = a \sinh x$ have the same relation to the hyperbola $u^2 - v^2 = a^2$ that the equations $u = a \cos \theta$ and $v = a \sin \theta$ have to the circle $u^2 + v^2 = a^2$.

**Inverse Hyperbolic Functions** If $x = \sinh y$, then $y$ is the inverse hyperbolic sine of $x$, written as $y = \sinh^{-1} x$ or $\operatorname{arcsinh} x$. $\sinh^{-1} x = \ln_e (x + \sqrt{x^2 + 1})$

$$\cosh^{-1} x = \ln_e (x + \sqrt{x^2 - 1});\ \tanh^{-1} x = \frac{1}{2} \ln_e \frac{1 + x}{1 - x};$$

$$\coth^{-1} x = \frac{1}{2} \ln_e \frac{x + 1}{x - 1};\ \operatorname{sech}^{-1} x = \ln_e \left( \frac{1 + \sqrt{1 - x^2}}{x} \right);$$

$$\operatorname{csch}^{-1} = \ln_e \left( \frac{1 + \sqrt{1 + x^2}}{x} \right)$$

**Magnitude of the Hyperbolic Functions** $\cosh x \geq 1$ with equality only for $x = 0$; $-\infty < \sinh x < \infty$; $-1 < \tanh x < 1$. $\cosh x \sim e^x/2$ as $x \to \infty$; $\sinh x \to e^x/2$ as $x \to \infty$.

## APPROXIMATIONS FOR TRIGONOMETRIC FUNCTIONS

For small values of $\theta$ ($\theta$ measured in radians) $\sin \theta \approx \theta$, $\tan \theta \approx \theta$; $\cos \theta \approx 1 - \theta^2/2$.

# DIFFERENTIAL AND INTEGRAL CALCULUS

**REFERENCES**: Larson, R., and B. H. Edwards, *Calculus*, 10th ed., Brooks/Cole, Pacific Grove, Calif., 2013.

## DIFFERENTIAL CALCULUS

**Limits** The limit of function $f(x)$ as $x$ approaches $a$ ($a$ is finite or else $x$ is said to increase without bound) is the number $N$.

$$\lim_{x \to a} f(x) = N$$

This states that $f(x)$ can be calculated as close to $N$ as desirable by making $x$ sufficiently close to $a$. This does not put any restriction on $f(x)$ when $x = a$. Alternatively, for any given positive number $\varepsilon$, a number $\delta$ can be found such that $0 < |a - x| < \delta$ implies that $|N - f(x)| < \varepsilon$.

The following operations with limits (when they exist) are valid:

$$\lim_{x \to a} bf(x) = b \lim_{x \to a} f(x)$$

$$\lim_{x \to a} [f(x) + g(x)] = \lim_{x \to a} f(x) + \lim_{x \to a} g(x)$$

$$\lim_{x \to a} [f(x)\, g(x)] = \lim_{x \to a} f(x) \cdot \lim_{x \to a} g(x)$$

$$\lim_{x \to a} \frac{f(x)}{g(x)} = \frac{\lim_{x \to a} f(x)}{\lim_{x \to a} g(x)} \text{ if } \lim_{x \to a} g(x) \neq 0$$

See "Indeterminant Forms" below when $g(a) = 0$.

**Continuity** A function $f(x)$ is continuous at the point $x = a$ if

$$\lim_{h \to 0} [f(a + h) - f(a)] = 0$$

Rigorously, it is stated that $f(x)$ is continuous at $x = a$ if for any positive $\varepsilon$ there exists a $\delta > 0$ such that $|f(a + h) - f(a)| < \varepsilon$ for all $x$ with $|x - a| < \delta$. For example, the function $(\sin x)/x$ is not continuous at $x = 0$ and therefore is said to be *discontinuous*. Discontinuities are classified into three types:

| | | |
|---|---|---|
| 1. Removable | $y = (\sin x)/x$ | at $x = 0$ |
| 2. Infinite | $y = 1/x$ | at $x = 0$ |
| 3. Jump | $y = 10/(1 + e^{1/x})$ | at $x = 0^+$ $y = 0^+$ |
| | $x = 0$ $y = 0$ | |
| | $x = 0^-$ $y = 10$ | |

**Derivative** The function $f(x)$ has a derivative at $x = a$, denoted as $f'(a)$, if

$$\lim_{h \to 0} \frac{f(a + h) - f(a)}{h}$$

exists. This implies continuity at $x = a$. However, a function may be continuous but not have a derivative. The derivative function is

$$f'(x) = \frac{df}{dx} = \lim_{h \to 0} \frac{f(x + h) - f(x)}{h}$$

***Differentiation*** Define $\Delta y = f(x + \Delta x) - f(x)$. Then dividing by $\Delta x$ gives

$$\frac{\Delta y}{\Delta x} = \frac{f(x + \Delta x) - f(x)}{\Delta x}$$

Call $$\lim_{\Delta x \to 0} \frac{\Delta y}{\Delta x} = \frac{dy}{dx}$$

Then $$\frac{dy}{dx} = \lim_{\Delta x \to 0} \frac{f(x + \Delta x) - f(x)}{\Delta x}$$

***Differential Operations*** The following differential operations are valid: $f, g, \ldots$ are differentiable functions of $x$; $c$ and $n$ are constants; $e$ is the base of the natural logarithms.

$$\frac{dc}{dx} = 0 \tag{3-1}$$

$$\frac{dx}{dx} = 1 \tag{3-2}$$

$$\frac{d}{dx}(f + g) = \frac{df}{dx} + \frac{dg}{dx} \tag{3-3}$$

$$\frac{d}{dx}(f \times g) = f \frac{dg}{dx} + g \frac{df}{dx} \tag{3-4}$$

$$\frac{dy}{dx} = \frac{1}{dx/dy} \quad \text{if} \quad \frac{dx}{dy} \neq 0 \tag{3-5}$$

$$\frac{d}{dx} f^n = n f^{n-1} \frac{df}{dx} \tag{3-6}$$

$$\frac{d}{dx}\left( \frac{f}{g} \right) = \frac{g(df/dx) - f(dg/dx)}{g^2} \tag{3-7}$$

$$\frac{df}{dx} = \frac{df}{dv} \times \frac{dv}{dx} \text{ (chain rule)} \tag{3-8}$$

$$\frac{df^g}{dx} = g f^{g-1}\frac{df}{dx} + f^g \ln f \frac{dg}{dx} \tag{3-9}$$

$$\frac{da^x}{dx} = (\ln a)\, a^x \tag{3-10}$$

***Example*** Derive $dy/dx$ for $x^2 + y^3 = x + xy + A$.

Here
$$\frac{d}{dx}x^2 + \frac{d}{dx}y^3 = \frac{d}{dx}x + \frac{d}{dx}xy + \frac{d}{dx}A$$
$$2x + 3y^2\frac{dy}{dx} = 1 + y + x\frac{dy}{dx} + 0$$

by the rules in Eqs. (3-6), (3-6), (3-2), (3-4), and (3-1), respectively.

Thus
$$\frac{dy}{dx} = \frac{2x - 1 - y}{x - 3y^2}$$

***Differentials***

$$de^x = e^x\, dx \tag{3-11}$$
$$d(a^x) = a^x \ln a\, dx \tag{3-12}$$
$$d\ln x = (1/x)\, dx \tag{3-13}$$
$$d\log x = (\log e/x)\, dx \tag{3-14}$$
$$d\sin x = \cos x\, dx \tag{3-15}$$
$$d\cos x = -\sin x\, dx \tag{3-16}$$
$$d\tan x = \sec^2 x\, dx \tag{3-17}$$
$$d\cot x = -\csc^2 x\, dx \tag{3-18}$$
$$d\sec x = \tan x \sec x\, dx \tag{3-19}$$
$$d\csc x = -\cot x \csc x\, dx \tag{3-20}$$
$$d\sin^{-1} x = (1 - x^2)^{-1/2}\, dx \tag{3-21}$$
$$d\cos^{-1} x = -(1 - x^2)^{-1/2}\, dx \tag{3-22}$$
$$d\tan^{-1} x = (1 + x^2)^{-1}\, dx \tag{3-23}$$
$$d\cot^{-1} x = -(1 + x^2)^{-1}\, dx \tag{3-24}$$
$$d\sec^{-1} x = x^{-1}(x^2 - 1)^{-1/2}\, dx \tag{3-25}$$
$$d\csc^{-1} x = -x^{-1}(x^2 - 1)^{-1/2}\, dx \tag{3-26}$$
$$d\sinh x = \cosh x\, dx \tag{3-27}$$
$$d\cosh x = \sinh x\, dx \tag{3-28}$$
$$d\tanh x = \operatorname{sech}^2 x\, dx \tag{3-29}$$
$$d\coth x = -\operatorname{csch}^2 x\, dx \tag{3-30}$$
$$d\operatorname{sech} x = -\operatorname{sech} x \tanh x\, dx \tag{3-31}$$
$$d\operatorname{csch} x = -\operatorname{csch} x \coth x\, dx \tag{3-32}$$
$$d\sinh^{-1} x = (x^2 + 1)^{-1/2}\, dx \tag{3-33}$$
$$d\cosh^{-1} = (x^2 - 1)^{-1/2}\, dx \tag{3-34}$$
$$d\tanh^{-1} x = (1 - x^2)^{-1}\, dx \tag{3-35}$$
$$d\coth^{-1} x = -(x^2 - 1)^{-1}\, dx \tag{3-36}$$
$$d\operatorname{sech}^{-1} x = -(1/x)(1 - x^2)^{-1/2}\, dx \tag{3-37}$$
$$d\operatorname{csch}^{-1} x = -x^{-1}(x^2 + 1)^{-1/2}\, dx \tag{3-38}$$

***Example*** Find $dy/dx$ for $y = \sqrt{x}\cos(1 - x^2)$. Using

$$\frac{dy}{dx} = \sqrt{x}\frac{d}{dx}\cos(1 - x^2) + \cos(1 - x^2)\frac{d}{dx}\sqrt{x} \tag{3-4}$$

$$\frac{d}{dx}\cos(1 - x^2) = -\sin(1 - x^2)\frac{d}{dx}(1 - x^2) \tag{3-16}$$

$$= -\sin(1 - x^2)(0 - 2x) \tag{3-1), (3-6}$$

$$\frac{d\sqrt{x}}{dx} = \frac{1}{2}x^{-1/2}$$
$$\frac{dy}{dx} = 2x^{3/2}\sin(1 - x^2) + \frac{1}{2}x^{-1/2}\cos(1 - x^2) \tag{3-6}$$

***Example*** Find the derivative of $\tan x$ with respect to $\sin x$.
Let

$$\upsilon = \sin x$$
$$y = \tan x$$

Then,

Using
$$\frac{d\tan x}{d\sin x} = \frac{dy}{d\upsilon} = \frac{dy}{dx}\frac{dx}{d\upsilon} \tag{3-8}$$

$$= \frac{d\tan x}{dx}\frac{1}{\dfrac{d\sin x}{dx}} \tag{3-5}$$

$$= \sec^2 x / \cos x \tag{3-17), (3-15}$$

If the functions and derivatives are known only numerically at some point, the same formulas may be used.

***Higher Differentials*** The first derivative of $f(x)$ with respect to $x$ is denoted by $f'$ or $df/dx$. The derivative of the first derivative is called the *second derivative* of $f(x)$ with respect to $x$ and is denoted by $f''$, $f^{(2)}$, or $d^2f/dx^2$; and similarly for the higher-order derivatives.

***Example*** Given $f(x) = 3x^3 + 2x + 1$, calculate all derivative values.

$$\frac{df(x)}{dx} = 9x^2 + 2, \quad \frac{d^2f(x)}{dx^2} = 18x, \quad \frac{d^3f(x)}{dx^3} = 18, \quad \frac{d^nf(x)}{dx^n} = 0 \quad \text{for } n \geq 4$$

If $f'(x) > 0$ on $(a, b)$, then $f$ is increasing on $(a, b)$. If $f'(x) < 0$ on $(a, b)$, then $f$ is decreasing on $(a, b)$. The graph of a function $y = f(x)$ is concave up if $f'$ is increasing on $(a, b)$; it is concave down if $f'$ is decreasing on $(a, b)$. If $f''(x)$ exists on $(a, b)$ and if $f''(x) > 0$, then $f$ is concave up on $(a, b)$. If $f''(x) < 0$, then $f$ is concave down on $(a, b)$.

An *inflection point* is a point at which a function changes the direction of its concavity.

**Indeterminate Forms: L'Hôpital's Theorem** Forms of the type 0/0, $\infty/\infty$, $0 \times \infty$, etc., are called *indeterminates*. To find the limiting values that the corresponding functions approach, L'Hôpital's theorem is useful: If two functions $f(x)$ and $g(x)$ both become zero at $x = a$, then the limit of their quotient is equal to the limit of the quotient of their separate derivatives, if the limit exists, or is $+\infty$ or $-\infty$.

***Example*** Find $\lim_{n\to 0}\dfrac{\sin x}{x}$.

Here
$$\lim_{x\to 0}\frac{\sin x}{x} = \lim_{x\to 0}\frac{d\sin x}{dx} \Big/ \lim_{x\to 0}\frac{dx}{dx} = \lim_{x\to 0}\frac{\cos x}{1} = 1$$

***Example*** Find $\lim_{x\to\infty} x^3 e^{-x}$.

$$\lim_{x\to\infty} x^3 e^{-x} = \lim_{x\to\infty}\frac{x^3}{e^x} = \lim_{x\to\infty}\frac{6}{e^x} = 0$$

***Example*** Find $\lim_{x\to 0}(1 - x)^{1/x}$.

Let $\quad y = (1 - x)^{1/x} \qquad \ln y = (1/x)\ln(1 - x)$

Then

$$\lim_{x\to 0}(\ln y) = \lim_{x\to 0}\frac{\ln(1 - x)}{x} = \frac{\lim_{x\to 0}\ln(1 - x)}{\lim_{x\to 0} x}$$
$$= \frac{d[\ln(1 - x)]/dx\big|_{x=0}}{dx/dx\big|_{x=0}} = \frac{1}{1 - x}(-1)\Big|_{x=0} = -1$$

Therefore, $\quad \lim_{x\to 0} y = e^{-1}$

**Partial Derivative** The abbreviation $z = f(x, y)$ means that $z$ is a function of the two variables $x$ and $y$. The derivative of $z$ with respect to $x$, treating $y$ as a constant, is called the *partial derivative* with respect to $x$ and is usually denoted as $\partial z/\partial x$ or $\partial f(x, y)/\partial x$ or simply $f_x$. Partial differentiation,

like full differentiation, is quite simple to apply. Conversely, the solution of partial differential equations is appreciably more difficult than that of differential equations.

***Example*** Find $\partial z/\partial x$ and $\partial z/\partial y$ for $z = ye^{x^2} + xe^y$.

$$\frac{\partial z}{\partial x} = y\frac{\partial e^{x^2}}{\partial x} + e^y\frac{\partial x}{\partial x} = 2xye^{x^2} + e^y$$

$$\frac{\partial z}{\partial y} = e^{x^2}\frac{\partial y}{\partial y} + x\frac{\partial e^y}{\partial y} = e^{x^2} + xe^y$$

***Order of Differentiation*** It is generally true that the order of differentiation is immaterial for any number of differentiations or variables, provided the function and the appropriate derivatives are continuous. For $z = f(x, y)$ it follows that

$$\frac{\partial^3 f}{\partial y^2\,\partial x} = \frac{\partial^3 f}{\partial y\,\partial x\,\partial y} = \frac{\partial^3 f}{\partial x\,\partial y^2}$$

***General Form for Partial Differentiation***

1. Given $f(x, y) = 0$ and $x = g(t), y = h(t)$.

Then $$\frac{df}{dt} = \frac{\partial f}{\partial x}\frac{dx}{dt} + \frac{\partial f}{\partial y}\frac{dy}{dt}$$

$$\frac{d^2 f}{dt^2} = \frac{\partial^2 f}{\partial x^2}\left(\frac{dx}{dt}\right)^2 + 2\frac{\partial^2 f}{\partial x\,\partial y}\frac{dx}{dt}\frac{dy}{dt} + \frac{\partial^2 f}{\partial y^2}\left(\frac{dy}{dt}\right)^2 + \frac{\partial f}{\partial x}\frac{d^2x}{dt^2} + \frac{\partial f}{\partial y}\frac{d^2y}{dt^2}$$

***Example*** Find $df/dt$ for $f = xy$, $x = \rho \sin t$, and $y = \rho \cos t$.

$$\frac{df}{dt} = \frac{\partial(xy)}{\partial x}\left(\frac{d\,\rho\sin t}{dt}\right) + \frac{\partial(xy)}{\partial y}\left(\frac{d\,\rho\cos t}{dt}\right)$$

$$= y(\rho\cos t) + x(-\rho\sin t)$$

$$= \rho^2\cos^2 t - \rho^2\sin^2 t$$

2. Given $f(x, y) = 0$ and $x = g(t, s), y = h(t, s)$.

Then $$\frac{\partial f}{\partial t} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial t} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial t}$$

$$\frac{\partial f}{\partial s} = \frac{\partial f}{\partial x}\frac{\partial x}{\partial s} + \frac{\partial f}{\partial y}\frac{\partial y}{\partial s}$$

***Differentiation of Composite Function***

***Rule 1.*** Given $f(x, y) = 0$, then $\dfrac{dy}{dx} = -\dfrac{\partial f/\partial x}{\partial f/\partial y}\left(\dfrac{\partial f}{\partial y} \neq 0\right)$.

***Rule 2.*** Given $f(u) = 0$ where $u = g(x)$, then

$$\frac{df}{dx} = f'(u)\frac{du}{dx}$$

$$\frac{d^2 f}{dx^2} = f''(u)\left(\frac{du}{dx}\right)^2 + f'(u)\frac{d^2u}{dx^2}$$

***Rule 3.*** Given $f(u) = 0$ where $u = g(x, y)$, then

$$\frac{\partial^2 f}{\partial x^2} = f''\left(\frac{\partial u}{\partial x}\right)^2 + f'\frac{\partial^2 u}{\partial x^2}$$

$$\frac{\partial^2 f}{\partial x\,\partial y} = f''\frac{\partial u}{\partial x}\frac{\partial u}{\partial y} + f'\frac{\partial^2 u}{\partial x\,\partial y}$$

$$\frac{\partial^2 f}{\partial y^2} = f''\left(\frac{\partial u}{\partial y}\right)^2 + f'\frac{\partial^2 u}{\partial y^2}$$

## MULTIVARIABLE CALCULUS APPLIED TO THERMODYNAMICS

Many of the functional relationships needed in thermodynamics are direct applications of the rules of multivariable calculus. This section reviews those rules in the context of the needs of thermodynamics. These ideas were expounded in one of the classic books on chemical engineering thermodynamics (see Hougen, O. A., et al., Part II, "Thermodynamics," in *Chemical Process Principles*, 2d ed., Wiley, New York, 1959).

**State Functions** State functions depend only on the state of the system, not on history or how one got there. If $z$ is a function of two variables $x$ and $y$, then $z(x, y)$ is a state function, since $z$ is known once $x$ and $y$ are specified. The differential of $z$ is

$$dz = M\,dx + N\,dy$$

The line integral

$$\int_c (M\,dx + N\,dy)$$

is independent of the path in $xy$ space if and only if

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x} \tag{3-39}$$

and $dz$ is called an exact differential. The total differential can be written as

$$dz = \left(\frac{\partial z}{\partial x}\right)_y dx + \left(\frac{\partial z}{\partial y}\right)_x dy \tag{3-40}$$

and thus the following application of Eq. (3-39) guarantees path independence.

$$\frac{\partial}{\partial y}\left(\frac{\partial z}{\partial x}\right)_y = \frac{\partial}{\partial x}\left(\frac{\partial z}{\partial y}\right)_x$$

or $$\frac{\partial^2 z}{\partial y\,\partial x} = \frac{\partial^2 z}{\partial x\,\partial y} \tag{3-41}$$

***Example*** Suppose $z$ is constant and apply Eq. (3-40).

$$\left[0 = \left(\frac{\partial z}{\partial x}\right)_y dx + \left(\frac{\partial z}{\partial y}\right)_x dy\right]_z$$

Rearrangement gives the triple product rule

$$\left(\frac{\partial z}{\partial x}\right)_y = -\left(\frac{\partial y}{\partial x}\right)_z\left(\frac{\partial z}{\partial y}\right)_x = -\frac{(\partial y/\partial x)_z}{(\partial y/\partial z)_x} \text{ or } \left(\frac{\partial z}{\partial x}\right)_y\left(\frac{\partial x}{\partial y}\right)_z\left(\frac{\partial y}{\partial z}\right)_x = -1 \tag{3-42}$$

Alternatively, divide Eq. (3-40) by $dy$ when holding some other variable $w$ constant to obtain

$$\left(\frac{\partial z}{\partial y}\right)_w = \left(\frac{\partial z}{\partial x}\right)_y\left(\frac{\partial x}{\partial y}\right)_w + \left(\frac{\partial z}{\partial y}\right)_x \tag{3-43}$$

Also divide both numerator and denominator of a partial derivative by $dw$ while holding a variable $y$ constant to get the chain rule.

$$\left(\frac{\partial z}{\partial x}\right)_y = \frac{(\partial z/\partial w)_y}{(\partial x/\partial w)_y} = \left(\frac{\partial z}{\partial w}\right)_y\left(\frac{\partial w}{\partial x}\right)_y \tag{3-44}$$

**Thermodynamic State Functions** In thermodynamics, the state functions include the internal energy $U$, enthalpy $H$, and Helmholtz and Gibbs free energies $A$ and $G$, respectively, defined as follows:

$$H = U + PV$$

$$A = U - TS$$

$$G = H - TS = U + PV - TS = A + PV$$

where $S$ is the entropy, $T$ the absolute temperature, $P$ the pressure, and $V$ the volume. These are also state functions, in that the entropy is specified

once two variables (such as $T$ and $P$) are specified, for example. Likewise, $V$ is specified once $T$ and $P$ are specified; it is therefore a state function.

In an open system, extensive properties, such as the total internal energy, are functions of two thermodynamic variables plus the mass or moles of each component. The mathematical derivations below are for a single-component system of constant mass. They are applicable when the mass stays constant, i.e., in an intensive system (or else an additional variable for moles $N$ must be added). However, the relations between the thermodynamic variables can be regarded as internal energy per moles in a closed system, or at a point in an open system. The formulas illustrate the use of calculus in thermodynamics.

If a process is reversible and only $P$-$V$ work is done, the first law and differentials can be expressed as follows:

$$dU = T\,dS - P\,dV \tag{3-45}$$

$$dH = T\,dS + V\,dP \tag{3-46}$$

$$dA = -S\,dT - P\,dV \tag{3-47}$$

$$dG = -S\,dT + V\,dP \tag{3-48}$$

Alternatively, if the internal energy is considered a function of $S$ and $V$, then the differential is

$$dU = \left(\frac{\partial U}{\partial S}\right)_V dS + \left(\frac{\partial U}{\partial V}\right)_S dV$$

This is the equivalent of Eq. (3-43) and gives the following definitions:

$$T = \left(\frac{\partial U}{\partial S}\right)_V, \quad P = -\left(\frac{\partial U}{\partial V}\right)_S$$

Since the internal energy is a state function, Eq. (3-44) must be satisfied.

$$\frac{\partial^2 U}{\partial V\,\partial S} = \frac{\partial^2 U}{\partial S\,\partial V}$$

This is

$$\left(\frac{\partial T}{\partial V}\right)_S = -\left(\frac{\partial P}{\partial S}\right)_V$$

This is one of the Maxwell relations, and the other Maxwell relations can be derived in a similar fashion by applying Eq. (3-41). See Sec. 4, Thermodynamics, "Constant-Composition Systems."

**Partial Derivatives of Intensive Thermodynamic Functions** The various partial derivatives of the thermodynamic functions can be classified into six groups. In the general formulas below, the variables $U$, $H$, $A$, $G$, and $S$ are denoted by Greek letters (these can be extensive properties), while the variables $V$, $T$, and $P$ are denoted by Latin letters ($T$ and $P$ can only be intensive properties).

***Type I*** (3 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial a}{\partial b}\right)_c \qquad \text{specific: } \left(\frac{\partial P}{\partial T}\right)_V$$

Equation (3-42) gives

$$\left(\frac{\partial P}{\partial T}\right)_V = -\left(\frac{\partial V}{\partial T}\right)_P \left(\frac{\partial P}{\partial V}\right)_T = -\frac{(\partial V/\partial T)_P}{(\partial V/\partial P)_T}$$

***Type II*** (30 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial \alpha}{\partial b}\right)_c \qquad \text{specific: } \left(\frac{\partial G}{\partial T}\right)_V$$

The differential for $G$ is from Eq. (3-48) or Eq. (3-43) with $x \to P$:

$$\left(\frac{\partial G}{\partial T}\right)_V = -S + V\left(\frac{\partial P}{\partial T}\right)_V$$

Using the other equations for $U$, $H$, $A$, or $S$ gives the other possibilities.

***Type III*** (15 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial a}{\partial b}\right)_\alpha \qquad \text{specific: } \left(\frac{\partial V}{\partial T}\right)_S$$

First evaluate the derivative, using Eq. (3-45).

$$\left(\frac{\partial V}{\partial T}\right)_S = -\left(\frac{\partial S}{\partial T}\right)_V \left(\frac{\partial V}{\partial S}\right)_T = -\frac{(\partial S/\partial T)_V}{(\partial S/\partial V)_T}$$

Then evaluate the numerator and denominator as type II derivatives. Use Eq. (3-45) and Eq. (3-41) to get $(\partial S/\partial T)_V = C_v/T$. Use Eqs. (3-47) and (3-41) to get the Maxwell relation $(\partial P/\partial T)_V = (\partial S/\partial V)_T$. Finally use Eq. (3-42).

$$\left(\frac{\partial V}{\partial T}\right)_S = -\frac{\dfrac{C_v}{T}}{-\left(\dfrac{\partial V}{\partial T}\right)_P \left(\dfrac{\partial P}{\partial V}\right)_T} = \frac{C_v}{T}\frac{\left(\dfrac{\partial V}{\partial P}\right)_T}{\left(\dfrac{\partial V}{\partial T}\right)_P}$$

These derivatives are of importance for reversible, adiabatic processes (such as in an ideal turbine or compressor), since then the entropy is constant. An example is the Joule-Thomson coefficient for constant $H$.

$$\left(\frac{\partial T}{\partial P}\right)_H = \frac{1}{C_p}\left[-V + T\left(\frac{\partial V}{\partial T}\right)_P\right]$$

***Type IV*** (30 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial \alpha}{\partial \beta}\right)_c \qquad \text{specific: } \left(\frac{\partial G}{\partial A}\right)_p$$

Use Eq. (3-47) to introduce a new variable $T$.

$$\left(\frac{\partial G}{\partial A}\right)_p = \left(\frac{\partial G}{\partial T}\right)_p \left(\frac{\partial T}{\partial A}\right)_p = \frac{(\partial G/\partial T)_P}{(\partial A/\partial T)_P}$$

This operation has created two type II derivatives; using the differential Eqs. (3-47) and (3-48), we obtain

$$\left(\frac{\partial G}{\partial A}\right)_p = \frac{S}{S + P\,(\partial V/\partial T)_P}$$

***Type V*** (60 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial \alpha}{\partial b}\right)_\beta \qquad \text{specific: } \left(\frac{\partial G}{\partial P}\right)_A$$

Start from the differential for $dG$. Then we get

$$\left(\frac{\partial G}{\partial P}\right)_A = -S\left(\frac{\partial T}{\partial P}\right)_A + V$$

The derivative is type III and can be evaluated by using Eq. (3-42).

$$\left(\frac{\partial G}{\partial P}\right)_A = S\frac{(\partial A/\partial P)_T}{(\partial A/\partial T)_P} + V$$

The two type II derivatives are then evaluated using the differential Eq. (3-47).

$$\left(\frac{\partial G}{\partial P}\right)_A = \frac{SP\,(\partial V/\partial P)_T}{S + P\,(\partial V/\partial T)_P} + V$$

These derivatives are also of interest for free expansions or isentropic changes.

***Type VI*** (30 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial \alpha}{\partial \beta}\right)_\gamma \qquad \text{specific: } \left(\frac{\partial G}{\partial A}\right)_H$$

We use Eq. (3-44) to obtain two type V derivatives.

$$\left(\frac{\partial G}{\partial A}\right)_H = \frac{(\partial G/\partial T)_H}{(\partial A/\partial T)_H}$$

These can then be evaluated using the procedures for type V derivatives.

## INTEGRAL CALCULUS

**Indefinite Integral** If $f'(x)$ is the derivative of $f(x)$, an antiderivative of $f'(x)$ is $f(x)$. Symbolically, the indefinite integral of $f'(x)$ is

$$\int f'(x)\,dx = f(x) + c$$

where $c$ is an arbitrary constant to be determined by the problem. By virtue of the known formulas for differentiation, the following relationships hold ($a$ is a constant):

$$\int (du + d\upsilon + dw) = \int du + \int d\upsilon + \int dw \tag{3-49}$$

$$\int a\,d\upsilon = a\int d\upsilon \tag{3-50}$$

$$\int \upsilon^n\,d\upsilon = \frac{\upsilon^{n+1}}{n+1} + c \qquad (n \neq -1) \tag{3-51}$$

$$\int \frac{d\upsilon}{\upsilon} = \ln|\upsilon| + c \tag{3-52}$$

$$\int a^\upsilon\,d\upsilon = \frac{a^\upsilon}{\ln a} + c \tag{3-53}$$

$$\int e^\upsilon\,d\upsilon = e^\upsilon + c \tag{3-54}$$

$$\int \sin\upsilon\,d\upsilon = -\cos\upsilon + c \tag{3-55}$$

$$\int \cos\upsilon\,d\upsilon = \sin\upsilon + c \tag{3-56}$$

Other integrals can be found at en.wikipedia.org/wiki/Lists_of_integrals.

***Example*** Find $\int (3x^2 + e^x - 10)\,dx$ using Eq. (3-49).

$$\int (3x^2 + e^x - 10)\,dx = 3\int x^2\,dx + \int e^x\,dx - 10\int dx = x^3 + e^x - 10x + c$$

***Example: Constant of Integration*** By definition the derivative of $x^3$ is $3x^2$, and $x^3$ is therefore the integral of $3x^2$. However, if $f = x^3 + 10$, it follows that $f' = 3x^2$, and $x^3 + 10$ is therefore also the integral of $3x^2$. For this reason the constant $c$ in $\int 3x^2\,dx = x^3 + c$ must be determined by the problem conditions, i.e., the value of $f$ for a specified $x$.

**Methods of Integration** In practice it is rare when generally encountered functions can be directly integrated. For example, the integrand in $\int \sqrt{\sin x}\,dx$ which appears quite simple has no elementary function whose derivative is $\sqrt{\sin x}$. In general, there is no explicit way of determining whether a particular function can be integrated into an elementary form. When they do not exist or cannot be found either from tabled integration formulas or directly, the only recourse is series expansion, as illustrated later. Indefinite integrals cannot be solved numerically unless they are redefined as definite integrals (see "Definite Integral"), that is, $F(x) = \int f(x)\,dx$ is indefinite, whereas $F(x) = \int_a^x f(t)\,dt$ is definite.

***Direct Formula*** Many integrals can be solved by transformation in the integrand to one of the forms given previously.

***Example*** Find $\int x^2\sqrt{3x^3 + 10}\,dx$. Let $\upsilon = 3x^3 + 10$ for which $d\upsilon = 9x^2\,dx$. Thus

$$\begin{aligned}\int x^2\sqrt{3x^3+10}\,dx &= \int (3x^3+10)^{1/2}(x^2\,dx)\\ &= \frac{1}{9}\int (3x^3+10)^{1/2}(9x^2\,dx) = \frac{1}{9}\int \upsilon^{1/2}\,d\upsilon\\ &= \frac{1}{9}\frac{\upsilon^{3/2}}{3/2} + c \quad \text{[by Eq. (3-51)]}\\ &= \frac{2}{27}(3x^3+10)^{3/2} + c\end{aligned}$$

***Trigonometric Substitution*** This technique is particularly well adapted to integrands in the form of radicals. For these the function is transformed to a trigonometric form. In the latter form they may be more easily recognizable relative to the identity formulas. These functions and their transformations are as follows:

$\sqrt{x^2 - a^2}$ Let $x = a\sec\theta$

$\sqrt{x^2 + a^2}$ Let $x = a\tan\theta$

$\sqrt{a^2 - x^2}$ Let $x = a\sin\theta$

***Example*** Find $\int \frac{\sqrt{4 - 9x^2}}{x^2}\,dx$. Let $x = \frac{2}{3}\sin\theta$; then $dx = \frac{2}{3}\cos\theta\,d\theta$.

$$\begin{aligned}3\int \frac{\sqrt{(2/3)^2 - x^2}}{x^2}\,dx &= 3\int \frac{2/3\sqrt{1-\sin^2\theta}}{(2/3)^2\sin^2\theta}\left(\frac{2}{3}\cos\theta\,d\theta\right)\\ &= 3\int \frac{\cos^2\theta}{\sin^2\theta}\,d\theta = 3\int \cot^2\theta\,d\theta\\ &= -3\cot\theta - 3\theta + c \text{ by trigonometric transform}\\ &= -\frac{\sqrt{4-9x^2}}{x} - 3\sin^{-1}\frac{3}{2}x + c \text{ in terms of } x\end{aligned}$$

***Algebraic Substitution*** Functions containing elements of the type $(a + bx)^{1/n}$ are best handled by the algebraic transformation $y^n = a + bx$.

***Example*** Find $\int \frac{x\,dx}{(3+4x)^{1/4}}$. Let $3 + 4x = y^4$; then $4\,dx = 4y^3\,dy$ and

$$\begin{aligned}\int \frac{x\,dx}{(3+4x)^{1/4}} &= \int \frac{\frac{y^4-3}{4}y^3\,dy}{y} = \frac{1}{4}\int y^2(y^4-3)\,dy\\ &= \frac{1}{4}\frac{y^7}{7} - \frac{3}{4}\frac{y^3}{3} + c = \frac{1}{28}(3+4x)^{7/4} - \frac{1}{4}(3+4x)^{3/4} + c\end{aligned}$$

***Partial Fractions*** Rational functions are of the type $f(x)/g(x)$ where $f(x)$ and $g(x)$ are polynomial expressions of degrees $m$ and $n$, respectively. If the degree of $f$ is higher than the degree of $g$, perform the algebraic division—the remainder will then be at least one degree less than the denominator. Consider the following types:

***Example*** Reducible denominator to linear unequal factors.

$$\begin{aligned}\frac{1}{x^3 - x^2 - 4x + 4} &= \frac{1}{(x+2)(x-2)(x-1)}\\ &= \frac{A}{x+2} + \frac{B}{x-2} + \frac{C}{x-1}\\ &= \frac{A(x-2)(x-1) + B(x+2)(x-1) + C(x+2)(x-2)}{(x+2)(x-2)(x-1)}\\ &= \frac{x^2(A+B+C) + x(-3A+B) + (2A-2B-4C)}{(x+2)(x-2)(x-1)}\end{aligned}$$

Equate coefficients and solve for $A$, $B$, and $C$.

$$A + B + C = 0 \qquad -3A + B = 0 \qquad 2A - 2B - 4C = 1$$

$$A = 1/12 \qquad B = 1/4 \qquad C = -1/3$$

$$\frac{1}{x^2 - x^2 - 4x + 4} = \frac{1}{12(x+2)} + \frac{1}{4(x-2)} - \frac{1}{3(x-1)}$$

Hence

$$\int \frac{dx}{x^3 - x^2 - 4x + 4} = \int \frac{dx}{12(x+2)} + \int \frac{dx}{4(x-2)} - \int \frac{dx}{3(x-1)}$$

***Integration by Parts*** An extremely useful formula for integration is the relation $d(u\upsilon) = u\,d\upsilon + \upsilon\,du$

and $$u\upsilon = \int u\,d\upsilon + \int \upsilon\,du$$

or $$\int u\,d\upsilon = u\upsilon - \int \upsilon\,du$$

It is particularly useful for trigonometric and exponential functions.

***Example*** Find $\int xe^x\,dx$. Let

$$u = x \quad \text{and} \quad dv = e^x\,dx$$
$$du = dx \qquad \upsilon = e^x$$

Therefore $\int xe^x\,dx = xe^x - \int e^x\,dx = xe^x - e^x + c$

***Example*** Find $\int e^x \sin x\,dx$. Let

$$u = e^x \qquad d\upsilon = \sin x\,dx$$
$$du = e^x\,dx \qquad \upsilon = -\cos x$$
$$\int e^x \sin x\,dx = -e^x \cos x + \int e^x \cos x\,dx$$

Again

$$u = e^x \qquad d\upsilon = \cos x\,dx$$
$$du = e^x\,dx \qquad \upsilon = \sin x$$
$$\int e^x \sin x\,dx = -e^x \cos x + e^x \sin x - \int e^x \sin x\,dx + c$$
$$= (e^x/2)(\sin x - \cos x) + \frac{c}{2}$$

***Series Expansion*** When an explicit function cannot be found, the integration can sometimes be carried out by a series expansion.

***Example*** Find $\int e^{-x^2}\,dx$. Since

$$e^{-x^2} = 1 - x^2 + \frac{x^4}{2!} - \frac{x^6}{3!} + \cdots$$
$$\int e^{-x^2}\,dx = \int dx - \int x^2\,dx + \int \frac{x^4}{2!}\,dx - \int \frac{x^6}{3!}\,dx + \cdots$$
$$= x - \frac{x^3}{3} + \frac{x^5}{5(2!)} - \frac{x^7}{7(3!)} + \cdots \quad \text{for all } x$$

**Definite Integral** The value of a definite integral depends on the limits $a$ and $b$ and any selected variable coefficients in the function but not on the dummy variable of integration $x$. Symbolically

$$F(x) = \int f(x)\,dx \qquad \text{indefinite integral where } dF/dx = f(x)$$
$$F(a,b) = \int_a^b f(x)\,dx \qquad \text{definite integral}$$
$$F(\alpha) = \int_a^b f(x,\alpha)\,dx F$$

There are certain restrictions of the integration definition: The function $f(x)$ must be continuous in the finite interval $(a, b)$ with at most a finite number of finite discontinuities. Relaxing two of these restrictions gives rise to so-called *improper integrals* and requires special handling. These occur when

1. The limits of integration are not both finite, i.e., $\int_0^\infty e^{-x}\,dx$.
2. The function becomes infinite within the interval of integration, i.e.,

$$\int_0^1 \frac{1}{\sqrt{x}}\,dx$$

Techniques for determining when integration is valid under these conditions are available in the references.

**Properties** The fundamental theorem of calculus states

$$\int_a^b f(x)\,dx = F(b) - F(a)$$

where $dF(x)/dx = f(x)$

Other properties of the definite integral are as follows:

$$\int_a^b c[f(x)\,dx] = c\int_a^b f(x)\,dx$$
$$\int_a^b [f_1(x) + f_2(x)]\,dx = \int_a^b f_1(x)\,dx + \int_a^b f_2(x)\,dx$$
$$\int_a^b f(x)\,dx = -\int_b^a f(x)\,dx$$
$$\int_a^b f(x)\,dx = \int_a^c f(x)\,dx + \int_c^b f(x)\,dx$$
$$\int_a^b f(x)\,dx = (b-a)f(\xi) \qquad \text{for some } \xi \text{ in } (a,b)$$

$$\frac{\partial}{\partial b}\int_a^b f(x)\,dx = f(b)$$
$$\frac{\partial}{\partial b}\int_a^b f(x)\,dx = -f(a)$$

$$\frac{dF(\alpha)}{d\alpha} = \int_a^b \frac{\partial f(x,\alpha)}{\partial \alpha}\,dx \qquad \text{if} \quad a \text{ and } b \text{ are constant}$$
$$\int_a^b dx \int_c^d f(x,\alpha)\,d\alpha = \int_c^d d\alpha \int_a^b f(x,\alpha)\,dx \tag{3-57}$$

When $F(x) = \int_{a(x)}^{b(x)} f(x,y)\,dy$ the Leibniz rule gives

$$\frac{dF}{dx} = \frac{db}{dx} f[x,b(x)] - \frac{da}{dx} f[x,a(x)] + \int_{a(x)}^{b(x)} \frac{\partial f}{\partial x}\,dy$$

***Example*** Find $\int_0^2 \frac{dx}{(x-1)^2}$. Direct application of the formula would yield the incorrect value

$$\int_0^2 \frac{dx}{(x-1)^2} = \left[-\frac{1}{x-1}\right]_0^2 = -2$$

Note that $f(x) = 1/(x-1)^2$ becomes unbounded as $x \to 1$ and by rule 2 the integral diverges and hence is said not to exist.

**Methods of Integration** All the methods of integration available for the indefinite integral can be used for definite integrals. In addition, several others are available for the latter integrals and are indicated below.

***Change of Variable*** This substitution is basically the same as previously indicated for indefinite integrals. However, for definite integrals, the limits of integration must also be changed: i.e., for $x = \phi(t)$,

$$\int_a^b f(x)\,dx = \int_{t_0}^{t_1} f[\phi(t)]\,\varphi'(t)\,dt$$

where $t = t_0$ when $x = a$
$t = t_1$ when $x = b$

***Example*** Find $\int_0^4 \sqrt{16 - x^2}\,dx$. Let

$$x = 4\sin\theta \qquad (x = 0, \theta = 0)$$
$$dx = 4\cos\theta\,d\theta \qquad (x = 4, \theta = \pi/2)$$

Then $\int_0^4 \sqrt{16 - x^2}\,dx = 16\int_0^{\pi/2} \cos^2\theta\,d\theta = 16[\frac{1}{2}\theta + \frac{1}{4}\sin 2\theta]_0^{\pi/2} = 4\pi$

**Integration** It is sometimes useful to generate a double integral to solve a problem. By this approach, the fundamental theorem indicated in Eq. (3-57) can be used.

***Example*** Find $\int_0^1 \frac{x^b - x^a}{\ln x}\,dx$.

Consider $\int_0^1 x^\alpha\,dx = \frac{1}{\alpha+1} \quad (\alpha > -1)$

Multiply both sides by $d\alpha$ and integrate between $a$ and $b$.

$$\int_a^b d\alpha \int_0^1 x^\alpha\,dx = \int_a^b \frac{d\alpha}{\alpha+1} = \ln\left|\frac{b+1}{a+1}\right|$$

But also

$$\int_a^b d\alpha \int_0^1 x^\alpha\,dx = \int_0^1 dx \int_a^b x^\alpha\,d\alpha = \int_0^1 \frac{x^b - x^a}{\ln x}\,dx$$

Therefore $\int_0^1 \frac{x^b - x^a}{\ln x}\,dx = \ln\left|\frac{b+1}{a+1}\right|$

# INFINITE SERIES

**References:** de Brujin, N. G., *Asymptotic Methods in Analysis*, Dover, New York, 2010; Zwillinger, D., *Table of Integrals, Series, and Products*, 8th ed., Academic, New York, 2014.

## DEFINITIONS

A succession of numbers or terms formed according to some definite rule is called a *sequence*. The indicated sum of the terms of a sequence is called a *series*. A series of the form $a_0 + a_1(x-c) + a_2(x-c)^2 + \cdots + a_n(x-c)^n + \cdots$ is called a *power series*.

Consider the sum of a finite number of terms in the geometric series (a special case of a power series).

$$S_n = a + ar + ar^2 + ar^3 + \cdots + ar^{n-1} \tag{3-58}$$

For any number of terms $n$, the sum equals

$$S_n = a\frac{1-r^n}{1-r}$$

In this form, the geometric series is assumed finite.

In the form of Eq. (3-58), it can further be defined that the terms in the series be nonending and therefore an infinite series.

$$S = a + ar + ar^2 + \cdots + ar^n + \cdots \tag{3-59}$$

However, the defined sum of the terms [Eq. (3-59)]

$$S_n = a\frac{1-r^n}{1-r} \qquad r \neq 1$$

while valid for any finite value of $r$ and $n$, now takes on a different interpretation. In this sense it is necessary to consider the limit of $S_n$ as $n$ increases indefinitely:

$$S = \lim_{n\to\infty} S_n$$
$$= a \lim_{n\to\infty} \frac{1-r^n}{1-r}$$

The infinite series converges if the limit of $S_n$ approaches a fixed finite value as $n$ approaches infinity. Otherwise, the series is *divergent*. If $r$ is less than 1 but greater than $-1$, the infinite series is convergent. For values outside of the range $-1 < r < 1$, the series is divergent because the sum is not defined. The range $-1 < r < 1$ is called the *region of convergence*. (We assume $a \neq 0$.)

There are also two types of convergent series. Consider the new series

$$S = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \cdots + (-1)^{n+1}\frac{1}{n} + \cdots \tag{3-60}$$

It can be shown that series (3-60) does converge to the value $S = \ln 2$. However, if each term is replaced by its absolute value, the series becomes unbounded and therefore divergent (unbounded divergent):

$$S = 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \cdots \tag{3-61}$$

In this case series (3-60) is defined as a conditionally convergent series. If the replacement series of absolute values also converges, the series is defined to converge absolutely. Series (3-60) is further defined as an alternating series, while series (3-61) is referred to as a positive series.

## OPERATIONS WITH INFINITE SERIES

1. The convergence or divergence of an infinite series is unaffected by the removal of a finite number of finite terms. This is a trivial theorem but useful to remember, especially when using the comparison test to be described in the subsection "Tests for Convergence and Divergence."

2. A power series can be inverted, provided the first-degree term is not zero. Given

$$y = b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 + b_7x^7 + \cdots$$

then
$$x = B_1y + B_2y^2 + B_3y^3 + B_4y^4 + B_5y^5 + B_6y^6 + B_7y^7 + \cdots$$

where
$$B_1 = 1/b_1$$
$$B_2 = -b_2/b_1^3$$
$$B_3 = (1/b_1^5)(2b_2^2 - b_1b_3)$$
$$B_4 = (1/b_1^7)(5b_1b_2b_3 - b_1^2b_4 - 5b_2^3)$$

Additional coefficients are available in the references.

3. Two series may be added or subtracted term by term provided each is a convergent series. The joint sum is equal to the sum (or difference) of the individuals.

4. The sum of two divergent series can be convergent. Similarly, the sum of a convergent series and a divergent series must be divergent.

5. A power series may be integrated term by term to represent the integral of the function within an interval of the region of convergence. If $f(x) = a_0 + a_1x + a_2x^2 + \cdots$, then

$$\int_{x_1}^{x_2} f(x)\,dx = \int_{x_1}^{x_2} a_0\,dx + \int_{x_1}^{x_2} a_1x\,dx + \int_{x_1}^{x_2} a_2x^2\,dx + \cdots$$

6. A power series may be differentiated term by term and represents the function $df(x)/dx$ within the same region of convergence as $f(x)$.

## TESTS FOR CONVERGENCE AND DIVERGENCE

In general, the problem of determining whether a given series will converge can require a great deal of ingenuity and resourcefulness. It is necessary to apply one or more of the developed theorems in an attempt to ascertain the convergence or divergence of the series under study. The following defined tests are given in relative order of effectiveness. For examples, see references on advanced calculus.

1. *Comparison test.* A series will converge if the absolute value of each term (with or without a finite number of terms) is less than the corresponding term of a known convergent series. Similarly, a positive series is divergent if it is termwise larger than a known divergent series of positive terms.

2. *nth-Term test.* A series is divergent if the $n$th term of the series does not approach zero as $n$ becomes increasingly large.

3. *Ratio test.* If the absolute ratio of the $n+1$ term divided by the $n$th term as $n$ becomes unbounded approaches
   a. A number less than 1, the series is absolutely convergent.
   b. A number greater than 1, the series is divergent.
   c. A number equal to 1, the test is inconclusive.

***Example*** For the power series

$$a_0 + a_1(x-x_0) + a_2(x-x_0)^2 + \cdots$$

the absolute ratio gives

$$\varepsilon = \lim_{n\to\infty}\left|\frac{a_{n+1}}{a_n}\right|\left|x-x_0\right| = \frac{1}{R}\left|x-x_0\right|$$

where $R$ is the inverse of the limit. For convergence $\varepsilon < 1$; therefore the series converges for $|x-x_0| < R$.

4. *Alternating-series Leibniz test.* If the terms of a series are alternately positive and negative and never increase in value, the absolute series will converge, provided that the terms tend to zero as a limit.

5. *Cauchy's root test.* If the $n$th root of the absolute value of the $n$th term, as $n$ becomes unbounded, approaches
   a. A number less than 1, the series is absolutely convergent.
   b. A number greater than 1, the series is divergent.
   c. A number equal to 1, the test is inconclusive.

6. *Maclaurin's integral test.* Suppose $\sum a_n$ is a series of positive terms and $f$ is a continuous decreasing function such that $f(x) \geq 0$ for $1 \leq x < \infty$ and $f(n) = a_n$. Then the series and the improper integral $\int_1^\infty f(x)\,dx$ either both converge or both diverge.

## SERIES SUMMATION AND IDENTITIES

**Sums for the First *n* Numbers to Integer Powers**

$$\sum_{j=1}^{n} j = \frac{n(n+1)}{2} = 1 + 2 + 3 + 4 + \cdots + n$$

$$\sum_{j=1}^{n} j^2 = \frac{n(n+1)(2n+1)}{6} = 1^2 + 2^2 + 3^2 + 4^2 + \cdots + n^2$$

$$\sum_{j=1}^{n} j^3 = \frac{n^2(n+1)^2}{4} = 1^3 + 2^3 + 3^3 + \cdots + n^3$$

**Arithmetic Progression**

$$\sum_{k=1}^{n}[a+(k-1)d]=a+(a+d)+(a+2d)+(a+3d)+\cdots+[a+(n-1)]d$$
$$=na+\frac{1}{2}n(n-1)d$$

**Geometric Progression**

$$\sum_{j=1}^{n}ar^{j-1}=a+ar+ar^2+ar^3+\cdots+ar^{n-1}=a\frac{1-r^n}{1-r}\qquad r\neq 1$$

**Harmonic Progression**

$$\sum_{k=0}^{n}\frac{1}{a+kd}=\frac{1}{a}+\frac{1}{a+d}+\frac{1}{a+2d}+\frac{1}{a+3d}+\frac{1}{a+4d}+\cdots+\frac{1}{a+nd}$$

The reciprocals of the terms of the arithmetic progression series are called a *harmonic progression*. No general summation formulas are available for this series.

**Binomial Series (See Also Elementary Algebra)**

$$(1\pm x)^n=1\pm nx+\frac{n(n-1)}{2!}x^2\pm\frac{n(n-1)(n-2)}{3!}x^3+\cdots\qquad (x^2<1)$$

**Taylor's Series**

$$f(h+x)=f(h)+xf'(h)+\frac{x^2}{2!}f''(h)+\frac{x^3}{3!}f'''(h)+\cdots$$

or $$f(x)=f(x_0)+f'(x_0)(x-x_0)+\frac{f'''(x_0)}{2!}(x-x_0)^2\frac{f'''(x_0)}{3!}(x-x_0)^3+\cdots$$

***Example*** Find a series expansion for $f(x)=\ln(1+x)$ about $x_0=0$.

$$f'(x)=(1+x)^{-1},\ f''(x)=-(1+x)^{-2},\ f'''(x)=2(1+x)^{-3},\text{ etc.}$$

Thus $$f(0)=0,\ f'(0)=1,\ f''(0)=-1,\ f'''(1)=2,\text{ etc.}$$

$$\ln(x+1)=x-\frac{x^2}{2}+\frac{x^3}{3}-\frac{x^4}{4}+\cdots+(-1)^{n+1}\frac{x^n}{n}+\cdots$$

which converges for $-1<x\leq 1$.

**Maclaurin's Series**

$$f(x)=f(0)+xf'(0)+\frac{x^2}{2!}f''(0)+\frac{x^3}{3!}f'''(0)+\cdots$$

This is simply a special case of Taylor's series when $h$ is set to zero.

**Exponential Series**

$$e^x=1+x+\frac{x^2}{2!}+\frac{x^3}{3!}+\cdots+\frac{x^n}{n!}+\cdots\qquad -\infty<x<\infty$$

**Logarithmic Series**

$$\ln x=\frac{x-1}{x}+\frac{1}{2}\left(\frac{x-1}{x}\right)^2+\frac{1}{3}\left(\frac{x-1}{x}\right)^3+\cdots\quad (x>\tfrac{1}{2})$$
$$\ln x=2\left[\left(\frac{x-1}{x+1}\right)+\frac{1}{3}\left(\frac{x-1}{x+1}\right)^3\right]+\cdots\quad (x>0)$$

**Trigonometric Series***

$$\sin x=x-\frac{x^3}{3!}+\frac{x^5}{5!}-\frac{x^7}{7!}+\cdots\qquad -\infty<x<\infty$$
$$\cos x=1-\frac{x^2}{2!}+\frac{x^4}{4!}-\frac{x^6}{6!}+\cdots\qquad -\infty<x<\infty$$
$$\sin^{-1}x=x+\frac{x^3}{6}+\frac{1}{2}\cdot\frac{3}{4}\cdot\frac{x^5}{5}+\frac{1}{2}\cdot\frac{3}{4}\cdot\frac{5}{6}\cdot\frac{x^7}{7}+\cdots\qquad (x^2<1)$$
$$\tan^{-1}x=x-\frac{1}{3}x^3+\frac{1}{5}x^5-\frac{1}{7}x^7+\cdots\qquad (x^2<1)$$

**Taylor Series** The Taylor series for a function of two variables, expanded about the point $(x_0, y_0)$, is

$$f(x,y)=f(x_0,y_0)+\left.\frac{\partial f}{\partial x}\right|_{x_0,y_0}(x-x_0)+\left.\frac{\partial f}{\partial y}\right|_{x_0,y_0}(y-y_0)$$
$$+\frac{1}{2!}\left[\left.\frac{\partial^2 f}{\partial x^2}\right|_{x_0,y_0}(x-x_0)^2+2\left.\frac{\partial^2 f}{\partial x\,\partial y}\right|_{x_0,y_0}(x-x_0)(y-y_0)+\left.\frac{\partial^2 f}{\partial y^2}\right|_{x_0,y_0}(y-y_0)^2\right]+\cdots$$

**Partial Sums of Infinite Series, and How They Grow** Calculus textbooks devote much space to tests for convergence and divergence of series that are of little practical value, since a convergent series either converges rapidly, in which case almost any test (among those presented in the preceding subsections) will do, or it converges slowly, in which case it is not going to be of much use unless there is some way to get at its sum without adding an unreasonable number of terms. To find out, as accurately as possible, how fast a convergent series converges and how fast a divergent series diverges, see Boas, R. P., Jr., *Am. Math. Mon.* **84:** 237–258 (1977).

*The tan $x$ series has awkward coefficients and should be computed as $\left[(\text{sign})\frac{\sin x}{\sqrt{1-\sin^2 x}}\right]$

# COMPLEX VARIABLES

**REFERENCES:** Ablowitz, M. J., and A. S. Fokas, *Complex Variables: Introduction and Applications*, 2d ed., Cambridge University Press, New York, 2012; Asmar, N., and G. C. Jones, *Applied Complex Analysis with Partial Differential Equations*, Prentice-Hall, Upper Saddle River, N.J., 2002; Brown, J. W., and R. V. Churchill, *Complex Variables and Applications*, 9th ed., McGraw-Hill, New York, 2013; Kwok, Y. K., *Applied Complex Variables for Scientists and Engineers*, 2d ed., Cambridge University Press, New York, 2010.

Numbers of the form $z=x+iy$, where $x$ and $y$ are real, $i^2=-1$, are called *complex numbers*. The numbers $z=x+iy$ are representable in the plane, as shown in Fig. 3-42. The following definitions and terminology are used:

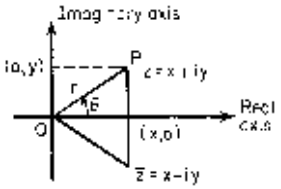

**FIG. 3-42** Complex plane.

1. Distance $OP=r=$ modulus of $z$ written $|z|$. $|z|=\sqrt{x^2+y^2}$
2. $x$ is the real part of $z$.
3. $y$ is the imaginary part of $z$.
4. The angle $\theta$, $0\leq\theta<2\pi$, measured counterclockwise from the positive $x$ axis to $OP$, is the argument of $z$. $\theta=\arctan y/x=\arcsin y/r=\arccos x/r$ if $x\neq 0$, $\theta=\pi/2$ if $x=0$ and $y>0$.
5. The numbers $r$, $\theta$ are the polar coordinates of $z$.
6. $\bar{z}=x-iy$ is the complex conjugate of $z$.

## ALGEBRA

Let $z_1=x_1+iy_1$ and $z_2=x_2+iy_2$.

**Equality** $z_1=z_2$ if and only if $x_1=x_2$ and $y_1=y_2$.
**Addition** $z_1+z_2=(x_1+x_2)+i(y_1+y_2)$.
**Subtraction** $z_1-z_2=(x_1-x_2)+i(y_1-y_2)$.
**Multiplication** $z_1z_2=(x_1x_2-y_1y_2)+i(x_1y_2+x_2y_1)$.

**Division** $$z_1/z_2=\frac{x_1x_2+y_1y_2}{x_2^2+y_2^2}+i\frac{x_2y_1-x_1y_2}{x_2^2+y_2^2},\ z_2\neq 0.$$

## SPECIAL OPERATIONS

$z\bar{z} = x^2 + y^2 = |z|^2$; $\overline{z_1 \pm z_2} = \bar{z}_1 \pm \bar{z}_2$; $\bar{\bar{z}}_1 = z_1$; $\overline{z_1 z_2} = \bar{z}_1\,\bar{z}_2$; $|z_1 \cdot z_2| = |z_1| \cdot |z_2|$; arg $(z_1 \cdot z_2)$ = arg $z_1$ + arg $z_2$; arg $(z_1/z_2)$ = arg $z_1$ − arg $z_2$; $i^{4n} = 1$ for $n$ any integer; $i^{2n} = -1$ where $n$ is any odd integer; $z + \bar{z} = 2x$; $z - \bar{z} = 2iy$.

Every complex quantity can be expressed in the form $x + iy$.

## TRIGONOMETRIC REPRESENTATION

By referring to Fig. 3-42, there results $x = r \cos \theta$ and $y = r \sin \theta$ so that $z = x + iy = r(\cos \theta + i \sin \theta)$, which is called the *polar form* of the complex number. $\cos \theta + i \sin \theta = e^{i\theta}$. Hence $z = x + iy = re^{i\theta}$. $\bar{z} = x - iy = re^{-i\theta}$. Two important results from this are $\cos \theta = (e^{i\theta} + e^{-i\theta})/2$ and $\sin \theta = (e^{i\theta} - e^{-i\theta})/2i$. Let $z_1 = r_1 e^{i\theta_1}$ and $z_2 = r_2 e^{i\theta_2}$. This form is convenient for multiplication for $z_1 z_2 = r_1 r_2 e^{i(\theta_1 + \theta_2)}$ and for division for $z_1/z_2 = (r_1/r_2)e^{i(\theta_1 - \theta_2)}$, $z_2 \neq 0$.

## POWERS AND ROOTS

If $n$ is a positive integer, $z^n = (re^{i\theta})^n = r^n e^{in\theta} = r^n(\cos n\theta + i \sin n\theta)$.

If $n$ is a positive integer,

$$z^{1/n} = r^{1/n} e^{i[(\theta + 2k\pi)/n]} = r^{1/n}\left[\cos\left(\frac{\theta + 2k\pi}{n}\right) + i \sin\left(\frac{\theta + 2k\pi}{n}\right)\right]$$

and selecting values of $k = 0, 1, 2, 3, \ldots, n-1$ gives the $n$ distinct values of $z^{1/n}$. The $n$ roots of a complex quantity are uniformly spaced around a circle with radius $r^{1/n}$ in the complex plane in a symmetric fashion.

***Example*** Find the three cube roots of −8. Here $r = 8$, $\theta = \pi$. The roots are $z_0 = 2(\cos \pi/3 + i \sin \pi/3) = 1 + i\sqrt{3}$, $z_1 = 2(\cos \pi + i \sin \pi) = -2$, and $z_2 = 2(\cos 5\pi/3 + i \sin 5\pi/3) = 1 - i\sqrt{3}$.

## ELEMENTARY COMPLEX FUNCTIONS

**Polynomials** A polynomial in $z$, $a_n z^n + a_{n-1} z^{n-1} + \cdots + a_0$, where $n$ is a positive integer, is simply a sum of complex numbers times integral powers of $z$ which have already been defined. Every polynomial of degree $n$ has precisely $n$ complex roots provided each multiple root of multiplicity $m$ is counted $m$ times.

**Exponential Functions** The exponential function $e^z$ is defined by the equation $e^z = e^{x+iy} = e^x \cdot e^{iy} = e^x(\cos y + i \sin y)$. Properties: $e^0 = 1$; $e^{z_1} e^{z_2} = e^{z_1 + z_2}$; $e^{z_1/z_2} = e^{z_1 - z_2}$; $e^{z + 2k\pi i} = e^z$, $k$ an integer.

**Trigonometric Functions** $\sin z = (e^{iz} - e^{-iz})/2i$; $\cos z = (e^{iz} + e^{-iz})/2$; $\tan z = \sin z/\cos z$; $\cot z = \cos z/\sin z$; $\sec z = 1/\cos z$; $\csc z = 1/\sin z$. Fundamental identities for these functions are the same as their real counterparts. Thus $\cos^2 z + \sin^2 z = 1$, $\cos(z_1 \pm z_2) = \cos z_1 \cos z_2 \mp \sin z_1 \sin z_2$, $\sin(z_1 \pm z_2) = \sin z_1 \cos z_2 \pm \cos z_1 \sin z_2$. The sine and cosine of $z$ are periodic functions of period $2\pi$; thus $\sin(z + 2\pi) = \sin z$. For computation purposes $\sin z = \sin(x + iy) = \sin x \cosh y + i \cos x \sinh y$, where $\sin x$, $\cosh y$, etc., are the real trigonometric and hyperbolic functions. Similarly, $\cos z = \cos x \cosh y - i \sin x \sinh y$. If $x = 0$ in the results given, $\cos iy = \cosh y$ and $\sin iy = i \sinh y$.

***Example*** Find all solutions of $\sin z = 3$. From previous data $\sin z = \sin x \cosh y + i \cos x \sinh y = 3$. Equating real and imaginary parts gives $\sin x \cosh y = 3$ and $\cos x \sinh y = 0$. The second equation can hold for $y = 0$ or for $x = \pi/2, 3\pi/2, \ldots$. If $y = 0$, $\cosh 0 = 1$ and $\sin x = 3$ is impossible for real $x$. Therefore, $x = \pm\pi/2, \pm 3\pi/2, \ldots, \pm(2n+1)\pi/2$, $n = 0, \pm 1, \pm 2, \ldots$. However, $\sin 3\pi/2 = -1$ and $\cosh y \geq 1$. Hence $x = \pi/2, 5\pi/2, \ldots$. The solution is $z = [(4n+1)\pi]/2 + i \cosh^{-1} 3$, $n = 0, 1, 2, 3, \ldots$.

***Example*** Find all solutions of $e^z = -i$. $e^z = e^x(\cos y + i \sin y) = -i$. Equating real and imaginary parts gives $e^x \cos y = 0$, $e^x \sin y = -1$ from the first $y = \pm\pi/2, \pm 3\pi/2, \ldots$. But $e^x > 0$. Therefore, $y = 3\pi/2, 7\pi/2, -\pi/2, \ldots$. Then $x = 0$. The solution is $z = i[(4n+3)\pi]/2$.

Two important facets of these functions should be recognized. First, $\sin z$ is *unbounded*; second, $e^z$ takes *all* complex values *except* 0.

**Hyperbolic Functions** $\sinh z = (e^z - e^{-z})/2$; $\cosh z = (e^z + e^{-z})/2$; $\tanh z = \sinh z/\cosh z$; $\coth z = \cosh z/\sinh z$; $\operatorname{csch} z = 1/\sinh z$; $\operatorname{sech} z = 1/\cosh z$. Identities are $\cosh^2 z - \sinh^2 z = 1$; $\sinh(z_1 + z_2) = \sinh z_1 \cosh z_2 + \cosh z_1 \sinh z_2$; $\cosh(z_1 + z_2) = \cosh z_1 \cosh z_2 + \sinh z_1 \sinh z_2$; $\cosh z + \sinh z = e^z$; $\cosh z - \sinh z = e^{-z}$. The hyperbolic sine and hyperbolic cosine are periodic functions with the imaginary period $2\pi i$. That is, $\sinh(z + 2\pi i) = \sinh z$.

**Logarithms** The logarithm of $z$, $\log z = \log|z| + i(\theta + 2n\pi)$, where $\log|z|$ is taken to the base $e$ and $\theta$ is the principal argument of $z$, that is, the particular argument lying in the interval $0 \leq \theta < 2\pi$. The logarithm of $z$ is infinitely many valued. If $n = 0$, the resulting logarithm is called the *principal value*. The familiar laws $\log z_1 z_2 = \log z_1 + \log z_2$, $\log z_1/z_2 = \log z_1 - \log z_2$, and $\log z^n = n \log z$ hold for the principal value.

General powers of $z$ are defined by $z^\alpha = e^{\alpha \log z}$. Since $\log z$ is infinitely many valued, so too is $z^\alpha$ unless $\alpha$ is a rational number.

DeMoivre's formula can be derived from properties of $e^z$.

$$z^n = r^n(\cos\theta + i \sin\theta)^n = r^n(\cos n\theta + i \sin n\theta)$$

Thus $$(\cos\theta + i \sin\theta)^n = \cos n\theta + i \sin n\theta$$

## COMPLEX FUNCTIONS (ANALYTIC)

In the real-number system $a$ greater than $b$ ($a > b$) and $b$ less than $c$ ($b < c$) define an order relation. These relations have no meaning for complex numbers. The absolute value is used for ordering. Some important relations follow: $|z| \geq x$; $|z| \geq y$; $|z_1 \pm z_2| \leq |z_1| + |z_2|$; $|z_1 - z_2| \geq ||z_1| - |z_2||$; $|z| \geq (|x| + |y|)/\sqrt{2}$. Parts of the complex plane, commonly called *regions* or *domains*, are described by using inequalities.

***Example*** $|z - 3| \leq 5$. This is equivalent to $\sqrt{(x-3)^2 + y^2} \leq 5$, which is the set of all points within and on the circle, centered at $x = 3$, $y = 0$ of radius 5.

***Example*** $|z - 1| \leq x$ represents the set of all points inside and on the parabola $2x = y^2 + 1$ or, equivalently, $2x \geq y^2 + 1$.

**Functions of a Complex Variable** If $z = x + iy$, $w = u + i\upsilon$ and if for each value of $z$ in some region of the complex plane one or more values of $w$ are defined, then $w$ is said to be a function of $z$, $w = f(z)$. Some of these functions have already been discussed, such as $\sin z$ and $\log z$. All functions are reducible to the form $w = u(x, y) + i\upsilon(x, y)$, where $u$ and $\upsilon$ are real functions of the real variables $x$ and $y$.

***Example*** $z^3 = (x + iy)^3 = x^3 + 3x^2(iy) + 3x(iy)^2 + (iy)^3 = (x^3 - 3xy^2) + i(3x^2 y - y^3)$.

**Differentiation** The *derivative* of $w = f(z)$ is

$$\frac{dw}{dz} = \lim_{\Delta z \to 0} \frac{f(z + \Delta z) - f(z)}{\Delta z}$$

and for the derivative to exist, the limit must be the same no matter how $\Delta z$ approaches zero. If $w_1$ and $w_2$ are differentiable functions of $z$, the following rules apply:

$$\frac{d(w_1 \pm w_2)}{dz} = \frac{dw_1}{dz} \pm \frac{dw_2}{dz} \qquad \frac{d(w_1 w_2)}{dz} = w_2 \frac{dw_1}{dz} + w_1 \frac{dw_2}{dz}$$

$$\frac{d(w_1/w_2)}{dz} = \frac{w_2(dw_1/dz) - w_1(dw_2/dz)}{w_2^2}$$

and $$\frac{dw_1^n}{dz} = n w_1^{n-1} \frac{dw_1}{dz}$$

For $w = f(z)$ to be differentiable, it is necessary that $\partial u/\partial x = \partial\upsilon/\partial y$ and $\partial\upsilon/\partial x = -\partial u/\partial y$. The last two equations are called the *Cauchy-Riemann equations*. The derivative

$$\frac{dw}{dz} = \frac{\partial u}{\partial x} + i\frac{\partial v}{\partial x} = \frac{\partial \upsilon}{\partial y} - i\frac{\partial u}{\partial y}$$

If $f(z)$ possesses a derivative at $z_0$ and at every point in some neighborhood of $z_0$, then $f(z)$ is said to be *analytic* or *homomorphic* at $z_0$. If the Cauchy-Riemann equations are satisfied and

$$u, \upsilon, \frac{\partial u}{\partial x}, \frac{\partial u}{\partial y}, \frac{\partial \upsilon}{\partial x}, \frac{\partial \upsilon}{\partial y}$$

are continuous in a region of the complex plane, then $f(z)$ is analytic in that region.

***Example*** $w = z\bar{z} = x^2 + y^2$. Here $u = x^2 + y^2$, $\upsilon = 0$. $\partial u/\partial x = 2x$, $\partial u/\partial y = 2y$, $\partial\upsilon/\partial x = \partial\upsilon/\partial y = 0$. These are continuous everywhere, but the Cauchy-Riemann equations hold only at the origin. Therefore, $w$ is nowhere analytic, but it is differentiable at $z = 0$ only.

***Example*** $w = e^z = e^x \cos y + ie^x \sin y$. $u = e^x \cos y$ and $\upsilon = e^x \sin y$. $\partial u/\partial x = e^x \cos y$, $\partial u/\partial y = -e^x \sin y$, $\partial\upsilon/\partial x = e^x \sin y$, $\partial\upsilon/\partial y = e^x \cos y$. The continuity and Cauchy-Riemann requirements are satisfied for all finite $z$. Hence $e^z$ is analytic (except at $\infty$) and $dw/dz = \partial u/\partial x + i(\partial\upsilon/\partial x) = e^z$.

***Example*** $w = \frac{1}{z} = \frac{x - iy}{x^2 + y^2} = \frac{x}{x^2 + y^2} - i\frac{y}{x^2 + y^2}$

It is easy to see that $dw/dz$ exists except at $z = 0$. Thus $1/z$ is analytic except at $z = 0$.

**Singular Points** If $f(z)$ is analytic in a region except at certain points, those points are called *singular points*.

***Example*** $1/z$ has a singular point at zero.

***Example*** $\tan z$ has singular points at $z = \pm(2n+1)(\pi/2)$, $n = 0, 1, 2, \ldots$. The derivatives of the common functions, given earlier, are the same as their real counterparts.

***Example*** $(d/dz)(\ln z) = 1/z$, $(d/dz)(\sin z) = \cos z$.

**Harmonic Functions** Both the *real* and the *imaginary* parts of any analytic function $f = u + i\upsilon$ satisfy Laplace's equation $\partial^2\phi/\partial x^2 + \partial^2\phi/\partial y^2 = 0$. A function which possesses continuous second partial derivatives and satisfies Laplace's equation is called a *harmonic function.*

***Example*** $e^z = e^x \cos y + ie^x \sin y$. $u = e^x \cos y$, $\partial u/\partial x = e^x \cos y$, $\partial^2 u/\partial x^2 = e^x \cos y$, $\partial u/\partial y = -e^x \sin y$, $\partial^2 u/\partial y^2 = -e^x \cos y$. Clearly $\partial^2 u/\partial x^2 + \partial^2 u/\partial y^2 = 0$. Similarly, $\upsilon = e^x \sin y$ is also harmonic.

If $w = u + i\upsilon$ is analytic, the curves $u(x, y) = c$ and $\upsilon(x, y) = k$ intersect at right angles, if $w'(z) \neq 0$.

**Integration** In much of the work with complex variables a simple extension of integration called *line* or *curvilinear integration* is of fundamental importance. Since any complex line integral can be expressed in terms of real line integrals, we define only real line integrals. Let $F(x, y)$ be a real, continuous function of $x$ and $y$, and let $c$ be any continuous curve of finite length joining points $A$ and $B$ (Fig. 3-43). $F(x, y)$ is not related to the curve $c$. Divide $c$ into $n$ segments, $\Delta s_i$, whose projection on the $x$ axis is $\Delta x_i$ and on the $y$ axis is $\Delta y_i$. Let $(\varepsilon_i, \eta_i)$ be the coordinates of an arbitrary point on $\Delta s_i$. The limits of the sums

$$\lim_{\Delta s_i \to 0} \sum_{i=1}^{n} F(\varepsilon_i, \eta_i)\,\Delta s_i = \int_c F(x, y)\,ds$$

$$\lim_{\Delta s_i \to 0} \sum_{i=1}^{n} F(\varepsilon_i, \eta_i)\,\Delta x_i = \int_c F(x, y)\,dx$$

$$\lim_{\Delta s_i \to 0} \sum_{i=1}^{n} F(\varepsilon_i, \eta_i)\,\Delta y_i = \int_c F(x, y)\,dy$$

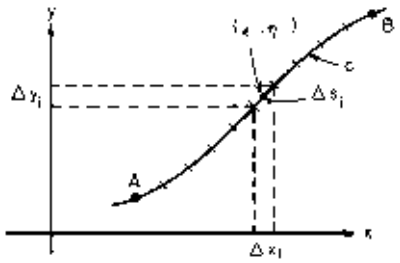

**FIG. 3-43** Line integral.

are known as *line integrals*. Much of the initial strangeness of these integrals will vanish if it is observed that the ordinary definite integral $\int_a^b f(x)\,dx$ is just a line integral in which the curve $c$ is a line segment on the $x$ axis and $F(x, y)$ is a function of $x$ alone. The evaluation of line integrals can be reduced to evaluation of ordinary integrals.

***Example*** $\int_c y(1+x)\,dy$, where $c$: $y = 1 - x^2$ from $(-1, 0)$ to $(1, 0)$. Clearly $y = 1 - x^2$, $dy = -2x\,dx$. Thus $\int_c y(1+x)\,dy = -2\int_{-1}^{1}(1-x^2)(1+x)x\,dx = -{}^8\!/_{15}$.

Let $f(z)$ be any function of $z$, analytic or not, and $c$ any curve as above. The complex integral is calculated as $\int_c f(z)\,dz = \int_c (u\,dx - \upsilon\,dy) + i\int_c (\upsilon\,dx + u\,dy)$, where $f(z) = u(x, y) + i\upsilon(x, y)$. Properties of line integrals are the same as for ordinary integrals. That is, $\int_c [f(z) \pm g(z)]\,dz = \int_c f(z)\,dz \pm \int_c g(z)\,dz$; $\int_c kf(z)\,dz = k\int_c f(z)\,dz$ for any constant $k$, etc.

***Example*** $\int_c (x^2 + iy)\,dz$ along $c$: $y = x$, 0 to $1 + i$. This becomes

$$\int_c (x^2 + iy)\,dz = \int_c (x^2\,dx - y\,dy)$$

$$+ i\int_c (y\,dx + x^2\,dy) = \int_0^1 x^2\,dx - \int_0^1 x\,dx + i\int_0^1 x\,dx + i\int_0^1 x^2\,dx = -{}^1\!/_6 + 5i/6$$

**Conformal Mapping** Every function of a complex variable $w = f(z) = u(x, y) + i\upsilon(x, y)$ transforms the $x, y$ plane into the $u, \upsilon$ plane in some manner. A conformal transformation is one in which angles between curves are preserved in *magnitude* and *sense*. Every analytic function, except at those points where $f'(z) = 0$, is a conformal transformation. See Fig. 3-44.

***Example*** $w = z^2$. $u + i\upsilon = (x^2 - y^2) + 2ixy$ or $u = x^2 - y^2$, $\upsilon = 2xy$. These are the transformation equations between the $(x, y)$ and $(u, \upsilon)$ planes. Lines parallel to the $x$ axis, $y = c_1$ map into curves in the $u, \upsilon$ plane with parametric equations $u = x^2 - c_1^2$, $\upsilon = 2c_1x$. Eliminating $x$, $u = (\upsilon^2/4c_1^2) - c_1^2$, which represents a family of parabolas with the origin of the $w$ plane as focus, the line $\upsilon = 0$ as axis and opening to the right. Similar arguments apply to $x = c_2$.

The principles of complex variables are useful in the solution of a variety of applied problems, including Laplace transforms (see Integral Transforms) and process control (Sec. 8).

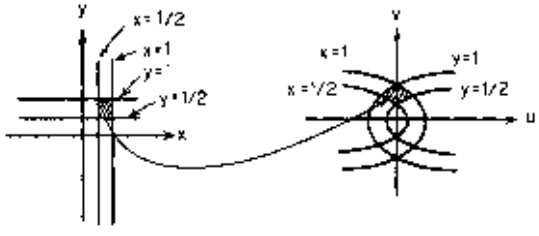

**FIG. 3-44** Conformal transformation.

# DIFFERENTIAL EQUATIONS

The natural laws in any scientific or technological field are not regarded as precise and definitive until they have been expressed in mathematical form. Such a form, often an equation, is a relation between the quantity of interest, say, product yield, and independent variables such as time and temperature upon which yield depends. When it happens that this equation involves, besides the function itself, one or more of its derivatives it is called a differential equation.

***Example*** The rate of the homogeneous bimolecular reaction $A + B \xrightarrow{k} C$ is characterized by the differential equation $dx/dt = k(a - x)(b - x)$, where $a$ = initial concentration of $A$, $b$ = initial concentration of $B$, and $x = x(t)$ = concentration of $C$ as a function of time $t$.

***Example*** The differential equation of heat conduction in a moving fluid with velocity components $\upsilon_x$, $\upsilon_y$ is

$$\frac{\partial T}{\partial t} + \upsilon_x \frac{\partial T}{\partial x} + \upsilon_y \frac{\partial T}{\partial y} = \frac{k}{\rho c_p}\left(\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2}\right)$$

where $T = T(x, y, t)$ = temperature, $k$ = thermal conductivity, $\rho$ = density, and $c_p$ = specific heat at constant pressure.

## ORDINARY DIFFERENTIAL EQUATIONS

When the function involved in the equation depends upon only one variable, its derivatives are ordinary derivatives and the differential equation is called an ordinary differential equation. When the function depends upon several independent variables, then the equation is called a partial differential equation. The theories of ordinary and partial differential equations are quite different. In almost every respect the latter is more difficult.

Whichever the type, a differential equation is said to be of $n$th order if it involves derivatives of order $n$ but no higher. The equation in the first example is of first order and that in the second example of second order. The degree of a differential equation is the power to which the derivative of the highest order is raised after the equation has been cleared of fractions and radicals in the dependent variable and its derivatives.

A relation between the variables, involving no derivatives, is called a solution of the differential equation if this relation, when substituted in the equation, satisfies the equation. A solution of an ordinary differential equation which includes the maximum possible number of "arbitrary" constants is called the *general solution.* The maximum number of "arbitrary" constants is exactly equal to the order of the differential equation. If any set of specific values of the constants is chosen, the result is called a *particular solution.*

***Example*** The general solution of $(d^2x/dt^2) + k^2x = 0$ is $x = A \cos kt + B \sin kt$, where $A$ and $B$ are arbitrary constants. A particular solution is $x = \frac{1}{2} \cos kt + 3 \sin kt$.

In the case of some equations still other solutions exist called singular solutions. A *singular solution* is any solution of the differential equation which is not included in the general solution.

***Example*** $y = x(dy/dx) - \frac{1}{4}(dy/dx)^2$ has the general solution $y = cx - \frac{1}{4}c^2$, where $c$ is an arbitrary constant; $y = x^2$ is a singular solution, as is easily verified.

## ORDINARY DIFFERENTIAL EQUATIONS OF THE FIRST ORDER

**Equations with Separable Variables** Every differential equation of the first order and of the first degree can be written in the form $M(x, y)\,dx + N(x, y)dy = 0$. If the equation can be transformed so that $M$ does not involve $y$ and $N$ does not involve $x$, then the variables are said to be separated. The solution can then be obtained by quadrature, which means that $y = \int f(x)dx + c$, which may or may not be expressible in simpler form.

***Exact Equations*** The equation $M(x, y)\,dx + N(x, y)\,dy = 0$ is exact if and only if $\partial M/\partial y = \partial N/\partial x$. In this case there exists a function $w = f(x, y)$ such that $\partial f/\partial x = M$, $\partial f/\partial y = N$, and $f(x, y) = C$ is the required solution. $f(x, y)$ is found as follows: treat $y$ as though it were constant and evaluate $\int M(x, y)\,dx$. Then treat $x$ as though it were constant and evaluate $\int N(x, y)\,dy$. The sum of all unlike terms in these two integrals (including no repetitions) is $f(x, y)$.

***Example*** $(2xy - \cos x)\,dx + (x^2 - 1)\,dy = 0$ is exact for $\partial M/\partial y = 2x$, $\partial N/\partial x = 2x$. $\int M\,dx = \int(2xy - \cos x)\,dx = x^2y - \sin x$, $\int N\,dy = \int(x^2 - 1)\,dy = x^2y - y$. The solution is $x^2y - \sin x - y = C$, as may easily be verified.

***Linear Equations*** A differential equation is said to be linear when it is of first degree in the dependent variable and its derivatives. The general linear first-order differential equation has the form $dy/dx + P(x)y = Q(x)$. Its general solution is

$$y = e^{-\int P\,dx}\left[\int Qe^{\int P\,dx}\,dx + C\right]$$

***Example*** A tank initially holds 200 gal of a salt solution in which 100 lb is dissolved. Six gallons of brine containing 4 lb of salt run into the tank per minute. If mixing is perfect and the output rate is 4 gal/min, what is the amount $A$ of salt in the tank at time $t$? The differential equation of $A$ is $dA/dt = 4 - 2A/[100 + t]$. Its general solution is $A = (4/3)(100 + t) + C/(100 + t)^2$. At $t = 0$, $A = 100$; so the particular solution is $A = (4/3)(100 + t) - (1/3) \times 10^6/(100 + t)^2$.

## ORDINARY DIFFERENTIAL EQUATIONS OF HIGHER ORDER

The higher-order differential equations, especially those of order 2, are of great importance because of physical situations describable by them.

***Equation $y^{(n)} = f(x)$.*** The superscript $(n)$ means $n$ derivatives. Such a differential equation can be solved by $n$ integrations. The solution will contain $n$ arbitrary constants.

**Linear Differential Equations with Constant Coefficients and Right-Hand Member of Zero (Homogeneous)** The solution of $y'' + ay' + by = 0$ depends upon the nature of the roots of the characteristic equation $m^2 + am + b = 0$ obtained by substituting the trial solution $y = e^{mx}$ in the equation.

***Distinct Real Roots*** If the roots of the characteristic equation are distinct real roots, $r_1$ and $r_2$, say, the solution is $y = Ae^{r_1x} + Be^{r_2x}$, where $A$ and $B$ are arbitrary constants.

***Example*** $y'' + 4y' + 3 = 0$. The characteristic equation is $m^2 + 4m + 3 = 0$. The roots are $-3$ and $-1$, and the general solution is $y = Ae^{-3x} + Be^{-x}$.

***Multiple Real Roots*** If $r_1 = r_2$, the solution of the differential equation is $y = e^{r_1x}(A + Bx)$.

***Example*** $y'' + 4y + 4 = 0$. The characteristic equation is $m^2 + 4m + 4 = 0$ with roots $-2$ and $-2$. The solution is $y = e^{-2x}(A + Bx)$.

***Complex Roots*** If the characteristic roots are $p \pm iq$, then the solution is $y = e^{px} \times (A \cos qx + B \sin qx)$.

***Example*** The differential equation $My'' + Ay' + ky = 0$ represents the vibration of a linear system of mass $M$, spring constant $k$, and damping constant $A$. If $A < 2\sqrt{kM}$, the roots of the characteristic equation

$$Mm^2 + Am + k = 0 \text{ are complex: } -\frac{A}{2M} \pm i\sqrt{\frac{k}{M} - \left(\frac{A}{2M}\right)^2}$$

and the solution is

$$y = e^{-(At/2M)}\left[c_1 \cos\left(\sqrt{\frac{k}{M} - \left(\frac{A}{2M}\right)^2}\right)t + ic_2 \sin\left(\sqrt{\frac{k}{M} - \left(\frac{A}{2M}\right)^2}\right)t\right]$$

This solution is oscillatory, representing undercritical damping.

All these results generalize to homogeneous linear differential equations with constant coefficients of order higher than 2. These equations (especially of order 2) have been much used because of the ease of solution. Oscillations, electric circuits, diffusion processes, and heat flow problems are a few examples for which such equations are useful.

***Second-Order Equations: Dependent Variable Missing*** Such an equation is of the form

$$F\left(x, \frac{dy}{dx}, \frac{d^2y}{dx^2}\right) = 0$$

It can be reduced to a first-order equation by substituting $p = dy/dx$ and $dp/dx = d^2y/dx^2$.

***Second-Order Equations: Independent Variable Missing*** Such an equation is of the form

$$F\left(y, \frac{dy}{dx}, \frac{d^2y}{dx^2}\right) = 0$$

Set $$\frac{du}{dx} = p,\ \frac{d^2y}{dx^2} = p\frac{dp}{dy}$$

The result is a first-order equation in $p$

$$F\left(y, p, p\frac{dp}{dy}\right) = 0$$

***Example*** The capillary curve for one vertical plate is given by

$$\frac{d^2y}{dx^2} = \frac{4y}{c^2}\left[1 + \left(\frac{dy}{dx}\right)^2\right]^{3/2}$$

Its solution by this technique is

$$x + \sqrt{c^2 - y^2} - \sqrt{c^2 - h_0^2} = \frac{c}{2}\left(\cosh^{-1}\frac{c}{y} - \cosh^{-1}\frac{c}{h_0}\right)$$

where $c$ and $h_0$ are physical constants.

***Example*** The equation governing chemical reaction in a porous catalyst in plane geometry of thickness $L$ is

$$D\frac{d^2c}{dx^2} = k\,f(c),\quad \frac{dc}{dx}(0) = 0,\quad c(L) = c_v$$

where $D$ is a diffusion coefficient, $k$ is a reaction rate parameter, $c$ is the concentration, $kf(c)$ is the rate of reaction, and $c_0$ is the concentration at the boundary. Making the substitution $p = \dfrac{dc}{ds}$ gives (Finlayson, 1980, p. 92)

$$p\frac{dp}{dc} = \frac{k}{D}f(c)$$

Integrating gives $$\frac{p^2}{2} = \frac{k}{D}\int_{c(0)}^{c} f(c)dc$$

If the reaction is very fast, $c(0) \approx 0$ and the average reaction rate is related to $p(L)$. This variable is given by

$$p(L) = \left[ \frac{2k}{D} \int_0^{c(0)} f(c)\, dc \right]^{1/2}$$

Thus, the average reaction rate can be calculated without solving the complete problem.

**Linear Nonhomogeneous Differential Equations**

***Linear Differential Equations Right-Hand Member f(x) ≠ 0*** Again the specific remarks for $y'' + ay' + by = f(x)$ apply to differential equations of similar type but higher order. We shall discuss two general methods.

***Method of Undetermined Coefficients*** Use of this method is limited to equations exhibiting both constant coefficients and particular forms of the function $f(x)$. In most cases $f(x)$ will be a sum or product of functions of the type constant, $x^n$ ($n$ a positive integer), $e^{mx}$, cos $kx$, sin $kx$. When this is the case, the solution of the equation is $y = H(x) + P(x)$, where $H(x)$ is a solution of the homogeneous equations found by the method of the preceding subsection and $P(x)$ is a particular integral found by using the following table subject to these conditions: (1) When $f(x)$ consists of the sum of several terms, the appropriate form of $P(x)$ is the sum of the particular integrals corresponding to these terms individually. (2) When a term in any of the trial integrals listed is already a part of the homogeneous solution, the indicated form of the particular integral is multiplied by $x$.

**Form of Particular Integral**

| If $f(x)$ is | Then $P(x)$ is |
|---|---|
| $a$ (constant) | $A$ (constant) |
| $ax^n$ | $A_n x^n + A_{n-1} x^{n-1} + \cdots + A_1 x + A_0$ |
| $ae^{rx}$ | $Be^{rx}$ |
| $c \cos kx$<br>$d \sin kx$ | $A \cos kx + B \sin kx$ |
| $g\, x^n e^{rx} \cos kx$<br>$h\, x^n e^{rx} \sin kx$ | $(A_n x^n + \cdots + A_0)e^{rx} \cos kx + (B_n x^n + \cdots + B_0)e^{rx} \sin kx$ |

Since the form of the particular integral is known, the constants may be evaluated by substitution in the differential equation.

***Example*** $y'' + 2y' + y = 3e^{2x} - \cos x + x^3$. The characteristic equation is $(m + 1)^2 = 0$ so that the homogeneous solution is $y = (c_1 + c_2 x)e^{-x}$. To find a particular solution we use the trial solution from the table, $y = a_1 e^{2x} + a_2 \cos x + a_3 \sin x + a_4 x^3 + a_5 x^2 + a_6 x + a_7$. By substituting this in the differential equation and collecting and equating like terms, there results $a_1 = \frac{1}{3}$, $a_2 = 0$, $a_3 = -\frac{1}{2}$, $a_4 = 1$, $a_5 = -6$, $a_6 = 18$, and $a_7 = -24$. The solution is $y = (c_1 + c_2 x)e^{-x} + \frac{1}{3}e^{2x} - \frac{1}{2} \sin x + x^3 - 6x^2 + 18x - 24$.

***Method of Variation of Parameters*** This method is applicable to any linear equation. The technique is developed for a second-order equation but immediately extends to higher order. Let the equation be $y'' + a(x)y' + b(x)y = R(x)$, and let the solution of the homogeneous equation, found by some method, be $y = c_1 f_1(x) + c_2 f_2(x)$. It is now assumed that a particular integral of the differential equation is of the form $P(x) = uf_1 + vf_2$, where $u$ and $v$ are functions of $x$ to be determined by two equations. One equation results from the requirement that $uf_1 + vf_2$ satisfy the differential equation, and the other is a degree of freedom open to the analyst. The best choice proves to be

$$u' f_1 + v' f_2 = 0 \quad \text{and} \quad u' f_1' + v' f_2' = 0$$

Then

$$u' = \frac{du}{dx} = -\frac{f_2}{f_1 f_2' - f_2 f_1'} R(x)$$

$$v' = \frac{dv}{dx} = \frac{f_1}{f_1 f_2' - f_2 f_1'} R(x)$$

and since $f_1$, $f_2$, and $R$ are known, $u$, $v$ may be found by direct integration.

**Perturbation Methods** If the ordinary differential equation has a parameter that is small and is not multiplying the highest derivative, perturbation methods can give solutions for small values of the parameter.

***Example*** Consider the differential equation for reaction and diffusion in a catalyst; the reaction is second-order: $c'' = ac^2$, $c'(0) = 0$, $c(1) = 1$. The solution is expanded in the following Taylor series in $a$.

$$c(x, a) = c_0(x) + ac_1(x) + a^2 c_2(x) + \cdots$$

The goal is to find equations governing the functions $\{c_i(x)\}$ and solve them. Substitution into the equations gives the following equations:

$$c_0''(x) + ac_1''(x) + a^2 c_2''(x) + \cdots = a[c_0(x) + ac_1(x) + a^2 c_2(x) + \cdots]^2$$
$$c_0'(0) + ac_1'(0) + a^2 c_2'(0) + \cdots = 0$$
$$c_0(1) + ac_1(1) + a^2 c_2(1) + \cdots = 1$$

Like terms in powers of $a$ are collected to form the individual problems.

$$c_0'' = 0, c_0'(0) = 0, \quad c_0(1) = 1$$
$$c_1'' = c_0^2, c_1'(0) = 0, \quad c_1(1) = 0$$
$$c_2'' = 2c_0 c_1, c_2'(0) = 0, \quad c_2(1) = 0$$

The solution proceeds in turn.

$$c_0(x) = 1,\ c_1(x) = \frac{(x^2 - 1)}{2},\ c_2(x) = \frac{5 - 6x^2 + x^4}{12}$$

## SPECIAL DIFFERENTIAL EQUATIONS

See Olver et al. (2010) in General References.

**Euler's Equation** The linear equation $x^n y^{(n)} + a_1 x^{n-1} y^{n-1} + \cdots + a_{n-1} xy' + a_n y = R(x)$ can be reduced to a linear equation with constant coefficients by the change of variable $x = e^t$. To solve the homogeneous equation substitute $y = x^r$ into it, cancel the powers of $x$, which are the same for all terms, and solve the resulting polynomial for $r$. In case of multiple or complex roots there results the form $y = x^r (\log x)^r$ and $y = x^\alpha [\cos (\beta \log x) + i \sin (\beta \log x)]$.

**Bessel's Equation** The linear equation $x^2(d^2y/dx^2) + x(dy/dx) + (x^2 - p^2)y = 0$ is the Bessel equation of integer order. By series methods, not to be discussed here, this equation can be shown to have the solution

$$J_p(x) = \left(\frac{x}{2}\right)^p \sum_{k=0}^{\infty} \frac{(-1)^k (x/2)^{2k}}{k!(p + k)!}$$

(Bessel function of the first kind of order $p$) and

$$Y_p(x) = \frac{J_p(x) \cos (p\pi) - J_{-p}(x)}{\sin (p\pi)}$$

(Bessel function of the second kind) (replace right-hand side by limiting value if $p$ is an integer or zero).

The series converges for all $x$. Much of the importance of Bessel's equation and Bessel functions lies in the fact that the solutions of numerous linear differential equations can be expressed in terms of them.

**Legendre's Equation** The Legendre equation $(1 - x^2)y'' - 2xy' + n(n + 1)y = 0$, $n \geq 0$, has the solution $P_n$ for $n$ an integer.

The polynomials $P_n$ are the so-called Legendre polynomials, $P_0(x) = 1$, $P_1(x) = x$, $P_2(x) = \frac{1}{2}(3x^2 - 1)$, $P_3(x) = \frac{1}{2}(5x^3 - 3x)$, … For $n$ positive and not an integer, see Olver et al. (2010) in General References.

**Laguerre's Equation** The Laguerre equation $x(d^2y/dx^2) + (c - x)(dy/dx) - ay = 0$ is satisfied by the confluent hypergeometric function. See Olver et al. (2010) in General References.

**Hermite's Equation** The Hermite equation $y'' - 2xy' + 2ny = 0$ is satisfied by the Hermite polynomial of degree $n$, $y = AH_n(x)$, if $n$ is a positive integer or zero. $H_0(x) = 1$, $H_1(x) = 2x$, $H_2(x) = 4x^2 - 2$, $H_3(x) = 8x^3 - 12x$, $H_4(x) = 16x^4 - 48x^2 + 12$, $H_{r+1}(x) = 2xH_r(x) - 2rH_{r-1}(x)$.

**Chebyshev's Equation** The equation $(1 - x^2)y'' - xy' + n^2 y = 0$ for $n$ a positive integer or zero is satisfied by the $n$th Chebyshev polynomial $y = AT_n(x)$. $T_0(x) = 1$, $T_1(x) = x$, $T_2(x) = 2x^2 - 1$, $T_3(x) = 4x^3 - 3x$, $T_4(x) = 8x^4 - 8x^2 + 1$; $T_{r+1}(x) = 2xT_r(x) - T_{r-1}(x)$.

## PARTIAL DIFFERENTIAL EQUATIONS

The analysis of situations involving two or more independent variables frequently results in a partial differential equation.

***Example*** The equation $\partial T/\partial t = k(\partial^2 T/\partial x^2)$ represents the unsteady one-dimensional conduction of heat.

***Example*** The equation for the unsteady transverse motion of a uniform beam clamped at the ends is

$$\frac{\partial^4 y}{\partial x^4} + \frac{\rho}{EI} \frac{\partial^2 y}{\partial t^2} = 0$$

***Example*** The expansion of a gas behind a piston is characterized by the simultaneous equations

$$\frac{\partial u}{\partial t}+u\frac{\partial u}{\partial x}+\frac{c^2}{\rho}\frac{\partial \rho}{\partial x}=0 \quad \text{and} \quad \frac{\partial \rho}{\partial t}+u\frac{\partial u}{\partial x}+\rho\frac{\partial u}{\partial x}=0$$

The partial differential equation $\partial^2 f/(\partial x\,\partial y)=0$ can be solved by two integrations yielding the solution $f=g(x)+h(y)$, where $g(x)$ and $h(y)$ are arbitrary differentiable functions. This result is an example of the fact that the general solution of partial differential equations involves arbitrary functions in contrast to the solution of ordinary differential equations, which involve only arbitrary constants. A number of methods are available for finding the general solution of a partial differential equation. In most applications of partial differential equations, the general solution is of limited use. In such applications the solution of a partial differential equation must satisfy both the equation and certain auxiliary conditions called *initial* and/or *boundary* conditions, which are dictated by the problem. Examples of these include those in which the wall temperature is a fixed constant $T(x_0)=T_0$, there is no diffusion across a nonpermeable wall, and the like. In ordinary differential equations, these auxiliary conditions allow definite numbers to be assigned to the constants of integration.

**Partial Differential Equations of Second and Higher Order** Many of the applications to scientific problems fall naturally into partial differential equations of second order, although there are important exceptions in elasticity, vibration theory, and elsewhere. A second-order differential equation can be written as

$$a\frac{\partial^2 u}{\partial x^2}+b\frac{\partial^2 u}{\partial x\,\partial y}+c\frac{\partial^2 u}{\partial y^2}=f$$

where $a$, $b$, $c$, and $f$ depend upon $x$, $y$, $u$, $\partial u/\partial x$, and $\partial u/\partial y$. This equation is hyperbolic, parabolic, or elliptic, depending on whether the discriminant $b^2-4ac>0$, $=0$, or $<0$, respectively. Since $a$, $b$, $c$, and $f$ depend on the solution, the type of equation can be different at different $x$ and $y$ locations. If the equation is hyperbolic, discontinuities can be propagated. See Courant and Hilbert (1953, 1962) and LeVeque, R. J., *Numerical Methods for Conservation Laws*, Birkhäuser, Basel, Switzerland, 1992.

Phenomena of *propagation* such as vibrations are characterized by equations of "hyperbolic" type which are essentially different in their properties from other classes such as those which describe equilibrium (elliptic) or unsteady diffusion and heat transfer (parabolic). Prototypes are as follows:

***Elliptic*** Laplace's equation $\partial^2 u/\partial x^2+\partial^2 u/\partial y^2=0$ and Poisson's equation $\partial^2 u/\partial x^2+\partial^2 u/\partial y^2=g(x,y)$ do not contain the variable time explicitly and consequently represent equilibrium configurations. Laplace's equation is satisfied by static electric or magnetic potential at points free from electric charges or magnetic poles. Other important functions satisfying Laplace's equation are the velocity potential of the irrotational motion of an incompressible fluid, used in hydrodynamics; the steady temperature at points in a homogeneous solid; and the steady state of diffusion through a homogeneous body.

***Parabolic*** The heat equation $\partial T/\partial t=\partial^2 T/\partial x^2+\partial^2 T/\partial y^2$ represents nonequilibrium or unsteady states of heat conduction and diffusion.

***Hyperbolic*** The wave equation $\partial^2 u/\partial t^2=c^2(\partial^2 u/\partial x^2+\partial^2 u/\partial y^2)$ represents wave propagation of many varied types.

Quasilinear first-order differential equations are like

$$a\frac{\partial u}{\partial x}+b\frac{\partial u}{\partial y}=f$$

where $a$, $b$, and $f$ depend on $x$, $y$, and $u$, with $a^2+b^2\neq 0$. This equation can be solved using the method of characteristics, which writes the solution in terms of a parameter $s$, which defines a path for the characteristic.

$$\frac{dx}{ds}=a,\quad \frac{dy}{ds}=b,\quad \frac{du}{ds}=f$$

These equations are integrated from some initial conditions. For a specified value of $s$, the value of $x$ and $y$ shows the location where the solution is $u$. The equation is semilinear if $a$ and $b$ depend just on $x$ and $y$ (and not $u$), and the equation is linear if $a$, $b$, and $f$ all depend on $x$ and $y$, but not $u$. Such equations give rise to shock propagation, and conditions have been derived to deduce the presence of shocks. Courant and Hilbert (1953, 1962); Rhee, H. K., R. Aris, and N. R. Amundson, *First-Order Partial Differential Equations*, vol. 1, *Theory and Applications of Single Equations*, Prentice-Hall, Englewood Cliffs, N.J., 1986; and LeVeque (1992), ibid.

An example of a linear hyperbolic equation is the advection equation for flow of contaminants when the $x$ and $y$ velocity components are $u$ and $v$, respectively.

$$\frac{\partial c}{\partial t}+u\frac{\partial c}{\partial x}+v\frac{\partial c}{\partial y}=0$$

The equations for flow and adsorption in a packed bed or chromatography column give a quasilinear equation.

$$\phi\frac{\partial c}{\partial t}+\phi u\frac{\partial c}{\partial x}+(1-\phi)\frac{df}{dc}\frac{\partial c}{\partial t}=0$$

Here $n=f(c)$ is the relation between concentration on the adsorbent and fluid concentration.

The solution of problems involving partial differential equations often revolves about an attempt to reduce the partial differential equation to one or more ordinary differential equations. The solutions of the ordinary differential equations are then combined (if possible) so that the boundary conditions and the original partial differential equation are simultaneously satisfied. Three of these techniques are illustrated.

***Similarity Variables*** The physical meaning of the term "similarity" relates to internal similitude, or self-similitude. Thus, similar solutions in boundary-layer flow over a horizontal flat plate are those for which the horizontal component of velocity $u$ has the property that two velocity profiles located at different coordinates $x$ differ only by a scale factor. The mathematical interpretation of the term similarity is a transformation of variables carried out so that a reduction in the number of independent variables is achieved. There are essentially two methods for finding similarity variables, "separation of variables" (not the classical concept) and the use of "continuous transformation groups." The basic theory is available in Ames (1965).

***Example*** The equation $\partial\theta/\partial x=(A/y)(\partial^2\theta/\partial y^2)$ with the boundary conditions $\theta=0$ at $x=0$, $y>0$; $\theta=0$ at $y=\infty$, $x>0$; $\theta=1$ at $y=0$, $x>0$ represents the nondimensional temperature $\theta$ of a fluid moving past an infinitely wide flat plate immersed in the fluid. Turbulent transfer is neglected, as is molecular transport except in the $y$ direction. It is now assumed that the equation and the boundary conditions can be satisfied by a solution of the form $\theta=f(y/x^n)=f(u)$, where $\theta=0$ at $u=\infty$ and $\theta=1$ at $u=0$. The purpose here is to replace the independent variables $x$ and $y$ by the single variable $u$ when it is hoped that a value of $n$ exists which will allow $x$ and $y$ to be completely eliminated in the equation. In this case since $u=y/x^n$, there results after some calculation $\partial\theta/\partial x=-(nu/x)(d\theta/du)$, $\partial^2\theta/\partial y^2=(1/x^{2n})(d^2\theta/du^2)$, and when these are substituted in the equation, $-(1/x)nu\,(d\theta/du)=(1/x^{3n})(A/u)(d^2\theta/du^2)$. For this to be a function of $u$ only, choose $n=\frac{1}{3}$. There results $(d^2\theta/du^2)+(u^2/3A)(d\theta/du)=0$. Two integrations and use of the boundary conditions for this ordinary differential equation give the solution

$$\theta=\int_u^\infty \exp(-u^3/9A)\,du\Big/\int_0^\infty \exp(-u^3/9A)\,du$$

**Group Method** The type of transformation can be deduced using group theory. For a complete exposition, see Ames (1965) and Hill, J. M., *Differential Equations and Group Methods for Scientists and Engineers*, CRC Press, New York, 1992; a shortened version can be found in Finlayson (1980). Basically, a similarity transformation should be considered when one of the independent variables has no physical scale (perhaps it goes to infinity). The boundary conditions must also simplify (and combine) since each transformation leads to a differential equation with one fewer independent variable.

***Example*** A similarity variable is found for the problem

$$\frac{\partial c}{\partial t}=\frac{\partial}{\partial x}\left(\frac{D(c)}{D_0}\frac{\partial c}{\partial x}\right),\quad c(0,t)=1,\quad c(\infty,t)=0,\quad c(x,0)=0$$

Note that the length dimension goes to infinity, so there is no length scale in the problem statement; this is a clue to try a similarity transformation. The transformation examined here is

$$\bar{t}=a^\alpha t,\quad \bar{x}=a^\beta x,\quad \bar{c}=a^\gamma c$$

With this substitution, the equation becomes

$$a^{\alpha-\gamma}\frac{\partial \bar{c}}{\partial \bar{t}}=a^{2\beta-\gamma}\frac{\partial}{\partial \bar{x}}\left[\frac{D(a^{-\gamma}\bar{c})}{D_0}\frac{\partial \bar{c}}{\partial \bar{x}}\right]$$

Group theory says a system is conformally invariant if it has the same form in the new variables; here, that is

$$\gamma=0 \qquad \alpha-\gamma=2\beta-\gamma \qquad \text{or } \alpha=2\beta$$

The invariants are

$$\eta=\frac{x}{t^\delta},\quad \delta=\frac{\beta}{\alpha}$$

and the solution is

$$c(x,t) = f(\eta)t^{\gamma/\alpha}$$

We can take $\gamma = 0$ and $\delta = \beta/\alpha = ½$. Note that the boundary conditions combine because the point $x = \infty$ and $t = 0$ gives the same value of $\eta$ and the conditions on $c$ at $x = \infty$ and $t = 0$ are the same. We thus make the transformation

$$\eta = \frac{x}{\sqrt{4D_0 t}}, \quad c(x,t) = f(\eta)$$

The use of the 4 and $D_0$ makes the analysis below simpler. The result is

$$\frac{d}{d\eta}\left[\frac{D(c)}{D_0}\frac{df}{d\eta}\right] + 2\eta\frac{df}{d\eta} = 0, \quad f(0) = 1, \quad f(\infty) = 0$$

Thus, we solve a two-point boundary-value problem instead of a partial differential equation. When the diffusivity is constant, the solution is the error function, a tabulated function.

$$c(x,t) = 1 - \operatorname{erf}\eta = \operatorname{erfc}\eta$$

$$\operatorname{erf}\eta = \int_0^\eta e^{-\xi^2}\,d\xi \Big/ \int_0^\infty e^{-\xi^2}\,d\xi$$

**Separation of Variables** This powerful, well-utilized method is applicable in certain circumstances. It consists of assuming that the solution for a partial differential equation has the form $U = f(x)g(y)$. If it is then possible to obtain an ordinary differential equation on one side of the equation depending on only $x$ and on the other side on only $y$, the partial differential equation is said to be *separable* in the variables $x$ and $y$. If this is the case, one side of the equation is a function of $x$ alone and the other of $y$ alone. The two can be equal only if each is a constant, say, $\lambda$. Thus the problem has again been reduced to the solution of ordinary differential equations.

***Example*** Laplace's equation $\partial^2 V/\partial x^2 + \partial^2 V/\partial y^2 = 0$ plus the boundary conditions $V(0, y) = 0$, $V(l, y) = 0$, $V(x, \infty) = 0$, $V(x, 0) = f(x)$ represents the steady-state potential in a thin plate (in the $z$ direction) of infinite extent in the $y$ direction and of width $l$ in the $x$ direction. A potential $f(x)$ is impressed (at $y = 0$) from $x = 0$ to $x = 1$, and the sides are grounded. To obtain a solution of this boundary-value problem, assume $V(x, y) = f(x)g(y)$. Substitution in the differential equation yields $f''(x)g(y) + f(x)g''(y) = 0$ or $g''(y)/g(y) = -f''(x)/f(x) = \lambda^2$ (say). This system becomes $g''(y) - \lambda^2 g(y) = 0$ and $f''(y) + \lambda^2 f(y) = 0$. The solutions of these ordinary differential equations are, respectively, $g(y) = Ae^{\lambda y} + Be^{-\lambda y}$ and $f(x) = C \sin \lambda x + D \cos \lambda x$. Then $f(x)g(y) = (Ae^{\lambda y} + Be^{-\lambda y})(C \sin \lambda x + D \cos \lambda x)$. Now $V(0, y) = 0$ so that $f(0)g(y) = (Ae^{\lambda y} + Be^{-\lambda y})\ D \equiv 0$ for all $y$. Hence $D = 0$. The solution then has the form $\sin \lambda x\,(Ae^{\lambda y} + Be^{-\lambda y})$ where the multiplicative constant $C$ has been eliminated. Since $V(l, y) = 0$, $\sin \lambda l(Ae^{\lambda y} + Be^{-\lambda y}) \equiv 0$. Clearly the bracketed function of $y$ is not zero, for the solution would then be the identically zero solution. Hence $\sin \lambda l = 0$ or $\lambda_n = n\pi/l$, $n = 1, 2, \ldots$, where $\lambda_n = n$th eigenvalue.

The solution now has the form $\sin (n\pi x/l)(Ae^{n\pi y/l} + Be^{-n\pi y/l})$. Since $V(x, \infty) = 0$, $A$ must be taken to be zero because $e^y$ becomes arbitrarily large as $y \to \infty$. The solution then reads $B_n \sin (n\pi x/l)e^{-n\pi y/l}$, where $B_n$ is the multiplicative constant. The differential equation is linear and homogeneous so that $\sum_{n=1}^{\infty} B_n e^{-n\pi y/l} \sin (n\pi x/l)$ is also a solution. Satisfaction of the last boundary condition is ensured by taking

$$B_n = \frac{2}{l}\int_0^l f(x) \sin (n\pi x/l)\,dx = \text{Fourier sine coefficients of } f(x)$$

Further, convergence and differentiability of this series are established quite easily. Thus the solution is

$$V(x,y) = \sum_{n=1}^{\infty} B_n e^{-n\pi y/l} \sin \frac{n\pi x}{l}$$

***Example*** The diffusion problem in a slab of thickness $L$

$$\frac{\partial c}{\partial t} = D\frac{\partial^2 c}{\partial x^2}, \quad c(0,t) = 1, \quad c(L,t) = 0, \quad c(x,0) = 0$$

can be solved by separation of variables. First transform the problem so that the boundary conditions are homogeneous (having zeros on the right-hand side). Let

$$c(x,t) = 1 - \frac{x}{L} + u(x,t)$$

Then $u(x, t)$ satisfies

$$\frac{\partial u}{\partial t} = D\frac{\partial^2 u}{\partial x^2}, \quad u(x,0) = \frac{x}{L} - 1, \quad u(0,t) = 0, \quad u(L,t) = 0$$

Assume a solution of the form $u(x, t) = X(x)T(t)$, which gives

$$\frac{1}{DT}\frac{dT}{dt} = \frac{1}{X}\frac{d^2X}{dx^2}$$

Since both sides are constant, this gives the following ordinary differential equations to solve:

$$\frac{1}{DT}\frac{dT}{dt} = -\lambda, \quad \frac{1}{X}\frac{d^2X}{dx^2} = -\lambda$$

The solution of these is

$$T = Ae^{-\lambda Dt} \qquad X = B\cos\sqrt{\lambda}\,x + E\sin\sqrt{\lambda}\,x$$

The combined solution for $u(x, t)$ is

$$u = A(B\cos\sqrt{\lambda}\,x + E\sin\sqrt{\lambda}\,x)\,e^{-\lambda Dt}$$

Apply the boundary condition that $u(0, t) = 0$ to give $B = 0$. Then the solution is

$$u = A(\sin\sqrt{\lambda}\,x)e^{-\lambda Dt}$$

where the multiplicative constant $E$ has been eliminated. Apply the boundary condition at $x = L$.

$$0 = A(\sin\sqrt{\lambda}\,L)e^{-\lambda Dt}$$

This can be satisfied by choosing $A = 0$, which gives no solution. However, it can also be satisfied by choosing $\lambda$ such that

$$\sin\sqrt{\lambda}\,L = 0, \sqrt{\lambda}\,L = n\pi$$

Thus

$$\lambda = \frac{n^2\pi^2}{L^2}$$

The combined solution can now be written as

$$u = A\left(\frac{\sin n\pi x}{L}\right)e^{-n^2\pi^2 Dt/L^2}$$

Since the initial condition must be satisfied, we use an infinite series of these functions.

$$u = \sum_{n=1}^{\infty} A_n\left(\frac{\sin n\pi x}{L}\right)e^{-n^2\pi^2 Dt/L^2}$$

At $t = 0$, we satisfy the initial condition.

$$\frac{x}{L} - 1 = \sum_{n=1}^{\infty} A_n\left(\frac{\sin n\pi x}{L}\right)$$

This is done by multiplying the equation by

$$\frac{\sin m\pi x}{L}$$

and integrating over $x$: $0 \to L$. (This is the same as minimizing the mean square error of the initial condition.) This gives

$$\frac{A_m L}{2} = \int_0^L\left(\frac{x}{L} - 1\right)\sin\frac{m\pi x}{L}\,dx$$

which completes the solution.

**Integral-Transform Method** A number of integral transforms are used in the solution of differential equations. Only one, the Laplace transform, is discussed here [ for others, see Integral Transforms (Operational Methods)].

The one-sided Laplace transform indicated by $L[f(t)]$ is defined by the equation $L[f(t)] \int_0^\infty f(t)e^{-st}dt$. It has numerous important properties. The ones of interest here are $L[f'(t)] = sL[f(t)] - f(0)$ $L[f''(t)] = s^2L[f(t)] - sf(0) - f'(0)$; $L[f^{(n)}(t)] = s^nL[f(t)] - s^{n-1}f(0) - s^{n-2}f'(0) - \cdots - f^{(n-1)}(0)$ for ordinary derivatives. For partial derivatives an indication of which variable is being transformed avoids confusion. Thus, if

$$y = y(x,t), L_t\left[\frac{\partial y}{\partial t}\right] = sL[y(x,t)] - y(x,0)$$

whereas

$$L_t\left[\frac{\partial y}{\partial x}\right] = \frac{dL_t[y(x,t)]}{dx}$$

since $L[y(x, t)]$ is "really" only a function of $x$. Otherwise the results are similar. These facts coupled with the linearity of the transform, i.e., $L[af(t) + bg(t)] = aL[f(t)] + bL[g(t)]$, make it a useful device in solving some linear differential equations. Its use reduces the solution of ordinary differential equations to the solution of algebraic equations for $L[y]$. the inverse transform must be obtained either from tables or by use of complex inversion methods.

***Example*** The equation $\partial c/\partial t = D(\partial^2 c/\partial x^2)$ represents the diffusion in a semi-infinite medium, $x \geq 0$. Under the boundary conditions $c(0, t) = c_0$ and $c(x, 0) = 0$, find a solution of the diffusion equation. By taking the Laplace transform of both sides with respect to $t$,

$$\int_0^\infty e^{-st}\frac{\partial^2 c}{\partial x^2}dt = \frac{1}{D}\int_0^\infty e^{-st}\frac{\partial c}{\partial t}dt$$

or

$$\frac{d^2F}{dx^2} = (1/D)sF - c(x,0) = \frac{sF}{D}$$

where $F(x, s) = L_t[c(x, t)]$. Hence

$$\frac{d^2F}{dx^2} - \left(\frac{s}{D}\right)F = 0$$

The other boundary condition transforms into $F(0, s) = c_0/s$. Finally the solution of the ordinary differential equation for $F$ subject to $F(0, s) = c_0/s$ and $F$ remains finite as $x \to \infty$ is $F(x,s) = (c_0/s)e^{-\sqrt{s/D}x}$. Reference to a table shows that the function having this as its Laplace transform is

$$c(x,t) = c_0\left[1 - \frac{2}{\sqrt{\pi}}\int_0^{\pi/2\sqrt{Dt}} e^{-u^2}du\right] = C_0 \operatorname{erfc}\left(\frac{x}{\sqrt{4Dt}}\right)$$

This is the same solution obtained above by the group method.

**Matched-Asymptotic Expansions** Sometimes the coefficient in front of the highest derivative is a small number. Special perturbation techniques can then be used, provided the proper scaling laws are found. See Holmes, M. H., *Introduction to Perturbation Methods*, 2d ed., Springer, New York, 2013.

# DIFFERENCE EQUATIONS

**REFERENCES:** Elaydi, Saber, *An Introduction to Difference Equations*, 3d ed., Springer-Verlag, New York, 2005; Kelley, W. G., and A. C. Peterson, *Difference Equations: An Introduction with Applications*, 2d ed., Harcourt/Academic, San Diego, Calif., 2001.

Some models have independent variables that do not vary continuously, but have meaning only for discrete values. Stagewise processes such as distillation, staged extraction systems, absorption columns, and continuous stirred tank reactors (CSTRs) are such processes. The dependent variable varies between stages, and the independent variable is the integral number of the stage. Difference equations arise in discrete models of environmental problems (see Logan and Wolesensky). Difference equations also arise in the solution of partial differential equations using the finite difference method, and those are treated below (Numerical Analysis and Approximate Methods). Examined here are solution methods applicable to the chemical engineering problems; for more detailed information see the references. The methods for difference equations mirror those for differential equations. In particular, find complementary solution and then a particular solution. The order of the difference equation is the difference between the largest and smallest arguments.

Consider the countercurrent cascade shown in Fig. 3-45. We let $y_i$ be the ratio of the mass of solute to mass of solvent in the $i$th cell; $x_i$ is the ratio of mass of solute to mass of carrier solvent in the $i$th cell. For illustration we take the equilibrium relation as linear

$$y_i = Kx_i$$

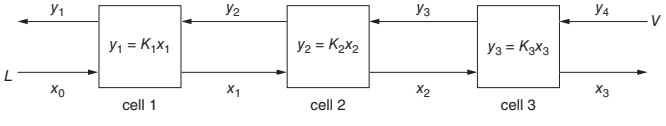

**FIG. 3-45** Countercurrent cascade.

A material balance on the $i$th stage gives

$$Lx_{i-1} + Vy_{i+1} - Lx_i - Vy_i = 0$$

Using the equilibrium relation transforms this equation to the form

$$(L/K)y_{i-1} + Vy_{i+1} - (L/K)y_i - Vy_i = 0$$

or

$$y_{i+1} - [(L/VK) + 1]y_i + (L/VK)y_{i-1} = 0$$

With $\alpha = L/VK$ the final form of the difference equation is $y_{i+1} - (\alpha + 1)y_i + \alpha y_{i-1} = 0$. The solution is obtained by trying the general form $y_i = r^i$. This gives the characteristic equation $r^2 - (\alpha + 1)r + \alpha = 0$. One root is $r = 1$, and call the other root $\beta$. The solution is then $y_i = A + B\,\beta^i$. This completes the complementary solution. The number of units is taken as $N$. The particular solution is found by choosing $A$ and $B$ to fit boundary conditions. Here they are taken as the inlet feed composition $x_0$ and the inlet solvent composition $y_{N+1}$. Using $y_0 = Kx_0$, we obtain two equations for $A$ and $B$. The solutions are $A = Kx_0 - B$ and $B = (Kx_0 - y_{N+1})/(1 - \beta^{N+1})$. The exit concentration is $y_1 = A + B\,\beta$.

**Nonlinear Difference Equations: Riccati Difference Equation** The Riccati equation $y_{i+1}y_i + ay_{i+1} + by_i + c = 0$ is a nonlinear difference equation which can be solved by reduction to linear form. Set $y = z + h$. The equation becomes $z_{i+1}z_i + (h + a)z_{i+1} + (h + b)z_i + h^2 + (a + b)h + c = 0$. If $h$ is selected as a root of $h^2 + (a + b)h + c = 0$ and the equation is divided by $z_{i+1}z_i$, there results $(h + b)/z_{i+1} + (h + a)/z_i + 1 = 0$. This is a linear equation with constant coefficients for $w_i = 1/z_i$. The solution is

$$\frac{1}{y_i - h} = K\left[-\frac{a+h}{b+h}\right]^i - \frac{1}{(a+h)+(b+h)}$$

where $K$ is a constant chosen to fit conditions at one point. This equation is obtained in distillation problems, among others, in which the number of theoretical plates is required. If the relative volatility is assumed to be constant, the plates are theoretically perfect, and the molal liquid and vapor rates are constant, then a material balance around the $n$th plate of the enriching section yields a Riccati difference equation.

# INTEGRAL EQUATIONS

**REFERENCES:** Davis, H. T., *Introduction to Nonlinear Differential and Integral Equations*, Dover, New York, 2010; Statgold, I., and M. J. Holst, *Green's Functions and Boundary Value Problems*, 3d ed., Interscience, New York, 2011.

An integral equation is any equation in which the unknown function appears under the sign of integration and possibly outside the sign of integration. If derivatives of the dependent variable appear elsewhere in the equation, the equation is said to be *integrodifferential*.

## CLASSIFICATION OF INTEGRAL EQUATIONS

Volterra's integral equations have an integral with a variable limit, whereas Fredholm's integral equations have a fixed limit. The Volterra equation of the second kind is

$$u(x)=f(x)+\lambda\int_a^x K(x,t)u(t)dt$$

whereas a Volterra equation of the first kind is

$$u(x)=\lambda\int_a^x K(x,t)u(t)dt$$

Equations of the first kind are very sensitive to solution errors so that they present severe numerical problems. Volterra equations are similar to initial-value problems.

A Fredholm equation of the second kind is

$$u(x)=f(x)+\lambda\int_a^b K(x,t)u(t)dt$$

whereas a Fredholm equation of the first kind is

$$u(x)=\int_a^b K(x,t)u(t)dt$$

The limits of integration are fixed, and these problems are analogous to boundary value problems.

An eigenvalue problem is a homogeneous equation of the second kind, and solutions exist only for certain $\lambda$.

$$u(x)=\lambda\int_a^b K(x,t)u(t)dt$$

An example of a Volterra equation is the heat conduction problem in a semi-infinite domain.

$$\rho C_p\frac{\partial T}{\partial t}=k\frac{\partial^2 T}{\partial x^2}\qquad 0\le x<\infty, t>0$$

$$T(x,0)=0\qquad \frac{\partial T}{\partial x}(0,t)=-g(t)$$

$$\lim_{x\to 0}T(x,t)=0\qquad \lim_{x\to\infty}\frac{\partial T}{\partial x}(x,t)=0$$

If this is solved by using Fourier transforms [see Integral Transforms (Operational Methods)], the solution is

$$T(x)=\frac{1}{k}\int_0^1 G(x,y)Q(y)dy$$

$$T(x,t)=\frac{1}{\sqrt{\pi}}\int_0^1 g(s)\frac{1}{\sqrt{t-s}}e^{-x^2/4(t-s)}ds$$

Integral equations can arise from the formulation of a problem by using Green's function. The equation governing heat conduction with a variable heat generation rate is represented in differential form as

$$\frac{d^2T}{dx^2}=\frac{Q(x)}{k}\qquad T(0)=T(1)=0$$

In integral form the same problem is

$$T(x)=\frac{1}{k}\int_0^1 G(x,y)Q(y)dy$$

$$G(x,y)=\begin{cases}-x(1-y) & x\le y\\ -y(1-x) & y\le x\end{cases}$$

The Poisson equation governs electric charges

$$\nabla^2\Psi=-4\pi\rho$$

and the formulation as an integral equation is

$$\Psi(\mathbf{r})=\int_V \rho(r_0)G(r,r_0)\,dV_0$$

where Green's function in three dimensions is

$$G(\mathbf{r},\mathbf{r}_0)=\frac{1}{r},\ r=\sqrt{(x-x_0)^2+(y-y_0)^2+(z-z_0)^2}$$

and in two dimensions is

$$G(\mathbf{r},\mathbf{r}_0)=-2\ln r,\ r=\sqrt{(x-x_0)^2+(y-y_0)^2}$$

See the references for other examples.

Integral equations can be solved numerically, too. The methods are analogous to the usual methods for integrating differential equations (Runge-Kutta, predictor-corrector, Adams methods, etc.). Explicit methods are fast and efficient until the time step is very small, to meet the stability requirements. Then implicit methods are used, even though sets of simultaneous algebraic equations must be solved. The major part of the calculation is the evaluation of integrals, however, so that the added time to solve the algebraic equations is not excessive. Thus, implicit methods tend to be preferred. Volterra equations of the first kind are not well posed, and small errors in the solution can have disastrous consequences. The boundary element method uses Green's functions and integral equations to solve differential equations. See Brebbia, C. A., and J. Dominguez, *Boundary Elements—An Introductory Course*, 2d ed., Computational Mechanics Publications, Southhampton, UK, 1992; and Mackerle, J., and C. A. Brebbia, eds., *Boundary Element Reference Book*, Springer Verlag, Berlin, 1988.

# INTEGRAL TRANSFORMS (OPERATIONAL METHODS)

**REFERENCES:** Davies, B., *Integral Transforms and Their Applications*, 3d ed., Springer, New York, 2002; Debnath, L., and D. Bhatta, *Integral Transforms and Their Applications*, 3d ed., Chapman and Hall/CRC, New York, 2014; Duffy, D. G., *Transform Methods for Solving Partial Differential Equations*, Chapman & Hall/CRC, New York, 2nd ed., 2004; see also references for Differential Equations.

The term *operational method* implies a procedure of solving differential and difference equations by which the boundary or initial conditions are automatically satisfied in the course of the solution. The technique offers a very powerful tool in the applications of mathematics, but it is limited to linear problems.

Most integral transforms are special cases of the equation $g(s)=\int_a^b f(t)K(s,t)dt$ in which $g(s)$ is said to be the *transform* of $f(t)$ and $K(s,t)$ is called the *kernel* of the transform. A tabulation of the more important kernels and the interval $(a,b)$ of applicability follows.

| Name of transform | $(a,b)$ | $K(s,t)$ |
|---|---|---|
| Laplace | $(0,\infty)$ | $e^{-st}$ |
| Fourier | $(-\infty,\infty)$ | $\frac{1}{\sqrt{2\pi}}e^{-ist}$ |
| Fourier cosine | $(0,\infty)$ | $\sqrt{\frac{2}{\pi}}\cos st$ |
| Fourier sine | $(0,\infty)$ | $\sqrt{\frac{2}{\pi}}\sin st$ |

## LAPLACE TRANSFORM

The Laplace transform of a function $f(t)$ is defined by $F(s) = L\{f(t)\} = \int_0^\infty e^{-st} f(t)\,dt$, where $s$ is a complex variable. Note that the transform is an improper integral and therefore may not exist for all continuous functions and all values of $s$. We restrict consideration to those values of $s$ and those functions $f$ for which this improper integral converges. The Laplace transform is used in process control (see Sec. 8).

The function $L[f(t)] = g(s)$ is called the *direct transform*, and $L^{-1}[g(s)] = f(t)$ is called the *inverse transform*. Both the direct and the inverse transforms are tabulated for many often recurring functions. In general,

$$L^{-1}[g(s)] = \frac{1}{2\pi i}\int_{\alpha-i\infty}^{\alpha+i\infty} e^{st} g(s)\,ds$$

and to evaluate this integral requires a knowledge of complex variables, the theory of residues, and contour integration.

A function is said to be *piecewise continuous* on an interval if it has only a finite number of finite (or jump) discontinuities. A function $f$ on $0 < t < \infty$ is said to be of *exponential growth at infinity* if there exist constants $M$ and $\alpha$ such that $|f(t)| \le Me^{\alpha t}$ for sufficiently large $t$.

**Sufficient Conditions for the Existence of the Laplace Transform** Suppose $f$ is a function which is (1) piecewise continuous on every finite interval $0 < t < T$, (2) of exponential growth at infinity, and (3) for which $\int_0^\delta |f(t)|\,dt$ exists (finite) for every finite $\delta > 0$. Then the Laplace transform of $f$ exists for all complex numbers $s$ with a sufficiently large real part.

Note that condition 3 is automatically satisfied if $f$ is assumed to be piecewise continuous on every finite interval $0 \le t < T$. The function $f(t) = t^{-1/2}$ is not piecewise continuous on $0 \le t < T$ but satisfies conditions 1 to 3.

Let $\Lambda$ denote the class of all functions on $0 < t < \infty$ which satisfy conditions 1 to 3.

***Example*** Let $f(t)$ be the Heaviside step function at $t = t_0$; that is, $f(t) = 0$ for $t \le t_0$ and $f(t) = 1$ for $t > t_0$. Then

$$L\{f(t)\} = \int_{t_0}^\infty e^{-st}\,dt = \lim_{T\to\infty}\int_{t_0}^T e^{-st}\,dt = \lim_{T\to\infty}\frac{1}{s}(e^{-st_0} - e^{-sT}) = \frac{e^{-st_0}}{s} \qquad \text{provided } s > 0$$

***Example*** Let $f(t) = e^{\alpha t}$, $t \ge 0$, where $a$ is a real number. Then $L\{e^{\alpha t}\} = \int_0^\infty e^{-(s-a)t}\,dt = 1/(s-a)$ provided Re $s > a$.

**Properties of the Laplace Transform**

1. The Laplace transform is a linear operator: $L\{af(t) + bg(t)\} = aL\{f(t)\} + bL\{g(t)\}$ for any constants $a$ and $b$ and any two functions $f$ and $g$ whose Laplace transforms exist.

2. The Laplace transform of a real-valued function is real for real $s$. If $f(t)$ is a complex-valued function $f(t) = u(t) + i\upsilon(t)$, where $u$ and $\upsilon$ are real, then $L\{f(t)\} = L\{u(t)\} + iL\{\upsilon(t)\}$. Thus $L\{u(t)\}$ is the real part of $L\{f(t)\}$, and $L\{\upsilon(t)\}$ is the imaginary part of $L\{f(t)\}$.

3. The Laplace transform of a function in the class $\Lambda$ has derivatives of all orders, and $L\{t^k f(t)\} = (-1)^k\, d^k F(s)/ds^k$, $k = 1, 2, 3, \ldots$, where $F(s)$ is the Laplace transform of $f(t)$.

***Example*** $\int_0^\infty e^{st} \sin at\,dt = \frac{a}{s^2 + a^2}, s > 0.$

By property 3, $L\{t \sin at\} = \int_0^\infty e^{-st} t \sin at\,dt = \frac{2as}{(s^2 + a^2)^2}$

***Example*** By applying property 3 with $f(t) = 1$ and using the preceding results, we obtain

$$L\{t^k\} = (-1)^k \frac{d^k}{ds^k}\left(\frac{1}{s}\right) = \frac{k!}{s^{k+1}}$$

provided Re $s > 0$ for $k = 1, 2, \ldots$. Similarly, we obtain

$$L\{t^k\, e^{at}\} = (-1)^k \frac{d^k}{ds^k}\left(\frac{1}{s-a}\right) = \frac{k!}{(s-a)^{k+1}}$$

4. Frequency-shift property (or, equivalently, the transform of an exponentially modulated function). If $F(s)$ is the Laplace transform of a function $f(t)$ in class $\Lambda$, then for any constant $a$, $L\{e^{at} f(t)\} = F(s - a)$.

***Example*** $L\{te^{-at}\} = \frac{1}{(s+a)^2} \qquad (s > 0).$

5. Time-shift property. Let $u(t - a)$ be the unit step function at $t = a$. Then $L\{f(t-a)u(t-a)\} = e^{-as}F(s)$.

6. Transform of a derivative. Let $f$ be a differentiable function such that both $f$ and $f'$ belong to the class $\Lambda$. Then $L\{f'(t)\} = sF(s) - f(0)$.

7. Transform of a higher-order derivative. Let $f$ be a function which has continuous derivatives up to order $n$ on $(0, \infty)$, and suppose that $f$ and its derivatives up to order $n$ belong to the class $\Lambda$. Then $L\{f^{(j)}(t)\} = s^j F(s) - s^{j-1} f(0) - s^{j-2} f'(0) - \cdots - sf^{(j-2)}(0) - f^{(j-1)}(0)$ for $j = 1, 2, \ldots, k$.

***Example*** $L\{f''(t)\} = s^2 L\{f(t)\} - sf(0) - f'(0)$

***Example*** Solve $y'' + y = 2e^t, y(0) = y'(0) = 2$. $L[y''] = -y'(0) - sy(0) + s^2 L[y] = -2 - 2s + s^2 L[y]$. Thus

$$-2 - 2s + s^2 L[y] + L[y] = 2L[e^t] = \frac{2}{s-1}$$

$$L[y] = \frac{2s^2}{(s-1)(s^2+1)} = \frac{1}{s-1} + \frac{s}{s^2+1} + \frac{1}{s^2+1}$$

Hence $y = e^t + \cos t + \sin t$.

A short table (Table 3-2) of very common Laplace transforms and inverse transforms follows. The references and computer programs include more detailed tables. In Mathematica, the command "Laplace Transform[cosh[a*t],t,s]" returns $s/(s^2 - a^2)$. **NOTE:** $\Gamma(n+1) = \int_0^\infty x^n e^{-x}\,dx$ (gamma function); $J_n(t)$ = Bessel function of the first kind of order $n$.

8. $L\left[\int_a^t f(t)\,dt\right] = \frac{1}{s}L[f(t)] + \frac{1}{s}\int_a^0 f(t)\,dt$

**TABLE 3-2 Laplace Transforms**

| $f(t)$ | $g(s)$ | $f(t)$ | $g(s)$ |
|---|---|---|---|
| 1 | $1/s$ | $e^{-at}(1 - at)$ | $\frac{s}{(s+a)^2}$ |
| $t^n$, $(n = +\text{ integer})$ | $\frac{n!}{s^{n+1}}$ | $\frac{t \sin at}{2a}$ | $\frac{s}{(s^2+a^2)^2}$ |
| $t^n$, $(n \ne +\text{ integer})$ | $\frac{\Gamma(n+1)}{s^{n+1}}$ | $\frac{1}{2a^2}\sin at \sinh at$ | $\frac{s}{s^4 + 4a^4}$ |
| $\cos at$ | $\frac{s}{s^2+a^2}$ | $\cos at \cosh at$ | $\frac{s^3}{s^2 + 4a^4}$ |
| $\sin at$ | $\frac{a}{s^2+a^2}$ | $\frac{1}{2a}(\sinh at + \sin at)$ | $\frac{s^2}{s^4 - a^4}$ |
| $\cosh at$ | $\frac{s}{s^2-a^2}$ | ½(cosh $at$ + cos $at$) | $\frac{s^3}{s^4 - a^4}$ |
| $\sinh at$ | $\frac{a}{s^2-a^2}$ | $\frac{\sin at}{t}$ | $\tan^{-1}\frac{a}{s}$ |
| $e^{-at}$ | $\frac{1}{s+a}$ | $J_0(at)$ | $\frac{1}{\sqrt{s^2+a^2}}$ |
| $e^{-bt}\cos at$ | $\frac{s+b}{(s+b)^2+a^2}$ | $na^n\frac{J_n(at)}{t}$ | $(\sqrt{s^2+a^2} - s)^n (n > 0)$ |
| $e^{-bt}\sin at$ | $\frac{a}{(s+b)^2+a^2}$ | $J_0(2\sqrt{at})$ | $\frac{1}{s}e^{-a/s}$ |
| $\text{erfc}\frac{k}{2\sqrt{t}}$ | $\frac{1}{s}e^{-k\sqrt{s}}$ | $t^{n-1}e^{at}$ | $\frac{\Gamma(n)}{(s-a)^n} (n > 0)$ |

***Example*** Find $f(t)$ if $L[f(t)] = \frac{1}{s^2}\left[\frac{1}{s^2 - a^2}\right]$. $L\left[\frac{1}{a}\sinh at\right] = \frac{1}{s^2 - a^2}$.

Therefore $f(t) = \int_0^t\left[\int_0^t \frac{1}{a}\sinh\ at\ dt\right]dt = \frac{1}{a^2}\left[\frac{\sinh\ at}{a} - t\right]$.

9. $L\left[\frac{f(t)}{t}\right] = \int_s^\infty g(s)\,ds \qquad L\left[\frac{f(t)}{t^k}\right] = \underbrace{\int_s^\infty \cdots \int_s^\infty}_{k \text{ integrals}} g(s)(ds)^k$

***Example*** $L\left[\frac{\sin at}{t}\right] = \int_s^\infty L[\sin\ at]\,ds = \int_s^\infty \frac{a\ ds}{s^2 + a^2} = \cot^{-1}\frac{s}{a}$

10. The unit step function

$$u(t-a) = \begin{cases} 0 & t < a \\ 1 & t > a \end{cases} \qquad L[u(t-a)] = \frac{e^{-as}}{s}$$

11. The unit impulse function is

$$\delta(a)=u'(t-a)=\begin{cases}\infty & \text{at } t=a\\ 0 & \text{elsewhere}\end{cases}\qquad L[u'(t-a)]=e^{-as}$$

12. $L^{-1}[e^{-as}g(s)]=f(t-a)u(t-a)$ (second shift theorem).
13. If $f(t)$ is periodic of period $b$, that is, $f(t+b)=f(t)$, then

$$L[f(t)]=\left[\frac{1}{1-e^{-bs}}\right]\int_0^b e^{-st}f(t)\,dt$$

***Example*** The partial differential equations relating gas composition to position and time in a gas chromatograph are $\partial y/\partial n+\partial x/\partial\theta=0$ and $\partial y/\partial n=x-y$, where $x=mx'$, $n=(k_GaP/G_m)h$, $\theta=(mk_GaP/\rho_B)t$ and $G_M=$ molar velocity, $y=$ mole fraction of the component in the gas phase, $\rho_B=$ bulk density, $h=$ distance from entrance, $P=$ pressure, $k_G=$ mass-transfer coefficient, and $m=$ slope of the equilibrium line. These equations are equivalent to $\partial^2y/\partial n\,\partial\theta+\partial y/\partial n+\partial y/\partial\theta=0$, where the boundary conditions considered here are $y(0,\theta)=0$ and $x(n,0)=y(n,0)+(\partial y/\partial n)(n,0)=\delta(0)$ (see property 11). The problem is conveniently solved by using the Laplace transform of $y$ with respect to $n$; write $g(s,\theta)=\int_0^\infty e^{-ns}y(n,\theta)\,dn$. Operating on the partial differential equation gives $s(dg/d\theta)-(\partial y/\partial\theta)(0,\theta)+sg-y(0,\theta)+dg/d\theta=0$ or $(s+1)(dg/d\theta)+sg=(\partial y/\partial\theta)(0,\theta)+y(0,\theta)=0$. The second boundary condition gives $g(s,0)+sg(s,0)-y(0,0)=1$ or $g(s,0)+sg(s,0)=1$ ($L[\delta(0)]=1$). A solution of the ordinary differential equation for $g$ consistent with this second condition is

$$g(s,\theta)=\frac{1}{s+1}e^{-s\theta/(s+1)}$$

Inversion of this transform gives the solution $y(n,\theta)=e^{-(n+\theta)}I_0(2\sqrt{n\theta})$ where $I_0=$ zero-order Bessel function of an imaginary argument. For large $u$, $I_n(u)\sim e^u/\sqrt{2\pi u}$. For large $n$,

$$y(n,\theta)\sim\frac{\exp[-(\sqrt{\theta}-\sqrt{n})^2]}{2\pi^{1/2}(n\theta)^{1/4}}$$

or for sufficiently large $n$, the peak concentration occurs near $\theta=n$.

Other applications of Laplace transforms are given under Differential Equations.

## CONVOLUTION INTEGRAL

The convolution integral of two functions $f(t)$ and $r(t)$ is $x(t)=f(t)*r(t)=\int_0^t f(\tau)r(t-\tau)d\tau$.

***Example*** $t*\sin t=\int_0^t\tau\sin(t-\tau)\,d\tau=t-\sin t$.

$$L[f(t)]L[h(t)]=L[f(t)*h(t)]$$

## FOURIER TRANSFORM

**REFERENCES:** https://en.wikipedia.org/wiki/Fourier_transform#Tables_of_important_Fourier_transforms; Varma and Morbidelli (1997), see General References.

The Fourier transform is given by

$$F[f(t)]=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}f(t)^{-ist}\,dt=g(s)$$

and its inverse by

$$F^{-1}[g(s)]=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}g(s)e^{ist}\,dt=f(t)$$

In brief, the condition for the Fourier transform to exist is that $\int_{-\infty}^{\infty}|f(t)|\,dt<\infty$, although certain functions may have a Fourier transform even if this is violated.

***Example*** The function $f(t)=\begin{cases}1 & -a\le t\le a\\ 0 & \text{elsewhere}\end{cases}$ has $F[f(t)]=\int_{-a}^{a}e^{-ist}dt$

$$=\int_0^a e^{ist}\,dt+\int_0^a e^{-ist}\,dt=2\int_0^a\cos st\,dt=\frac{2\sin sa}{s}$$

**Properties of the Fourier Transform** Let $F[f(t)]=g(s)$; $F^{-1}[g(s)]=f(t)$.

1. $F[f^{(n)}(t)]=(is)^nF[f(t)]$.
2. $F[af(t)+bh(t)]=aF[f(t)]+bF[h(t)]$.
3. $F[f(-t)]=g(-s)$.
4. $F[f(at)]=\frac{1}{a}g\left(\frac{s}{a}\right),\quad a>0$.
5. $F[e^{-iwt}f(t)]=g(s+w)$.
6. $F[f(t+t_1)]=e^{ist_1}g(s)$.
7. $F[f(t)]=G(is)+G(-is)$ if $f(t)=f(-t)$ ($f$ even)
   $F[f(t)]=G(is)-G(-is)$ if $f(t)=-f(-t)$ ($f$ odd)

where $G(s)=L[f(t)]$. This result allows the use of the Laplace transform tables to obtain the Fourier transforms.

***Example*** Find $F[e^{-a|t|}]$ by property 7. Now $e^{-a|t|}$ is even. So $L[e^{-at}]=1/(s+a)$. Therefore, $F[e^{-a|t|}]=1/(is+a)+1/(-is+a)=2a/(s^2+a^2)$.

## FOURIER COSINE TRANSFORM

The Fourier cosine transform is given by

$$F_c[f(t)]=g(s)=\sqrt{\frac{2}{\pi}}\int_0^\infty f(t)\cos st\,dt$$

and its inverse by

$$F_c^{-1}[g(s)]=f(t)=\sqrt{\frac{2}{\pi}}\int_0^\infty g(s)\cos st\,ds$$

The Fourier sine transform $F_s$ is obtainable by replacing the cosine by the sine in these integrals. They can be used to solve linear differential equations; see the transform references.

# MATRIX ALGEBRA AND MATRIX COMPUTATIONS

**REFERENCES:** Anton, H., and C. Rorres, *Elementary Linear Algebra with Applications*, 9th ed., Wiley, New York, 2004; Bernstein, D. S., *Matrix Mathematics: Theory, Facts, and Formulas with Application to Linear Systems Theory*, 2d ed., Princeton University Press, Princeton, N.J., 2009.

## MATRIX ALGEBRA

**Matrices** A rectangular array of $mn$ quantities, arranged in $m$ rows and $n$ columns,

$$A=(a_{ij})=\begin{bmatrix}a_{11} & \cdots & a_{1n}\\ a_{21} & \cdots & a_{2n}\\ \vdots & & \\ a_{m1} & & a_{mn}\end{bmatrix}$$

is called a *matrix*. The elements $a_{ij}$ may be real or complex. The notation $a_{ij}$ means the element in the $i$th row and $j$th column; $i$ is called the *row index* and $j$ the *column index*. If $m=n$, the matrix is said to be *square* and of order $n$. A matrix, even if it is square, does not have a numerical value, as a determinant does. However, if the matrix $A$ is square, a determinant can be formed which has the same elements as matrix $A$. This is called the *determinant* of the matrix and is written det $(A)$ or $|A|$. If $A$ is square and det $(A)\ne0$, then $A$ is said to be *nonsingular*; if det $(A)=0$, then $A$ is said to be *singular*. A matrix $A$ has rank $r$ if and only if it has a nonvanishing determinant of order $r$ and no nonvanishing determinant of order $>r$.

***Equality of Matrices*** Let $A=(a_{ij})$, $B=(b_{ij})$. Two matrices $A$ and $B$ are *equal* (=) if and only if they are identical; that is, they have the same number of rows and the same number of columns and equal corresponding elements ($a_{ij}=b_{ij}$ for all $i$ and $j$).

***Addition and Subtraction*** The operations of addition (+) and subtraction (−) of two or more matrices are possible if and only if the matrices have the same number of rows and columns. Thus $A\pm B=(a_{ij}\pm b_{ij})$; i.e., addition and subtraction are of corresponding elements.

***Transposition*** The matrix obtained from $A$ by interchanging the rows and columns of $A$ is called the *transpose* of $A$, written $A'$ or $A^T$.

***Example*** $A=\begin{bmatrix}1 & 3 & 4\\ 2 & 1 & 6\end{bmatrix}\quad A^T=\begin{bmatrix}1 & 2\\ 3 & 1\\ 4 & 6\end{bmatrix}$

Note that $(A^T)^T=A$.

***Multiplication*** Let $A = (a_{ij})$, $i = 1, \ldots, m_1$; $j = 1, \ldots, m_2$, and $B = (b_{ij})$, $i = 1, \ldots, n_1$, $j = 1, \ldots, n_2$. The product $AB$ is defined if and only if the number of columns of $A$ ($m_2$) equals the number of rows of $B$ ($n_1$), that is, $n_1 = m_2$. For two such matrices the product $P = AB$ is defined by summing the element-by-element products of a row of $A$ by a column of $B$.

This is the row-by-column rule. Thus

$$P_{ij} = \sum_{k=1}^{n_1} a_{ik} b_{kj}$$

The resulting matrix has $m_1$ rows and $n_2$ columns.

***Example*** $$\begin{bmatrix} 3 & 2 \\ 1 & 1 \\ 5 & 4 \end{bmatrix} \begin{bmatrix} 0 & 1 & 5 & 6 \\ -2 & 0 & 1 & 3 \end{bmatrix} = \begin{bmatrix} -4 & 3 & 17 & 24 \\ -2 & 1 & 6 & 9 \\ -8 & 5 & 29 & 42 \end{bmatrix}$$

It is helpful to remember that the element $P_{ij}$ is formed from the $i$th row of the first matrix and the $j$th column of the second matrix. The matrix product is not commutative. That is, $AB \neq BA$ in general.

***Inverse of a Matrix*** A square matrix $A$ is said to have an inverse if there exists a matrix $B$ such that $AB = BA = I$, where $I$ is the identity matrix of order $n$.

$$\begin{bmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 & \cdot\cdot & \\ \vdots & & 1 & 0 \\ 0 & \cdots & 0 & 1 \end{bmatrix}$$

The inverse $B$ is a square matrix of the order of $A$, designated by $A^{-1}$. Thus $AA^{-1} = A^{-1}A = I$. A square matrix $A$ has an inverse if and only if $A$ is nonsingular.

Certain relations are important:

(1) $(AB)^{-1} = B^{-1}A^{-1}$
(2) $(AB)^T = B^T A^T$
(3) $(A^{-1})^T = (A^T)^{-1}$
(4) $(ABC)^{-1} = C^{-1}B^{-1}A^{-1}$

***Scalar Multiplication*** Let $c$ be any real or complex number. Then $cA = (ca_{ij})$.

***Linear Equations in Matrix Form*** Every set of $n$ nonhomogeneous linear equations in $n$ unknowns

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n &= b_2 \\ \vdots & \quad \vdots \\ a_{n1}x_1 + a_{n2}x_2 + \cdots + a_{nn}x_n &= b_n \end{aligned}$$

can be written in matrix form as $AX = B$, where $A = (a_{ij})$, $X^T = [x_1 \cdots x_n]$, and $B^T = [b_1 \cdots b_n]$. The solution for the unknowns is $X = A^{-1}B$.

***Special Square Matrices***

1. A *triangular matrix* is a matrix all of whose elements above or below the main diagonal (set of elements $a_{11}, \ldots, a_{nn}$) are zero.

If $A$ is triangular, $\det(A) = a_{11}a_{22}\cdots a_{nn}$.

2. A *diagonal matrix* is one such that all elements both above and below the main diagonal are zero (that is, $a_{ij} = 0$ for all $i \neq j$). If all diagonal elements are equal, the matrix is called *scalar*. If $A$ is diagonal, $A = (a_{ij})$, $A^{-1} = (1/a_{ij})$.
3. If $a_{ij} = a_{ji}$ for all $i$ and $j$ (that is, $A = A^T$), the matrix is *symmetric*.
4. If $a_{ij} = -a_{ji}$ for $i \neq j$ but not all the $a_{ij}$ are zero, the matrix is *skew*.
5. If $a_{ij} = -a_{ji}$ for all $i$ and $j$ (that is, $a_{ii} = 0$), the matrix is *skew symmetric*.
6. If $A^T = A^{-1}$, the matrix $A$ is *orthogonal*.
7. If the matrix $A^* = (\bar{a}_{ij})^T$ and $\bar{a}_{ij}$ = complex conjugate of $a_{ij}$, then $A^*$ is the *hermitian transpose* of $A$.
8. If $A = A^{-1}$, then $A$ is *involutory*.
9. If $A = A^*$, then $A$ is *hermitian*.
10. If $A = -A^*$, then $A$ is *skew hermitian*.
11. If $A^{-1} = A^*$, then $A$ is *unitary*.

If $A$ is any matrix, then $AA^T$ and $A^TA$ are square symmetric matrices, usually of different order.

By using a program such as MATLAB, these are easily calculated.

**Matrix Calculus**

***Differentiation*** Let the elements of $A = [a_{ij}(t)]$ be differentiable functions of $t$. Then $\dfrac{dA}{dt} = \left[\dfrac{da_{ij}(t)}{dt}\right]$.

***Example*** $$A = \begin{bmatrix} \sin t & \cos t \\ -\cos t & \sin t \end{bmatrix} \quad \frac{dA}{dt} = \begin{bmatrix} \cos t & -\sin t \\ \sin t & \cos t \end{bmatrix}$$

***Integration*** The integral $\int A\,dt = [\int a_{ij}(t)\,dt]$.

***Example*** $$A = \begin{bmatrix} t & 2 \\ t^2 & e^t \end{bmatrix} \quad \int A\,dt = \begin{bmatrix} t^2/2 & 2t \\ t^3/3 & e^t \end{bmatrix}.$$

The matrix $B = A - \lambda I$ is called the *characteristic matrix* or *eigenmatrix* of $A$. Here $A$ is square of order $n$, $\lambda$ is a scalar parameter, and $I$ is the $n \times n$ identity matrix. So $\det B = \det(A - \lambda I) = 0$ is the characteristic equation (or eigenequation) for $A$. The characteristic equation is always of the same degree as the order of $A$. The roots of the characteristic equation are called the *eigenvalues* of $A$ or *characteristic values* of $A$.

***Example*** $$A = \begin{bmatrix} 1 & 2 \\ 3 & 8 \end{bmatrix} \quad B = \begin{bmatrix} 1 & 2 \\ 3 & 8 \end{bmatrix} - \begin{bmatrix} \lambda & 0 \\ 0 & \lambda \end{bmatrix} = \begin{bmatrix} 1-\lambda & 2 \\ 3 & 8-\lambda \end{bmatrix}.$$

Above is the characteristic matrix and $f(\lambda) = \det(B) = \det(A - \lambda I) = (1 - \lambda)(8 - \lambda) - 6 = 2 - 9\lambda + \lambda^2 = 0$ is the characteristic equation. The eigenvalues of $A$ are the roots of $\lambda^2 - 9\lambda + 2 = 0$, which are $(9 \pm \sqrt{73})/2$.

A nonzero matrix $X_i$, which has one column and $n$ rows, a column vector, satisfying the equation

$$(A - \lambda I)X_i = 0$$

and associated with the $i$th characteristic root $\lambda_i$ is called an *eigenvector*.

**Vector and Matrix Norms** To carry out error analysis for approximate and iterative methods for the solutions of linear systems, one needs notions for vectors in $R^n$ and for matrices that are analogous to the notion of length of a geometric vector. Let $R^n$ denote the set of all vectors with $n$ components, $x = (x_1, \ldots, x_n)$. In dealing with matrices it is convenient to treat vectors in $R^n$ as columns, and so $x = (x_1, \ldots, x_n)^T$; however, here we shall write them simply as row vectors. A *norm* on $R^n$ is a real-valued function $f$ defined on $R^n$ with the following properties:

1. $f(x) \geq 0$ for all $x \in R^n$.
2. $f(x) = 0$ if and only if $x = (0, 0, \ldots, 0)$.
3. $f(ax) = |a| f(x)$ for all real numbers $a$ and $x \in R^n$.
4. $f(x + y) \leqq f(x) + f(y)$ for all $x, y \in R^n$.

The usual notation for a norm is $f(x) = ||x||$.

The norm of a matrix is $\kappa(A) \equiv ||A||\,||A^{-1}||$

where $$||A|| \sup_{x \neq 0} = \frac{||Ax||}{||x||} = \max_k \sum_{j=1}^{n} |a_{jk}|$$

The norm is useful when doing numerical calculations. If the computer's floating-point precision is $10^{-6}$, then $\kappa = 10^6$ indicates an ill-conditioned matrix. If the floating-point precision is $10^{-12}$ (double precision), then a matrix with $\kappa = 10^{12}$ may be ill-conditioned. Two other measures are useful and are more easily calculated:

$$\text{Ratio} = \frac{\max_k |a_{kk}^{(k)}|}{\min_k |a_{kk}^{(k)}|} \qquad V = \frac{|\det A|}{\alpha_1 \alpha_2 \cdots \alpha_n} \qquad \alpha_1 = (\alpha_{i1}^2 + \alpha_{i2}^2 + \cdots + \alpha_{in}^2)^{1/2}$$

where $a_{kk}^{(k)}$ are the diagonal elements of the $LU$ decomposition.

## MATRIX COMPUTATIONS

The principal topics in linear algebra involve systems of linear equations, matrices, vector spaces, linear transformations, eigenvalues and eigenvectors, and least-squares problems. The calculations are routinely done on a computer.

***LU* Factorization of a Matrix** Let $L$ be an $n \times n$ lower triangular matrix with unit diagonal elements. Let $U$ be an $n \times n$ upper triangular matrix. If all the principal submatrices of an $n \times n$ matrix $A$ are nonsingular, then it is possible to represent $A = LU$. The Gauss elimination method is in essence an algorithm to determine $L$ and $U$.

**Solution of $Ax = b$ by Using *LU* Factorization** Suppose that the indicated system is compatible and that $A = LU$. Let $z = Ux$. Then $Ax = LUx = b$ implies that $Lz = b$. Thus to solve $Ax = b$ we first solve $Lz = b$ for $z$ and then solve $Ux = z$ for $x$. This procedure does not require that $A$ be invertible and can be used to determine all solutions of a compatible system $Ax = b$. Note that the systems $Lz = b$ and $Ux = z$ are both in triangular form and thus can be easily solved.

The $LU$ decomposition is essentially a gaussian elimination, arranged for maximum efficiency. The chief reason for doing an $LU$ decomposition is that it takes fewer multiplications than would be needed to find an inverse. Also, once the $LU$ decomposition has been found, it is possible to solve for

multiple right-hand sides with little increase in work. The multiplication count for an $n \times n$ matrix and $m$ right-hand sides is

$$\text{Operation count} = \frac{1}{3}n^3 - \frac{1}{3}n + mn^2$$

If an inverse is desired, it can be calculated by solving for the *LU* decomposition and then solving $n$ problems with right-hand sides consisting of all zeros except one entry. Thus $4n^2/3 - n/3$ multiplications are required for the inverse. The determinant is given by

$$\text{Det } A = \prod_{i=1}^{n} a_{ii}^{(i)}$$

where $a_{ii}^{(i)}$ are the diagonal elements obtained in the *LU* decomposition.

A *tridiagonal matrix* is one in which the only nonzero entries lie on the main diagonal and on the diagonal just above and just below the main diagonal. The set of equations can be written as

$$a_i x_{i-1} + b_i x_i + c_i x_{i+1} = d_i$$

The *LU* decomposition is

$$b_1 = b_1$$
for $k = 2, n$ do
$$a'_k = \frac{a_k}{b'_{k-1}}, \quad b'_k = b_k - \frac{a_k}{b'_{k-1}} c_{k-1}$$
enddo
$$d'_1 = d_1$$
for $k = 2, n$ do
$$d'_k = d_k - a'_k d'_{k-1}$$
enddo
$$x_n = d'_n / b'_n$$
for $k = n - 1, 1$ do
$$x_k = \frac{d'_k - c_k x_{k+1}}{d'_k}$$
enddo

The operation count for an $n \times n$ matrix with $m$ right-hand sides is

$$2(n-1) + m(3n-2)$$

If $|b_i| > |a_i| + |c_i|$, no pivoting is necessary, and this is true for many boundary-value problems and partial differential equations.

*Sparse* matrices are ones in which the majority of the elements are zero. If the structure of the matrix is exploited, the solution time on a computer is greatly reduced. See Duff, I. S., A. M. Erisman, and J. K. Reid, *Direct Methods for Sparse Matrices*, Clarendon Press, Oxford, UK, 1986; Davis, T. A., *Direct Methods for Sparse Linear Systems*, Society for Industrial and Applied Mathematics, Philadelphia, Penn., 2006. The conjugate gradient method is one method for solving sparse matrix problems, since it only involves multiplication of a matrix times a vector. Thus the sparseness of the matrix is easy to exploit. The conjugate gradient method is an iterative method that converges for sure in $n$ iterations where the matrix is an $n \times n$ matrix.

Matrix methods, in particular finding the rank of the matrix, can be used to find the number of independent reactions in a reaction set. If the stoichiometric numbers for the reactions and molecules are put in the form of a matrix, the rank of the matrix gives the number of independent reactions. See Amundson, N. R., *Mathematical Methods in Chemical Engineering*, Prentice-Hall, Englewood Cliffs, N.J., 1966, p. 50. See also Dimensional Analysis.

**QR Factorization of a Matrix** If $A$ is an $m \times n$ matrix with $m \geq n$, there exists an $m \times m$ unitary matrix $Q = [q_1, q_2, ..., q_m]$ and an $m \times n$ right triangular matrix $R$ such that $A = QR$. The $QR$ factorization is frequently used in the actual computations when the other transformations are unstable.

**Singular-Value Decomposition** If $A$ is an $m \times n$ matrix with $m \geq n$ and rank $k \leq n$, consider the two following matrices.

$$AA^* \qquad \text{and} \qquad A^*A$$

An $m \times m$ unitary matrix $U$ is formed from the eigenvectors $\mathbf{u}_i$ of the first matrix.

$$U = [\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_m]$$

An $n \times n$ unitary matrix $V$ is formed from the eigenvectors $\mathbf{v}_i$ of the second matrix.

$$V = [\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n]$$

Then matrix $A$ can be decomposed into

$$A = U \sum V^*$$

where $\sum$ is a $k \times k$ diagonal matrix with diagonal elements $d_{ii} = \sigma_i > 0$ for $1 \leq i \leq k$. The eigenvalues of $\sum^* \sum$ are $\sigma_i^2$. The vectors $\mathbf{u}_i$ for $k+1 \leq i \leq m$ and $\mathbf{v}_i$ for $k+1 \leq i \leq n$ are eigenvectors associated with the eigenvalue zero; the eigenvalues for $1 \leq i \leq k$ are $\sigma_i^2$. The values of $\sigma_i$ are called the *singular values* of matrix $A$. If $A$ is real, then $U$ and $V$ are real and hence orthogonal matrices. The value of the singular-value decomposition comes when a process is represented by a linear transformation and the elements of $A$ and $a_{ij}$ are the contribution to an output $i$ for a particular variable as input variable $j$. The input may be the size of a disturbance, and the output is the gain (Seborg, D. E., T. F. Edgar, and D. A. Mellichamp, *Process Dynamics and Control*, 2d ed., Wiley, New York, 2004). If the rank is less than $n$, not all the variables are independent and they cannot all be controlled. Furthermore, if the singular values are widely separated, the process is sensitive to small changes in the elements of the matrix, and the process will be difficult to control.

***Example*** Consider the following example from Noble and Daniel (*Applied Linear Algebra*, Prentice-Hall, Upper Saddle River, N.J., 1987) with the MATLAB commands to do the analysis. Define the following real matrix with $m = 3$ and $n = 2$ (whose rank $k = 1$).

```
>> a = [1  1
        2  2
        2  2]
```

The following MATLAB commands are used.

```
a1 = a*a
a2 = a*a'
[v, d1] = eig(a1)
[u, d2] = eig(a2)
```

The results are

```
v = [-0.7071   0.7071
      0.7071   0.7071]
d1 = [0   0
      0  18]

u = [ 0.8944   0.2981   0.3333
     -0.4472   0.5963   0.6667
      0       -0.7454   0.6667]

d2 = 0   0   0
     0   0   0
     0   0  18
```

Thus, $\sigma_1^2 = 18$ and the eigenfunctions are the rows of $\mathbf{v}$ and $\mathbf{u}$. The second column of $\mathbf{v}$ is associated with the eigenvalue $\sigma_1^2 = 18$, and the third column of $\mathbf{u}$ is associated with the eigenvalue $\sigma_1^2 = 18$.

If $A$ is square and nonsingular, the vector $\mathbf{x}$ that minimizes

$$||A\mathbf{x} - \mathbf{b}|| \tag{3-62}$$

is obtained by solving the linear equation

$$\mathbf{x} = A^{-1}\mathbf{b}$$

When $A$ is not square, the solution to

$$A\mathbf{x} = \mathbf{b}$$

is

$$\mathbf{x} = V\mathbf{y}$$

where $y_i = b_i'/\sigma_i$ for $i = 1, \ldots, k$, $\mathbf{b}' = U^T\mathbf{b}$, and $y_{k+1}, y_{k+2}, \ldots, y_m$ are arbitrary. The matrices $U$ and $V$ are those obtained in the singular-value decomposition. The solution which minimizes the norm, Eq. (3-62), is $\mathbf{x}$ with $y_{k+1}, y_{k+2}, \ldots, y_m$ zero. These techniques can be used to monitor process variables. See Montgomery, D. C., *Introduction to Statistical Quality Control*, 6th ed., Wiley, New York, 2008; Piovos, M. J., and K. A. Hoo, "Multivariate Statistics for Process Control," *IEEE Control Systems* **22**(5):8 (2002).

**Principal Component Analysis (PCA)** PCA is used to recognize patterns in data and reduce the dimensionality of the problem. Let the matrix $A$ now represent data with the columns of $A$ representing different samples and the rows representing different variables. The *covariance matrix* is defined as

$$\text{cov}(A) = \frac{A^T A}{m-1}$$

This is just the same matrix discussed with singular-value decomposition. For data analysis, however, it is necessary to adjust the columns to have zero mean by subtracting from each entry in the column the average of the column entries. Once this is done, the *loadings* are the $\mathbf{v}_i$ and satisfy

$$\text{cov}(A)\,\mathbf{v}_i = \sigma_i^2 \nu_i$$

and the *score* vector $\mathbf{u}_i$ is given by

$$A\mathbf{v}_i = \sigma_i \mathbf{u}_i$$

In process analysis, the columns of $A$ represent different measurement techniques (temperatures, pressures, etc.), and the rows represent the measurement output at different times. In that case the columns of $A$ are adjusted to have a zero mean and a variance of 1.0 (by dividing each entry in the column by the variance of the column). The goal is to represent the essential variation of the process with as few variables as possible. The $\mathbf{u}_i$, $\mathbf{v}_i$ pairs are arranged in descending order according to the associated $\sigma_i$. The $\sigma_i$ can be thought of as the variance, and the $\mathbf{u}_i$, $\mathbf{v}_i$ pair captures the greatest amount of variation in the data. Instead of having to deal with $n$ variables, one can capture most of the variation of the data by using only the first few pairs. An excellent example of this is given by Wise, B. M., and B. R. Kowalski, "Process Chemometrics," Chap. 8 in *Process Analytical Chemistry*, eds. F. McLennan and B. Kowalski, Blackie Academic & Professional, London, 1995. When modeling a slurry-fed ceramic melter, they were able to capture 97 percent of the variation by using only four eigenvalues and eigenvectors, even though there were 16 variables (columns) measured.

# NUMERICAL APPROXIMATIONS TO SOME EXPRESSIONS

## APPROXIMATION IDENTITIES

For the following relationships the sign ≅ means approximately equal to, when $X$ is small. These equations are derived by using a Taylor's series (see Series Summation and Identities).

| Approximation | Approximation |
|---|---|
| $\dfrac{1}{1 \pm X} \cong 1 \mp X$ | $\sqrt{1 \pm X} \cong 1 \pm \dfrac{X}{2}$ |
| $(1 \pm X)^n \cong 1 \pm nX$ | $(1 \pm X)^{-n} \cong 1 \mp nX$ |
| $(a \pm X)^2 = a^2 \pm 2aX$ | $e^x \cong 1 + X$ |
| $\sin X \cong X (X \text{ rad})$ | $\tan X \cong X$ |
| $\sqrt{Y(Y+X)} \cong \dfrac{2Y+X}{2}$ | $\sqrt{Y^2+X^2} \cong Y + \dfrac{X^2}{2Y}\left(\dfrac{X}{Y} \text{ small}\right)$ |
| Stirling's approximation | $\ln N! \cong N \ln N - N$ |

## INTRODUCTION

The goal of approximate and numerical methods is to provide convenient techniques for obtaining useful information from mathematical formulations of physical problems. Often this mathematical statement is not solvable by analytical means. Or perhaps analytic solutions are available but in a form that is inconvenient for direct interpretation. In the first case, it is necessary either to attempt to approximate the problem satisfactorily by one that will be amenable to analysis, to obtain an approximate solution to the original problem by numerical means, or to use the two techniques in combination. Numerical methods have been used to model polymerization, yeast fermentation, chemical vapor deposition, catalytic converters, pressure swing adsorption, insulin purification, ion exchange, and affinity chromatography, plus many other chemical engineering applications.

Numerical techniques therefore do not yield exact results in the sense of the mathematician. Since most numerical calculations are inexact, the concept of error is an important feature.

The four sources of error are as follows:

1. *Gross errors.* These result from unpredictable human, mechanical, or electrical mistakes.

2. *Rounding errors.* These are the consequence of using a number specified by $m$ correct digits to approximate a number which requires more than $m$ digits for its exact specification. For example, approximate the irrational number $\sqrt{2}$ by 1.414. Such errors are often present in experimental data, in which case they may be called *inherent errors*, due either to empiricism or to the fact that the computer dictates the number of digits. Such errors may be especially damaging in areas such as matrix inversion or the numerical solution of partial differential equations when the number of algebraic operations is extremely large.

3. *Truncation errors.* These errors arise from the substitution of a finite number of steps for an infinite sequence of steps which would yield the exact result. To illustrate this error, consider the infinite series for $e^{-x}$: $e^{-x} = 1 - x + x^2/2 - x^3/6 + E_T(x)$, where $E_T$ is the truncation error, $E_T = (1/24)e^{-\varepsilon}x^4$, for $0 < \varepsilon < x$. If $x$ is positive, $\varepsilon$ is also positive. Hence $e^{-\varepsilon} < 1$. The approximation $e^{-x} \approx 1 - x + x^2/2 - x^3/6$ is in error by a positive amount smaller than $(1/24)x^4$.

A variety of general-purpose computer programs are available commercially. Mathematica (http://www.wolfram.com/), Maple (http://www.maplesoft.com/), and Mathcad (https://www.ptc.com/en/engineering-math-software/mathcad) and MATLAB (http://www.mathworks.com/

product/symbolic) all have the capability of doing symbolic manipulation so that algebraic solutions can be obtained. Different packages can solve some ordinary and partial differential equations analytically, solve nonlinear algebraic equations, make simple graphs and do linear algebra, and combine the symbolic manipulation with numerical techniques. In this section, examples are given for the use of MATLAB (http://www.mathworks.com/), a package of numerical analysis tools, some of which are accessed by simple commands and others of which are accessed by writing programs in C. Spreadsheets can also be used to solve certain problems, and these are described below too. A popular program used in chemical engineering education is Polymath (http://www.polymath-software.com/), which can numerically solve sets of linear or nonlinear equations, ordinary differential equations as initial-value problems, and perform data analysis and regression.

## NUMERICAL SOLUTION OF LINEAR EQUATIONS

See the section Matrix Algebra and Matrix Computation.

## NUMERICAL SOLUTION OF NONLINEAR EQUATIONS IN ONE VARIABLE

**Methods for Nonlinear Equations in One Variable**

***Successive Substitutions*** Let $f(x) = 0$ be the nonlinear equation to be solved. If this is rewritten as $x = F(x)$, then an iterative scheme can be set up in the form $x_{k+1} = F(x_k)$. To start the iteration, an initial guess must be obtained graphically or otherwise. The convergence or divergence of the procedure depends upon the method of writing $x = F(x)$, of which there will usually be several forms. However, if $a$ is a root of $f(x) = 0$, and if $|F'(a)| < 1$, then for any initial approximation sufficiently close to $a$, the method converges to $a$. This process is called *first-order* because the error in $x_{k+1}$ is proportional to the first power of the error in $x_k$ for large $k$.

One way of writing the equation is $x_{k+1} = x_k + \beta f(x_k)$. The choice of $\beta$ is made such that $|1 + \beta\, df/dx(a)| < 1$. Convergence is guaranteed by the theorem given for simultaneous equations.

***Methods of Perturbation*** Let $f(x) = 0$ be the equation. In general, the iterative relation is

$$x_{k+1} = x_k - [f(x_k)/\alpha_k]$$

where the iteration begins with $x_0$ as an initial approximation and $\alpha_k$ as some functional, derived below.

***Newton-Raphson Procedure*** This variant chooses $\alpha_k = f'(x_k)$ where $f' = df/dx$ and geometrically consists of replacing the graph of $f(x)$ by the tangent line at $x = x_k$ in each successive step. If $f'(x)$ and $f''(x)$ have the same sign throughout an interval $a \le x \le b$ containing the solution, with $f(a)$ and $f(b)$ of opposite signs, then the process converges starting from any $x_0$ in the interval $a \le x \le b$. The process is second-order.

***Method of False Position*** This variant is commenced by finding $x_0$ and $x_1$ such that $f(x_0)$ and $f(x_1)$ are of opposite sign. Then $\alpha_1$ = slope of secant line joining $[x_0, f(x_0)]$ and $[x_1, f(x_1)]$ so that

$$x_2 = x_1 - \frac{x_1 - x_0}{f(x_1) - f(x_0)} f(x_1)$$

In each of the following steps $\alpha_k$ is the slope of the line joining $[x_k, f(x_k)]$ to the most recently determined point where $f(x_j)$ has the opposite sign from that of $f(x_k)$. This method is first-order. If one uses the most recently determined point (regardless of sign), the method is a *secant method.*

***Method of Wegstein*** This is a variant of the method of successive substitutions which forces and/or accelerates convergence. The iterative procedure $x_{k+1} = F(x_k)$ is revised by setting $\hat{x}_{k+1} = F(x_k)$ and then taking $x_{k+1} = qx_k + (1-q)\hat{x}_{k+1}$, where $q$ is a suitably chosen number which may be taken as constant throughout or may be adjusted at each step. Wegstein found that suitable $q$'s are as follows:

| Behavior of successive substitution process | | Range of optimum $q$ |
|---|---|---|
| Oscillatory convergence | | $0 < q < ½$ |
| Oscillatory divergence | without Wegstein | $½ < q < 1$ |
| Monotonic convergence | | $q < 0$ |
| Monotonic divergence | without Wegstein | $1 < q$ |

At each step $q$ may be calculated to give a locally optimum value by setting

$$q = \frac{\hat{x}_{k+1} - \hat{x}_k}{\hat{x}_{k+1} - 2\hat{x}_k + \hat{x}_{k-1}}$$

The Wegstein method is a secant method applied to $g(x) \equiv x - F(x)$. In Microsoft Excel, roots are found by using Goal Seek or Solver (an Add-In). Assign one cell to be $x$, put the equation for $f(x)$ in another cell, and let Goal Seek or Solver find the value of $x$ that makes the equation cell zero. In MATLAB, the process is similar except that a function (m–file) is defined and the command fzero ('$f$', x0) provides the solution $x$, starting from the initial guess $x0$. The Wegstein method is sometimes used to promote convergence when solving a mass and energy balance problem for a chemical process with recycle streams.

## METHODS FOR MULTIPLE NONLINEAR EQUATIONS

**Method of Successive Substitutions** Write a system of equations as

$$\alpha_i = f_i(\boldsymbol{\alpha}) \qquad \text{or} \qquad \boldsymbol{\alpha} = \mathbf{f}(\boldsymbol{\alpha})$$

The following theorem guarantees convergence. Let $\boldsymbol{\alpha}$ be the solution to $\alpha_i = f_i(\boldsymbol{\alpha})$. Assume that given $h > 0$, there exists a number $0 < \mu < 1$ such that

$$\sum_{j=1}^{n} \left| \frac{\partial f_i}{\partial x_j} \right| \le \mu \qquad \text{for} \qquad |x_i - \alpha_i| < h, \quad i = 1, \ldots, n$$

$$x_i^{k+1} = f_i(x_i^k)$$

Then $x_i^k \to \alpha_i$

as $k$ increases [see Finlayson (1980)].

**Newton-Raphson Method** To solve the set of equations

$$F_i(x_1, x_2, \ldots, x_n) = 0 \qquad \text{or} \qquad F_i(\{x_j\}) = 0 \qquad \text{or} \qquad F_i(\mathbf{x}) = 0$$

one uses a truncated Taylor series to get

$$0 = F_i(\{x^k\}) + \sum_{j=1}^{n} \left. \frac{\partial F_i}{\partial x_j} \right|_{x^k} (x_j^{k+1} + x_j^k)$$

Thus one solves iteratively from one point to another.

$$\sum_{j=1}^{n} A_{ij}^k (x_j^{k+1} - x_j^k) = -F_i(\{x^k\})$$

where $$A_{ij}^k = \left. \frac{\partial F_i}{\partial x_j} \right|_{x^k}$$

This method requires solution of sets of linear equations until either the functions are zero to some tolerance or the changes of the solution between iterations are small enough. Convergence is guaranteed provided the norm of matrix $\mathbf{A}$ is bounded, $\mathbf{F}(\mathbf{x})$ is bounded for the initial guess, and the second derivative of $\mathbf{F}(\mathbf{x})$ with respect to all variables is bounded. See Finlayson (1980) in General References. Homotopy methods are also possible; see Finlayson et al. (2006) in General References.

## INTERPOLATION

When a function is known at several points, it is sometimes useful to have a means to interpolate and assign a value between those points. The interpolation can be a global approximation, i.e., a function defined using all the points, or piecewise approximation, i.e., a collection of functions, each defined over several different subsets of the points.

**Lagrange Interpolation Formulas** A global polynomial is defined over the entire region of space

$$P_m(x) = \sum_{j=0}^{m} c_j x^j$$

This polynomial is of degree $m$ (highest power is $x^m$) and order $m + 1$ ($m + 1$ parameters $\{c_j\}$). If we are given a set of $m + 1$ points

$$y_1 = f(x_1), y_2 = f(x_2), \ldots, y_{m+1} = f(x_{m+1})$$

then Lagrange's formula gives a polynomial of degree $m$ that goes through the $m+1$ points:

$$P_m(x)=\frac{(x-x_2)(x-x_3)\cdots(x-x_{m+1})}{(x_1-x_2)(x_1-x_3)\cdots(x_1-x_{m+1})}y_1 + \frac{(x-x_1)(x-x_3)\cdots(x-x_{m+1})}{(x_2-x_1)(x_2-x_3)\cdots(x_2-x_{m+1})}y_2+\cdots + \frac{(x-x_1)(x-x_2)\cdots(x-x_{m+1})}{(x_{m+1}-x_1)(x_{m+1}-x_2)\cdots(x_{m+1}-x_m)}y_{m+1}$$

Note that each coefficient of $y_j$ is a polynomial of degree $m$ that vanishes at the points $\{x_j\}$ (except for one value of $j$) and takes the value of 1.0 at that point:

$$P_m(x_j)=y_j \qquad j=1,2,\ldots,m+1$$

If the function $f(x)$ is known, the error in the approximation is [www.netliborg/lapack]

$$|\text{error}(x)|\le\frac{|x_{m+1}-x_1|^{m+1}}{(n+2)!}\max_{x_1\le x\le x_{m+1}}|f^{(n+2)}(x)|$$

The evaluation of $P_m(x)$ at a point other than at the defining points can be made with Neville's algorithm [Press et al. (2007) in General References].

**Orthogonal Polynomials** Another form of polynomials is obtained by defining them so that they are orthogonal. It is required that $P_m(x)$ be orthogonal to $P_k(x)$ for $k=0,\ldots,m-1$.

$$\int_a^b W(x)P_k(x)P_m(x)dx=0 \qquad k=0,1,\ldots,m-1$$

The orthogonality includes a nonnegative weight function $W(x)\ge 0$ for all $a\le x\le b$. This procedure specifies the set of polynomials to within multiplicative constants, which are set by requiring the leading coefficient to be 1.0 or by requiring the norm to be 1.0.

$$\int_a^b W(x)P_m^2(x)dx=1$$

The polynomial $P_m(x)$ has $m$ roots in the closed interval $a$ to $b$.

The polynomial

$$p(x)=c_0P_0(x)+c_1P_1(x)+\cdots c_mP(x)$$

minimizes

$$I=\int_a^b W(x)[f(x)-p(x)]^2dx$$

for a function $f(x)$ when

$$c_j=\int_a^b W(x)f(x)P_j(x)dx/W_j \qquad W_j=\int_a^b W(x)P_j^2(x)dx$$

Note that each $c_j$ is independent of $m$, the number of terms retained in the series. The minimum value of $I$ is

$$I_{\min}=\int_a^b W(x)f^2(x)dx-\sum_{j=0}^{n}W_jc_j^2$$

Such functions are useful for continuous data, i.e., when $f(x)$ is known for all $x$.

The types of orthogonal polynomials include Chebyshev ($a=-1$, $b=1$, $W(x)=1$, used in spectral methods), Legendre ($a=-1$, $b=1$, $W(x)=1/\sqrt{1-x^2}$), shifted Legendre ($a=0$, $b=1$, $W(x)=1$), used in the orthogonal collocation method), Jacobi, Hermite ($a=-\infty$, $b=\infty$, $W(x)=e^{-x^2}$), and Laguerre polynomials.

**Linear Interpolation** The simplest piecewise continuous interpolation is a straight line between the points. If a function $f(x)$ is approximately linear in a certain range, then the ratio

$$\frac{f(x_1)-f(x_0)}{x_1-x_0}=f[x_0,x_1]$$

is approximately independent of $x_0$ and $x_1$ in the range. The linear approximation to the function $f(x)$, $x_0<x<x_1$ then leads to the interpolation formula

$$f(x)\approx f(x_0)+(x-x_0)f[x_0-x_1] \approx f(x_0)+\frac{x-x_0}{x_1-x_0}[f(x_1)-f(x_0)] \approx\frac{1}{x_1-x_0}[(x_1-x)f(x_0)-(x_0-x)f(x_1)]$$

Higher-order interpolation is also possible.

**Equally Spaced Forward Differences** If the ordinates are *equally spaced*, that is, $x_j-x_{j-1}=\Delta x$ for all $j$, then the first differences are denoted by $\Delta f(x_0)=f(x_1)-f(x_0)$ or $\Delta y_0=y_1-y_0$, where $y=f(x)$. The differences of these first differences, called *second differences*, are denoted by $\Delta^2y_0$, $\Delta^2y_1$, …, $\Delta^2y_n$. Thus

$$\Delta^2y_0=\Delta y_1-\Delta y_0=y_2-y_1-y_1+y_0=y_2-2y_1+y_0$$

and in general

$$\Delta^jy_0=\sum_{n=0}^{j}(-1)^n\binom{j}{n}y_{j-n}$$

where $\binom{j}{n}=\frac{j!}{n!(j-n)!}=$ binomial coefficients

If the ordinates are equally spaced,

$$x_{n+1}-x_n=\Delta x$$
$$y_n=y(x_n)$$

then the first and second differences are denoted by

$$\Delta y_n=y_{n+1}-y_n$$
$$\Delta^2y_n=\Delta y_{n+1}-\Delta y_n=y_{n+2}-2y_{n+1}+y_n$$

A new variable is defined

$$\alpha=\frac{x_a-x_0}{\Delta x}$$

and the finite interpolation formula through the points $y_0, y_1, \ldots, y_n$ is written as follows:

$$y_\alpha=y_0+\alpha\Delta y_0+\frac{\alpha(\alpha-1)}{2!}\Delta^2y_0+\cdots+\frac{\alpha(\alpha+1)\cdots(\alpha-n+1)}{n!}\Delta^ny_0 \qquad (3\text{-}63)$$

Keeping only the first two terms gives a straight line through $(x_0, y_0)$ and $(x_1, y_1)$; keeping the first three terms gives a quadratic function of position going through those points plus $(x_2, y_2)$. The value $\alpha=0$ gives $x=x_0$; $\alpha=1$ gives $x=x_1$; and so on.

**Equally Spaced Backward Differences** *Backward differences* are defined by

$$\nabla y_n=y_n-y_{n-1}$$
$$\nabla^2y_n=\nabla y_n-\nabla y_{n-1}=y_n-2y_{n-1}+y_{n-2}$$

The interpolation polynomial of order $n$ through the points $y_0, y_{-1}, \ldots, y_{-n}$ is

$$y_\alpha=y_0+\alpha\nabla y_0+\frac{\alpha(\alpha+1)}{2!}\nabla^2y_0+\cdots+\frac{\alpha(\alpha+1)\cdots(\alpha+n-1)}{n!}\nabla^ny_0$$

The value of $\alpha=0$ gives $x=x_0$; $\alpha=-1$ gives $x=x_{-1}$, and so on. Alternatively, the interpolation polynomial of order $n$ through the points $y_1, y_0, y_{-1}, \ldots, y_{-n}$ is

$$y_\alpha=y_1+(\alpha-1)\nabla y_1+\frac{\alpha(\alpha-1)}{2!}\nabla^2y_1+\cdots+\frac{(\alpha-1)\alpha(\alpha+1)\cdots(\alpha+n-2)}{n!}\nabla^ny_1 \qquad (3\text{-}64)$$

Now $\alpha=1$ gives $x=x_1$; $\alpha=0$ gives $x=x_0$.

**Central Differences** The central difference denoted by

$$\delta f(x)=f\left(x+\frac{h}{2}\right)-f\left(x-\frac{h}{2}\right)$$
$$\delta^2f(x)=\delta f\left(x+\frac{h}{2}\right)-\delta f\left(x-\frac{h}{2}\right)=f(x+h)-2f(x)+f(x-h)$$
$$\delta^nf(x)=\delta^{n-1}f\left(x+\frac{h}{2}\right)-\delta^{n-1}f\left(x-\frac{h}{2}\right)$$

is useful for calculating at the interior points of tabulated data.

**Finite Element Method** In the finite element method (see Ordinary Differential Equations—Boundary Value Problems) the independent variable $x$ is divided into regions called *elements.* The simplest approximation is to use linear interpolation on each element, as described above. More useful is to use a quadratic interpolation between the two endpoints of the element and its midpoint. The points of an element are shown in Fig. 3-46.

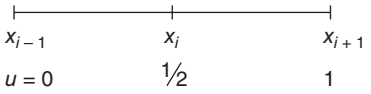

**FIG. 3-46** Quadratic finite element.

The element extends from $x_{i-1}$ to $x_{i+1}$. Define a new variable which takes the values $u = 0$, 0.5, and 1 at the three points, respectively. The interpolation is then

$$y = 2(u-1)\left(u-\frac{1}{2}\right)y_{i-1} + 4u(1-u)y_i + 2u\left(u-\frac{1}{2}\right)y_{i+1}$$

The interpolation clearly takes the correct values at $u = 0$, 0.5, and 1. Over the whole domain in $x$ the interpolated function is continuous, but the first derivative is only piecewise continuous. Other types of finite elements include cubic functions, which are also continuous but the derivatives are only piecewise continuous. When Hermite cubic functions are used, however, the function and its first derivative are continuous throughout the domain in $x$.

**Spline Functions** Splines are functions that match given values at the points $x_1, \ldots, x_{NT}$ and have continuous derivatives up to some order at the knots, or the points $x_2, \ldots, x_{NT-1}$. Cubic splines are most common. The function is represented by a cubic polynomial within each interval $(x_i, x_{i+1})$ and has continuous first and second derivatives at the knots. Two more conditions can be specified arbitrarily. These are usually the second derivatives at the two endpoints, which are commonly taken as zero; this gives the natural cubic splines. Spline functions are useful because the interpolation error can be made small even with low-order polynomials. Some of the other methods may oscillate wildly between the quadrature points. See Schumaker, L. L., *Spline Functions: Computational Methods*, Soc. Ind. Appl. Math. (SIAM), 2015.

## NUMERICAL DIFFERENTIATION

Numerical differentiation should be avoided whenever possible, particularly when data are empirical and subject to appreciable observation errors. Errors in data can affect numerical derivatives quite strongly; i.e., differentiation is a roughening process. When such a calculation must be made, it is usually desirable first to smooth the data to a certain extent.

**Use of Interpolation Formula** If the data are given over equidistant values of the independent variable $x$, an interpolation formula such as the Newton formula [Eq. (3-63) or (3-64)] may be used and the resulting formula differentiated analytically. If the independent variable is not at equidistant values, then Lagrange's formulas must be used. By differentiating three-point Lagrange interpolation formulas the following differentiation formulas result for equally spaced tabular points:

***Three-Point Formulas*** Let $x_0$, $x_1$, and $x_2$ be the three points.

$$f'(x_0) = \frac{1}{2h}[-3f(x_0) + 4f(x_1) - f(x_2)] + \frac{h^2}{3}f'''(\varepsilon)$$

$$f'(x_1) = \frac{1}{2h}[-f(x_0) + f(x_2)] - \frac{h^2}{6}f'''(\varepsilon)$$

$$f'(x_2) = \frac{1}{2h}[f(x_0) - 4f(x_1) + 3f(x_2)] + \frac{h^2}{3}f'''(\varepsilon)$$

where the last term is an error term $\min_j x_j < \varepsilon < \max_j x_j$.

**Smoothing Techniques** These techniques involve the approximation of the tabular data by a least-squares fit of the data by using some known functional form, usually a polynomial ( for the concept of least squares see Statistics). In place of approximating $f(x)$ by a single least-squares polynomial of degree $n$ over the entire range of the tabulation, it is often desirable to replace each tabulated value by the value taken on by a least-squares polynomial of degree $n$ relevant to a subrange of $2M + 1$ points centered, when possible, at the point for which the entry is to be modified. Thus each smoothed value replaces a tabulated value. Let $f_j = f(x_j)$ be the tabular points and $y_j$ = smoothed values.

***First-Degree Least Squares with Three Points***

$$y_0 = \tfrac{1}{6}[5f_0 + 2f_1 - f_2]$$
$$y_1 = \tfrac{1}{3}[f_0 + f_1 + f_2]$$
$$y_2 = \tfrac{1}{6}[-f_0 + 2f_1 + 5f_2]$$

The derivatives at all the points are

$$f_0' = f_1' = f_2' = \frac{1}{2}h[y_2 - y_1]$$

***Second-Degree Least Squares with Five Points*** For five evenly spaced points $x_{-2}$, $x_{-1}$, $x_0$, $x_1$, and $x_2$ (separated by distance $h$) and their ordinates $f_{-2}$, $f_{-1}$, $f_0$, $f_1$, and $f_2$, assume a parabola is fit by least squares. Then the derivative at the center point is

$$f_0' = 1/10h\,[-2f_{-2} - f_{-1} + f_1 + 2f_2]$$

The derivatives at the other points are

$$f_{-2}' = 1/70h[-54f_{-2} + 13f_{-1} + 40f_0 + 27f_1 - 26f_2]$$
$$f_{-1}' = 1/70h[-34f_{-2} + 3f_{-1} + 20f_0 + 17f_1 - 6f_2]$$
$$f_1' = 1/70h[6f_{-2} - 17f_{-1} + 20f_0 - 3f_1 + 34f_2]$$
$$f_2' = 1/70h[26f_{-2} - 27f_{-1} - 40f_0 - 13f_1 + 54f_2]$$

**Numerical Derivatives** The results given above can be used to obtain numerical derivatives when solving problems on the computer, in particular for the Newton-Raphson method and homotopy methods. Suppose one has a program, subroutine, or other function evaluation device that will calculate $f$, given $x$. One can estimate the value of the first derivative at $x_0$ using

$$\left.\frac{df}{dx}\right|_{x_0} \approx \frac{f[x_0(1+\varepsilon)] - f[x_0]}{\varepsilon\, x_0}$$

(a first-order formula) or

$$\left.\frac{df}{dx}\right|_{x_0} \approx \frac{f[x_0(1+\varepsilon)] - f[x_0(1-\varepsilon)]}{2\,\varepsilon\, x_0}$$

(a second-order formula). The value of ε is important; a value of $10^{-6}$ is typical, but smaller or larger values may be necessary depending on the computer precision and the application. One must also be sure that the value of $x_0$ is not zero and use a different increment in that case.

## NUMERICAL INTEGRATION (QUADRATURE)

A multitude of formulas have been developed to accomplish numerical integration, which consists of computing the value of a definite integral from a set of numerical values of the integrand.

**Newton-Cotes Integration Formulas (Equally Spaced Ordinates) for Functions of One Variable** The definite integral $\int_a^b f(x)\,dx$ is to be evaluated.

***Trapezoidal Rule*** This formula consists of subdividing the interval $a \le x \le b$ into $n$ subintervals $a$ to $a + h$, $a + h$ to $a + 2h$, … and replacing the graph of $f(x)$ by the result of joining the ends of adjacent ordinates by line segments. If $f_j = f(x_j) = f(a + jh)$, $f_0 = f(a)$, and $f_n = f(b)$, the integration formula is

$$\int_a^b f(x)\,dx = \frac{h}{2}[f_0 + 2f_1 + 2f_2 + \cdots + 2f_{n-1} + f_n] + E_n$$

where

$$|E_n| = \frac{nh^3}{12}|f''(\varepsilon)| = \frac{(b-a)^3}{12n^2}|f''(\varepsilon)| \qquad a < \varepsilon < b$$

This procedure is not of high accuracy. However, if $f'' \le (x)$ is continuous in $a < x < b$, the error goes to zero as $1/n^2$, $n \to \infty$. When the finite element method is used with linear trial functions and equal-size elements, quadrature is the same as the trapezoid rule.

***Parabolic Rule (Simpson's Rule)*** This procedure consists of subdividing the interval $a < x < b$ into $n/2$ subintervals, each of length $2h$, where $n$ is an *even* integer. By using the notation as above the integration formula is

$$\int_a^b f(x)\,dx = \frac{h}{3}[f_0 + 4f_1 + 2f_2 + 4f_3 + 2f_4 + \cdots + 4f_{n-3} + 2f_{n-2} + 4f_{n-1} + f_n] + E_n$$

where

$$|E_n| = \frac{nh^5}{180}|f^{(\mathrm{IV})}(\varepsilon)| = \frac{(b-a)^5}{180n^4}|f^{(\mathrm{IV})}(\varepsilon)| \qquad a < \varepsilon < b$$

This method approximates $f(x)$ by a parabola on each subinterval. This rule is generally more accurate than the trapezoidal rule. It is the most widely used integration formula. When the finite element method is used with quadratic trial functions and equal-size elements, quadrature is the same as Simpson's rule.

**Gaussian Quadrature** Gaussian quadrature provides a highly accurate formula based on irregularly spaced points, but the integral needs to be transformed onto the interval from 0 to 1.

$$x = a + (b-a)u \qquad dx = (b-a)du$$

$$\int_a^b f(x)\,dx = (b-a)\int_0^1 f(u)\,du$$

$$\int_a^b f(u)\,du = \sum_{i=1}^{m} W_i f(u_i)$$

The quadrature is exact when $f$ is a polynomial of degree $2m-1$ in $x$. Because there are $m$ weights and $m$ Gauss points, we have $2m$ parameters that are chosen to exactly represent a polynomial of degree $2m-1$, which has $2m$ parameters. The Gauss points and weights are given in the table.

**Gaussian Quadrature Points and Weights**

| $m$ | $u_i$ | $W_i$ |
|---|---|---|
| 2 | 0.21132 48654 | 0.50000 00000 |
| | 0.78867 51346 | 0.50000 00000 |
| 3 | 0.11270 16654 | 0.27777 77778 |
| | 0.50000 00000 | 0.44444 44445 |
| | 0.88729 83346 | 0.27777 77778 |
| 4 | 0.06943 18442 | 0.17392 74226 |
| | 0.33000 94783 | 0.32607 25774 |
| | 0.66999 05218 | 0.32607 25774 |
| | 0.93056 81558 | 0.17392 74226 |
| 5 | 0.04691 00771 | 0.11846 34425 |
| | 0.23076 53450 | 0.23931 43353 |
| | 0.50000 00000 | 0.28444 44444 |
| | 0.76923 46551 | 0.23931 43353 |
| | 0.95308 99230 | 0.11846 34425 |

***Example*** Calculate the value of the following integral.

$$I = \int_0^1 e^{-x} \sin x\, dx$$

Using the gaussian quadrature formulas gives the following values for various values of $m$. Clearly, three internal points, requiring evaluation of the integrand at only three points, give excellent results.

| $m$ | $I$ |
|---|---|
| 2 | 0.24609 64306 |
| 3 | 0.24583 48774 |
| 4 | 0.24583 70044 |
| 5 | 0.24583 70070 |

**Romberg's Method** Romberg's method uses extrapolation techniques to improve the answer [Press et al. (2007)]. If we let $I_1$ be the value of the integral obtained using interval size $h = \Delta x$, $I_2$ be the value of $I$ obtained when using interval size $h/2$, $I_3$ be the value obtained when using an interval of size $h/4$, etc., and $I_0$ is the true value of $I$, then the error in a method is approximately $h^m$, or

$$I \approx I_0 + ch^m$$

$$I_2 \approx I_0 + c\left(\frac{h}{2}\right)^m$$

Replacing the ≈ by an equality (an approximation) and solving for $c$ and $I_0$ give

$$I_0 = \frac{2^m I_2 - I_1}{2^m - 1}$$

To obtain the most accurate value, first calculate $I_1$, $I_2$, …, by halving $h$ each time. Then calculate new estimates from each pair, calling them $J_1$, $J_2$, … ; that is, in the formula above, replace $I_0$ with $J_1$. The formulas are reapplied for each pair of $J$ to obtain $K_1$, $K_2$, …. The process continues until the required tolerance is obtained.

$$\begin{array}{cccc} I_1 & I_2 & I_3 & I_4 \\ & J_1 & J_2 & J_3 \\ & & K_1 & K_2 \\ & & & L_1 \end{array}$$

Romberg's method is most useful for a low-order method (small $m$) because significant improvement is then possible.

***Example*** Evaluate the same integral by using the trapezoid rule and then apply the Romberg method. Use 11, 21, 41, and 81 points with $m = 2$. To achieve six-digit accuracy, any result from $J_2$ through $L_1$ is suitable, even though the base results ($I_1$ through $I_4$) are not that accurate.

| | | | |
|---|---|---|---|
| $I_1 = 0.24491\ 14823$ | $I_2 = 0.24560\ 56002$ | $I_3 = 0.24577\ 91537$ | $I_4 = 0.24582\ 25436$ |
| | $J_1 = 0.24583\ 69728$ | $J_2 = 0.24583\ 70049$ | $J_3 = 0.24583\ 70069$ |
| | | $K_1 = 0.24583\ 70156$ | $K_2 = 0.24583\ 70075$ |
| | | | $L_1 = 0.24583\ 70049$ |

**Orthogonal Polynomials** The quadrature formulas for orthogonal polynomials are the same as for gaussian quadrature above, with different points and different weights.

**Cubic Splines** The quadrature formula is

$$\int_{x_1}^{x_{NT}} y(x)\,dx = \frac{1}{2}\sum_{i=1}^{NT-1} \Delta x_i (y_i + y_{i+1}) - \frac{1}{24}\sum_{i=1}^{NT-1} \Delta x_i^3 (y_i'' + y_{i+1}'')$$

with $y_1' = 0$, $y_{NT}'' = 0$ for natural cubic splines.

*Computer Methods* These methods are easily programmed in a spreadsheet program such as Microsoft Excel. In MATLAB, the trapezoid rule can be calculated by using the command trapz(x,y), where x is a vector of $x$ values $x_i$ and y is a vector of values $y(x_i)$. Alternatively, use the commands

```
F = @(x) exp(-x).*sin(x)
Q = quad(F,0,1)
```

Monte Carlo methods can be used, too (see Monte Carlo Simulations).

**Singularities** When the integrand has singularities, a variety of techniques can be tried. The integral may be divided into one part that can be integrated analytically near the singularity and another part that is integrated numerically. Sometimes a change of argument allows analytical integration. Series expansion might be helpful, too. When the domain is infinite, it is possible to use Gauss-Legendre or Gauss-Hermite quadrature. Also a transformation can be made. For example, let $u = 1/x$ and then

$$\int_a^b f(x)\,dx = \int_{1/b}^{1/a} \frac{1}{u^2} f\left(\frac{1}{u}\right) du \qquad ab > 0$$

**Two-Dimensional Formula** Two-dimensional integrals can be calculated by breaking down the integral into one-dimensional integrals.

$$\int_a^b \int_{g_1(x)}^{g_2(x)} f(x,y)\,dx\,dy = \int_a^b G(x)\,dx$$

$$G(x) = \int_{g_1(x)}^{g_2(x)} f(x,y)\,dy$$

Gaussian quadrature can also be used in two dimensions, provided the integration is on a square or can be transformed to one. (Domain transformations might be used to convert the domain to a square.)

$$\int_0^1 \int_0^1 f(x,y)dx\,dy = \sum_{i=1}^{mx} W_{xi} \sum_{i=1}^{my} W_{yi} f(x_i, y_j)$$

# NUMERICAL SOLUTION OF ORDINARY DIFFERENTIAL EQUATIONS AS INITIAL-VALUE PROBLEMS

A differential equation for a function that depends on only one variable, often the variable time, is called an *ordinary differential equation*. The general solution to the differential equation includes many possibilities; the boundary or initial conditions are needed to specify which of those are desired. If all conditions are at one point, then the problem is an initial-value problem and can be integrated from that point on. If some of the conditions are available at one point and others at another point, then the ordinary differential equations become two-point boundary-value problems, which are treated in the next section. Initial-value problems as ordinary differential equations arise in control of lumped-parameter models, transient models of stirred tank reactors, and in all models where there are no spatial gradients in the unknowns. Many computer packages exist to solve initial-value problems, but it is important to understand the choices one must make and how to interpret the output (and change the choices) when the results are anomalous. Furthermore, many problems can be solved using spreadsheets (universally available) provided one understands the methods. It is important to know, too, when simple methods in spreadsheets won't work.

A higher-order differential equation

$$z^{(n)} + F(z^{(n-1)}, z^{(n-2)}, \ldots, z) = 0$$

with initial conditions for $z$, and its first $n-1$ derivatives can be converted into a set of first-order equations using

$$y_i \equiv z^{(i-1)} = \frac{d^{(i-1)}z}{dt^{(i-1)}} = \frac{d}{dt}\, z^{(i-2)} = \frac{dy_{i-1}}{dt}$$

The higher-order equation can be written as a set of first-order equations.

$$\frac{dy_1}{dt} = y_2, \frac{dy_2}{dt} = y_3, \frac{dy_3}{dt} = y_4, \ldots, \frac{dy_n}{dt} = -F(y_{n-1}, y_{n-2}, \ldots, y_2, y_1)$$

The set of equations is then written as

$$\frac{d\mathbf{y}}{dt} = \mathbf{f}(\mathbf{y}, t), \mathbf{y}(0) = \mathbf{y}_0$$

The methods in this section are described for a single equation, but they all apply to multiple equations.

The simplest method is Euler's method, which is first-order.

$$y^{n+1} = y^n + \Delta t\, f(y^n)$$

and errors are proportional to $\Delta t$. The second-order Adams-Bashforth method is

$$y^{n+1} = y^n + \frac{\Delta t}{2}[3f(y^n) - f(y^{n-1})]$$

Errors are proportional to $\Delta t^2$, and high-order methods are available. Notice that the higher-order explicit methods require knowing the solution (or the right-hand side) evaluated at times in the past. Since these were calculated to get to the current time, this presents no problem except for starting the problem. Then it may be necessary to use Euler's method with a very small step size for several steps in order to generate starting values at a succession of time points. The methods, error terms, order of the method, function evaluations per step, and stability limitations are listed in Finlayson (1980) in General References. The advantage of the high-order Adams-Bashforth method is that it uses only one function evaluation per step, yet achieves high-order accuracy. The disadvantage is the necessity of using another method to start. In MATLAB the function ode113 uses a version of the Adams-Bashforth method.

These methods can be used for simple problems when all the variables change on the same time scale and precise results are not needed. Euler's method is easily done in a spreadsheet. Figure 3-47 shows the commands in a spreadsheet for two differential equations, columns 1 to 3.

$$dy_1/dt = y_2 - y_1, \quad dy_2/dt = -y_2, \quad y_1(0) = 1, \quad y_2(0) = 1$$

Once columns 4 to 6 are created, the formulas for the additional time steps are created by copying down. The Richardson extrapolation (see below) can be used to improve the accuracy.

Runge-Kutta methods are explicit methods that use several function evaluations for each time step. Runge-Kutta methods are traditionally written

| Equations | Equations | Equations | | delta t | 0.1 |
|---|---|---|---|---|---|
| Eq. time | Eq. 1 | Eq. 2 | time | Results 1 | Results 2 |
| 0 | 1 | 1 | 0 | 1 | 1 |
| =D3+$F$1 | =E3+$F$1*(F3–E3) | =F3–$F$1*F3 | 0.1 | 1 | 0.9 |
| =D4+$F$1 | =E4+$F$1*(F4–E4) | =F4–$F$1*F4 | 0.2 | 0.99 | 0.81 |
| =D5+$F$1 | =E5+$F$1*(F5–E5) | =F5–$F$1*F5 | 0.3 | 0.972 | 0.729 |
| =D6+$F$1 | =E6+$F$1*(F6–E6) | =F6–$F$1*F6 | 0.4 | 0.9477 | 0.6561 |
| =D7+$F$1 | =E7+$F$1*(F7–E7) | =F7–$F$1*F7 | 0.5 | 0.91854 | 0.59049 |

**FIG. 3-47** Spreadsheet for Euler's method.

for $f(t, y)$. The first-order Runge-Kutta method is Euler's method. A second-order Runge-Kutta method is

$$y^{n+1} = y^n + \frac{\Delta t}{2}[f^n + f(t^n + \Delta t, y^n + \Delta t\, f^n)]$$

while the midpoint scheme is also a second-order Runge-Kutta method

$$y^{n+1} = y^n + \Delta t\, f\left(t^n + \frac{\Delta t}{2}, y^n + \frac{\Delta t}{2} f^n\right)$$

A popular fourth-order Runge-Kutta method uses the Runge-Kutta-Fehlberg formulas, which have the property that the method is fourth-order but achieves fifth-order accuracy. The coefficients are available at en.wikipedia.org/wiki/Runge-Kutta-Fehlberg_method. An extension of this method is ode45 in MATLAB.

Usually one would use a high-order method to achieve high accuracy. The Runge-Kutta-Fehlberg method is popular because it is high-order and does not require a starting method (as does an Adams-Bashforth method). However, it does require four function evaluations per time step, or four times as many as a fourth-order Adams-Bashforth method. For problems in which the function evaluations are a significant portion of the calculation time, this might be important. Given the speed and availability of desktop computers, the efficiency of the methods is most important only for very large problems that are going to be solved many times or for problems in which some variables change rapidly while others change slowly. For other problems, the most important criterion for choosing a method is probably the time the user spends setting up the problem.

The stability limits for the explicit methods are based on the largest eigenvalue of the linearized system of equations

$$\frac{dy_i}{dt} = \sum_{j=1}^{n} A_{ij}\, y_j, \; A_{ij} = \left.\frac{\delta f_i}{\delta y_j}\right|_y$$

For linear problems, the eigenvalues do not change, so that the stability and oscillation limits must be satisfied for *every* eigenvalue of matrix **A**. In solving nonlinear problems, the equations are linearized about the solution at the local time, and the analysis applies for small changes in time, after which a new analysis about the new solution must be made. Thus, for nonlinear problems, the eigenvalues keep changing, and the largest stable time step changes, too. The stability limits are as follows:

Euler method, $\lambda\, \Delta t \le 2$

Runge-Kutta, second-order, $\lambda\, \Delta t < 2$

Runge-Kutta-Fehlberg, $\lambda\, \Delta t < 3.0$

Richardson extrapolation can be used to improve the accuracy of a method. Suppose we step forward one step $\Delta t$ with a $p$th-order method. Then redo the problem, this time stepping forward from the same initial point, but in two steps of length $\Delta t/2$, thus ending at the same point. Call the solution of the one-step calculation $y_1$ and the solution of the two-step calculation $y_2$. Then an improved solution at the new time is given by

$$y = \frac{2^p y_2 - y_1}{2^p - 1}$$

This gives a good estimate provided $\Delta t$ is small enough that the method is truly convergent with order $p$. This process can also be repeated in the same way Romberg's method was used for quadrature.

The error term in the various methods can be used to deduce a step size that will give a user-specified accuracy. Most packages today are based on a user-specified tolerance; the step size is changed during the calculation to

achieve that accuracy. The accuracy itself is not guaranteed, but it improves as the tolerance is decreased.

**Implicit Methods** When some dependent variables change rapidly while others change slowly, we say the problem is *stiff* and implicit methods are needed. Implicit methods use different interpolation formulas involving $y^{n+1}$ and result in nonlinear equations to be solved for $y^{n+1}$. Then iterative methods must be used to solve the equations.

The backward Euler method is a first-order method:

$$y^{n+1} = y^n + \Delta t f(y^{n+1})$$

Errors are proportional to $\Delta t$ for small $\Delta t$. The trapezoid rule is a second-order method.

$$y^{n+1} = y^n + \frac{\Delta t}{2}[f(y^n) + f(y^{n+1})]$$

Errors are proportional to $\Delta t^2$ for small $\Delta t$. When the trapezoid rule is used with the finite difference method for solving partial differential equations, it is called the *Crank-Nicolson method*. The implicit methods are stable for any step size but do require the solution of a set of nonlinear equations, which must be solved iteratively. The set of equations can be solved using the successive substitution method or Newton-Raphson method. See Bogacki, M. B., K. Alejski, and J. Szymanewski, *Comp. Chem. Eng.* **13:** 1081–1085 (1989) for an application to dynamic distillation problems.

The best packages for stiff equations (see below) use backward-difference formulas. Gear first developed these, and the first two orders are given below (Gear, G. W., *Numerical Initial Value Problems in Ordinary Differential Equations*, Prentice-Hall, Englewood Cliffs, N.J., 1971).

1. $y^{n+1} = y^n + \Delta t f(y^{n+1})$
2. $y^{n+1} = \frac{4}{3}y^n + \frac{1}{3}y^{n-1} + \frac{2}{3}\Delta t\, f(y^{n+1})$

These methods require solving sets of nonlinear equations. By adroit manipulation and estimation, a package will change the order to achieve a required accuracy with a minimum number of time steps and iterations. The programs ode15s and ode23s in MATLAB use these techniques.

**Stiffness** The concept of stiffness is described for a system of linear equations.

$$\frac{d\mathbf{y}}{dt} = \mathbf{A}\mathbf{y}$$

Let $\lambda_i$ be the eigenvalues of matrix **A**. The *stiffness ratio* SR is defined as

$$\mathrm{SR} = \frac{\max_i |\mathrm{Re}(\lambda_i)|}{\max_i |\mathrm{Re}(\lambda_i)|} \tag{3-65}$$

SR = 20 is not stiff, SR = $10^3$ is stiff, and SR = $10^6$ is very stiff. If the problem is nonlinear, then the solution is expanded about the current state.

$$\frac{dy_i}{dt} = f_i[y(t^n)] + \sum_{j=1}^{n} \frac{\partial f_i}{\partial y_j}[y_j - y_j(t^n)]$$

The question of stiffness then depends on the solution at the current time. Consequently nonlinear problems can be stiff during one time period and not stiff during another. While the chemical engineer may not actually calculate the eigenvalues, it is useful to know that they determine the stability and accuracy of the numerical scheme and the step size used.

Problems are stiff when the time constants for different phenomena have very different magnitudes. Consider flow through a packed bed reactor. The time constants for different phenomena are as follows:

1. Time for device flow-through

$$t_{\text{flow}} = \frac{L}{u} = \frac{\phi AL}{Q}$$

where $Q$ is the volumetric flow rate, $A$ is the cross-sectional area, $L$ is the length of the packed bed, and $\phi$ is the void fraction.

2. Time for reaction

$$t_{r\times n} = \frac{1}{k}$$

where $k$ is a rate constant (time$^{-1}$).

3. Time for diffusion inside the catalyst

$$t_{\text{internal diffusion}} = \frac{\varepsilon R^2}{D_e}$$

where $\varepsilon$ is the porosity of the catalyst, $R$ is the catalyst radius, and $D_e$ is the effective diffusion coefficient inside the catalyst.

4. Time for heat transfer is

$$t_{\text{internal heat transfer}} = \frac{R^2}{\alpha} = \frac{\rho_s C_s R^2}{k_e}$$

where $\rho_s$ is the catalyst density, $C_s$ is the catalyst heat capacity per unit mass, $k_e$ is the effective thermal conductivity of the catalyst, and $\alpha$ is the thermal diffusivity. For example, in the model of a catalytic converter for an automobile [Ferguson, N. B., and B. A. Finlayson, *AIChE J.* **20:** 539–550 (1974)], the time constant for internal diffusion was 0.3 s; internal heat transfer, 21 s; and device flow-through, 0.003 s. The device flow-through is so fast that it might as well be instantaneous. The stiffness is approximately 7000, and implicit methods must be used to integrate the equations. Alternatively, a quasi-static model can be developed. In this case the time derivative is deleted for the variables that change rapidly on the grounds that those variables are essentially in steady state with respect to the rest of the problem, even if the steady state changes slowly.

**Differential-Algebraic Systems** Sometimes models involve ordinary differential equations subject to some algebraic constraints. For example, the equations governing one equilibrium stage (as in a distillation column) are

$$M\frac{dx^n}{dt} = V^{n+1}y^{n+1} - L^n x^n - V^n y^n + L^{n-1}x^{x-1}$$
$$x^{n-1} - x^n = E^n(x^{n-1} - x^{*n})$$
$$\sum_{i=1}^{N} x_i = 1$$

where $x$ and $y$ are the mole fraction in the liquid and vapor, respectively; $L$ and $V$ are liquid and vapor flow rates, respectively; $M$ is the holdup; and the superscript is the stage number. The efficiency is $E$, and the concentration in equilibrium with the vapor is $x^*$. The first equation is an ordinary differential equation for the mass of one component on the stage, while the third equation represents a constraint that the mass fractions add to 1. This is a *differential-algebraic* system of equations.

Differential-algebraic equations can be written in the general notation

$$F\left(t, y, \frac{dy}{dt}\right) = 0$$

To solve the general problem by using the backward Euler method, replace the nonlinear differential equation with the nonlinear algebraic equation for one step.

$$F\left(t, y^{n+1}, \frac{y^{n+1} - y^n}{\Delta t}\right) = 0$$

This equation must be solved for $y^{n+1}$. The Newton-Raphson method can be used, and if convergence is not achieved within a few iterations, the time step can be reduced and the step repeated. In actuality, the higher-order backward-difference Gear methods are used in DASSL (Ascher, U. M., and L. R. Petzold, *Computer Methods for Ordinary Differential Equations and Differential-Algebraic Equations*, SIAM, Philadelphia, Penn., 1998). The program ode15s in MATLAB can be used to solve differential-algebraic equations.

Differential-algebraic systems are more complicated than differential systems because the solution may not always be defined. See Pontelides et al. [*Comp. Chem. Eng.* **12:** 449–454 (1988)] for a model of a distillation column in which the column pressure strongly affects the possible solutions and initial conditions. Byrne and Ponzi [*Comp. Chem. Eng.* **12:** 377–382 (1988)] and Chan, T. F. C., and H. B. Keller [*SIAM J. Sci. Stat. Comput.* **3:** 173–194 (1982)] also list several chemical engineering examples of differential-algebraic systems and solve one involving two-phase flow.

**Computer Software** Efficient computer packages are available for solving ordinary differential equations as initial-value problems. The packages are widely available and good enough that most chemical engineers use them and do not write their own. On the NIST web page http://gams.nist.gov/Problem.html insert "ordinary differential equations" to find packages that can be downloaded. On the Netlib website http://www.netlib.org/, search the Netlib repository, and choose "ode" to find packages that can be downloaded. Using Microsoft Excel to solve ordinary differential equations is cumbersome, except for the simplest problems.

**Stability, Bifurcations, and Limit Cycles** Some aspects of this subject involve the solution of nonlinear equations; other aspects involve the integration of ordinary differential equations; applications include chaos and fractals as well as the unusual operation of some chemical engineering

equipment. Kubicek, M., and M. Marek, *Computational Methods in Bifurcation Theory and Dissipative Structures*, Springer-Verlag, Berlin (1983, 2012), give an excellent introduction to the subject and the details needed to apply the methods. A concise survey with some chemical engineering examples is given in Doherty, M. F., and J. M. Ottino, *Chem. Eng. Sci.* **43:** 139–183 (1988). Bifurcation results are closely connected with the stability of the steady states, which is essentially a transient phenomenon.

**Sensitivity Analysis** When one is solving differential equations, it is frequently necessary to know the solution as well as the sensitivity of the solution to the value of a parameter. Such information is useful when doing parameter estimation (to find the best set of parameters for a model) and for deciding if a parameter needs to be measured accurately. An added equation is created by differentiating the ordinary differential equation with respect to the parameter and solving that equation concurrently. See Finlayson et al. (2006) in General References.

**Molecular Dynamics** Special integration methods have been developed for molecular dynamics calculations owing to the structure of the equations. A very large number of equations are to be integrated, with the following form based on molecular interactions between molecules.

$$m_i \frac{d^2\mathbf{r}_i}{dt^2} = \mathbf{F}_i(\{\mathbf{r}\}) \quad \mathbf{F}_i(\{\mathbf{r}\}) = -\nabla V$$

The symbol $m_i$ is the mass of the $i$th particle, $\mathbf{r}_i$ is the position of the $i$th particle, $\mathbf{F}_i$ is the force acting on the $i$th particle, and $V$ is the potential energy that depends upon the location of all the particles (but not their velocities). Since the major part of the calculation lies in the evaluation of the forces, or potentials, a method must be used that minimizes the number of times the forces are calculated to move from one time to another time. Rewrite this equation in the form of an acceleration as

$$\frac{d^2\mathbf{r}_i}{dt^2} = \frac{1}{m}\mathbf{F}_i(\{\mathbf{r}\}) \equiv \mathbf{a}_i$$

In the Verlet method, this equation is written by using central finite differences (see Interpolation and Finite Differences). Note that the accelerations do not depend upon the velocities.

$$\mathbf{r}_i(t+\Delta t) = 2\mathbf{r}_i(t) - \mathbf{r}_i(t-\Delta t) + \mathbf{a}_i(t)\Delta t^2$$

The calculations are straightforward, and no explicit velocity is needed. The storage requirement is modest, and the precision is modest (it is a second-order method). Note that one must start the calculation with values of $\{\mathbf{r}\}$ at times $t$ and $t-\Delta t$.

In the Verlet velocity method, an equation is written for the velocity, too.

$$\frac{d\mathbf{v}_i}{dt} = \mathbf{a}_i$$

The trapezoid rule [see Numerical Integration (Quadrature)] is applied to obtain

$$\mathbf{v}_i(t+\Delta t) = \mathbf{v}_i(t) + \frac{1}{2}[\mathbf{a}_i(t) + \mathbf{a}_i(t+\Delta t)]\Delta t$$

The position of the particles is expanded in a Taylor series.

$$\mathbf{r}_i(t+\Delta t) = \mathbf{r}_i(t) + \mathbf{v}_i\Delta t + \frac{1}{2}\mathbf{a}_i(t)\Delta t^2$$

Beginning with values of $\{\mathbf{r}\}$ and $\{\mathbf{v}\}$ at time 0, one calculates the new positions and then the new velocities. This method is second-order in $\Delta t$ too. Molecular dynamics is used in chemical engineering for a variety of applications, including drug design, protein folding, nucleation and growth processes, and the phase behavior of polymeric, colloidal, and self-assembled systems [see Pamer, J. C., and P. G. Debenedettii, Recent Advances in Molecular Simulation: A Chemical Engineering Perspective, *AIChE J.* **61**, 370–383 (2015)]. For additional details about the method, see Hinchliffe, A., *Molecular Modelling for Beginners*, 2d ed., Wiley, New York, 2008; Jensen, J. H., *Molecular Modeling Basics*, CRC Press, Boca Raton, Fla., 2010; Leach, A. R., *Molecular Modelling: Principles and Applications*, 2d ed., Prentice Hall, Upper Saddle River, N.J., 2001; Schlick, T., *Molecular Modeling and Simulations*, 2d ed., Springer, New York, 2010. See https://en.wikipedia.org/wiki/List_of_software_for_molecular_mechanics_modeling for computer packages, especially the free programs LAMMPS (lammps.sandia.gov) and GROMACS (www.gromacs.org, especially for biological molecules).

See also Calvetti, D. E., and E. Somersalo, *Computational Mathematical Modeling: An Integrated Approach Across Scales*, SIAM, 2012, for methods to include phenomena that occur on different physical scales.

## ORDINARY DIFFERENTIAL EQUATIONS—BOUNDARY-VALUE PROBLEMS

Diffusion problems in one dimension lead to boundary-value problems. The boundary conditions are applied at two different spatial locations: at one side the concentration may be fixed and at the other side the flux may be fixed. Because the conditions are specified at two different locations, the problems are not initial-value in character. It is not possible to begin at one position and integrate directly because at least one of the conditions is specified somewhere else and there are not enough conditions to begin the calculation. Thus, methods have been developed especially for boundary-value problems.

Boundary-value methods provide a description of the solution either by providing values at specific locations or by an expansion in a series of functions. Thus, the key issues are the method of representing the solution, the number of points (i.e., the mesh) or the number of terms in the series, and how the approximation converges to the exact answer, i.e., how the error changes with the number of points or number of terms in the series. In addition, boundary conditions and nonlinear transport coefficients are handled differently in the various methods. These issues are discussed for each of the methods: finite difference, orthogonal collocation, and Galerkin finite element methods. Sometimes the solution has singularities or the domain is semi-infinite, and these situations require special treatment.

The first approach is to try to find an analytical solution. Flow in a pipe is governed by the equation

$$\frac{1}{r}\frac{d}{dr}\left(\mu r\frac{du}{dr}\right) = -\frac{\Delta P}{L}$$

where $u$ is the velocity, $r$ is the radial position, $\mu$ is the viscosity, and $\Delta P/L$ is the pressure drop per length. The solution is finite at the origin, $r = 0$, and takes the value zero at the radius of the pipe $R$. For a newtonian fluid, the viscosity is constant. This equation can be integrated once to obtain

$$r\frac{du}{dr} = -\frac{\Delta P}{\mu L}\frac{r^2}{2} + c_1 \quad \text{or} \quad \frac{du}{dr} = -\frac{\Delta P}{\mu L}\frac{r}{2} + \frac{c_1}{r}$$

and integrated again to get

$$u = -\frac{\Delta P}{\mu L}\frac{r^2}{4} + c_1 \ln r + c_2$$

Since the velocity is finite at the origin, $c_1$ is taken as zero; $c_2$ is taken as

$$c_2 = \frac{\Delta P}{\mu L}\frac{R^2}{4}$$

so that the velocity is zero at $r = R$. The solution is then

$$u = \frac{\Delta P}{4\mu L}(R^2 - r^2)$$

This problem requires no numerical methods. But if the viscosity were appropriate to a non-newtonian fluid and depended upon the shear rate, e.g., for a Bird-Carreau fluid

$$\mu = \frac{\eta_0}{\left[1 + \lambda\left(\frac{du}{dr}\right)^2\right]^{(1-n)/2}}$$

then numerical methods would be required, as described in this subsection.

**Finite Difference Method** To apply the finite difference method, we first spread grid points through the domain. Figure 3-48 shows a uniform mesh of $n$ points (nonuniform meshes are possible too). The unknown, here $c(x)$, at a grid point $x_i$ is assigned the symbol $c_i = c(x_i)$. The finite difference

**FIG. 3-48** Finite difference mesh; $\Delta x$ uniform.

method can be derived easily by using a Taylor expansion of the solution about this point. Expressions for the derivatives are

$$\left.\frac{dc}{dx}\right|_i = \frac{c_{i+1}-c_i}{\Delta x} - \left.\frac{d^2c}{dx^2}\right|_i \frac{\Delta x}{2} + \cdots, \quad \left.\frac{dc}{dx}\right|_i = \frac{c_i - c_{i-1}}{\Delta x} + \left.\frac{d^2c}{dx^2}\right|_i \frac{\Delta x}{2} + \cdots$$

$$\left.\frac{dc}{dx}\right|_i = \frac{c_{i+1}-c_{i-1}}{2\Delta x} - \left.\frac{d^3c}{dx^3}\right|_i \frac{\Delta x^2}{3!} + \cdots$$

The truncation error in the first two expressions is proportional to $\Delta x$, and the methods are said to be first-order. The truncation error in the third expression is proportional to $\Delta x^2$, and the method is said to be second-order. Usually the last equation is used to ensure the best accuracy. The finite difference representation of the second derivative is

$$\left.\frac{d^2c}{dx^2}\right|_i = \frac{c_{i+1} - 2\,c_i + c_{i-1}}{\Delta x^2} - \left.\frac{d^4c}{dx^4}\right|_i \frac{2\,\Delta x^2}{4!} + \cdots$$

The truncation error is proportional to $\Delta x^2$. To solve a differential equation, it is evaluated at a point $i$ and then these expressions are inserted for the derivatives.

***Example*** Consider the equation for convection, diffusion, and reaction in a tubular reactor.

$$\frac{1}{\mathrm{Pe}}\frac{d^2c}{dx^2} - \frac{dc}{dx} = \mathrm{Da}\,R(c)$$

Pe is the Peclet number and Da is the Damköhler number. The finite difference representation is

$$\frac{1}{\mathrm{Pe}}\frac{c_{i+1} - 2c_i + c_{i-1}}{\Delta x^2} - \frac{c_{i+1} - c_{i-1}}{2\Delta x} = \mathrm{Da}\,R(c_i)$$

This equation is written for $i = 2$ to $n - 1$, or the internal points. The equations would then be coupled but would also involve the values of $c_1$ and $c_n$ as well. These are determined from the boundary conditions.

If the boundary condition involves a derivative, it is important that the derivatives be evaluated using points that exist. Three possibilities exist; the first two are

$$\left.\frac{dc}{dx}\right|_1 = \frac{c_2 - c_1}{\Delta x}$$

$$\left.\frac{dc}{dx}\right|_1 = \frac{-3c_1 + 4c_2 - c_3}{2\Delta x}$$

The third alternative is to add a false point, outside the domain, as $c_0 = c(x = -\Delta x)$.

$$\left.\frac{dc}{dx}\right|_1 = \frac{c_2 - c_0}{2\Delta x}$$

Since this equation introduces a new variable $c_0$, another equation is needed and is obtained by writing the finite difference equation for $i = 1$ too. The sets of equations can be solved by using the Newton-Raphson method. The first form of the derivative gives a tridiagonal system of equations, and the standard routines for solving tridiagonal equations suffice. For the other two options, some manipulation is necessary to put them into a tridiagonal form.

Frequently, the transport coefficients, such as the diffusion coefficient or thermal conductivity, depend on the dependent variable, concentration, or temperature, respectively. Then the differential equation might look like

$$\frac{d}{dx}\left(D(c)\frac{dc}{dx}\right) = 0$$

This could be written as two equations.

$$-\frac{dJ}{dx} = 0 \qquad J = -D(c)\frac{dc}{dx}$$

Because the coefficient depends on $c$, the equations are more complicated. A finite difference method can be written in terms of the fluxes at the midpoints $i + 1/2$.

$$-\frac{J_{i+1/2} - J_{i-1/2}}{\Delta x} = 0 \qquad J_{i+1/2} = -D(c_{i+1/2})\frac{c_{i+1} - c_i}{\Delta x}$$

These are combined to give the complete equation.

$$\frac{D(c_{i+1/2})(c_{i+1} - c_i) - D(c_{i-1/2})(c_i - c_{i-1})}{\Delta x^2} = 0$$

This represents a set of nonlinear algebraic equations that can be solved with the Newton-Raphson method. However, in this case, a viable iterative strategy is to evaluate the transport coefficients at the last value and then solve

$$\frac{D(c_{i+1/2}^k)(c_{i+1}^{k+1} - c_i^{k+1}) - D(c_{i-1/2}^k)(c_i^{k+1} - c_{i-1}^{k+1})}{\Delta x^2} = 0$$

The advantage of this approach is that it is easier to program than a full Newton-Raphson method. If the transport coefficients do not vary radically, then the method converges. If the method does not converge, then it may be necessary to use the full Newton-Raphson method.

There are two common ways to evaluate the transport coefficient at the midpoint: Use the average value of the solution on each side to evaluate the diffusivity, or use the average value of the diffusivity on each side. Both methods have truncation error $\Delta x^2$. The spacing of the grid points need not be uniform. See Finlayson (1980) and Finlayson et al. (2006) in General References.

***Example*** A reaction diffusion problem is solved with the finite difference method.

$$\frac{d^2c}{dx^2} = \phi^2 c, \quad \frac{dc}{dx}(0) = 0 \quad c(1) = 1$$

The solution is derived for $\phi = 2$. It is solved several times, first with two intervals and three points (at $x = 0$, 0.5, 1), then with four intervals, then with eight intervals. The reason is that when an exact solution is not known, one must use several $\Delta x$ values and see that the solution converges as $\Delta x$ approaches zero. With two intervals, the equations are as follows. The points are $x_1 = 0$, $x_2 = 0.5$, and $x_3 = 1.0$; and the solutions at those points are $c_1$, $c_2$, and $c_3$, respectively. A false boundary is used at $x_0 = -0.5$.

$$\frac{c_0 - c_2}{2\Delta x} = 0, \quad \frac{c_0 - 2c_1 + c_2}{\Delta x^2} - \phi^2 c_1 = 0, \quad \frac{c_1 - 2c_2 + c_3}{\Delta x^2} - \phi^2 c_2 = 0, \quad c_3 = 1$$

The solution is $c_1 = 0.2857$, $c_2 = 0.4286$, and $c_3 = 1.0$. The problem is solved again with four and then eight intervals. The value of concentration at $x = 0$ takes the following values for different $\Delta x$ values. These values are extrapolated using the Richardson extrapolation technique to get $c(0) = 0.265718$. Using this value as the best estimate of the exact solution, the errors in the solution are tabulated versus $\Delta x$. Clearly the errors go as $\Delta x^2$ (decreasing by a factor of 4 when $\Delta x$ decreases by a factor of 2), thus validating the solution. The exact solution is 0.265802.

| $n-1$ | $\Delta x$ | $c(0)$ |
|---|---|---|
| 2 | 0.5 | 0.285714 |
| 4 | 0.25 | 0.271043 |
| 8 | 0.125 | 0.267131 |

| $n-1$ | $\Delta x$ | Error in $c(0)$ |
|---|---|---|
| 2 | 0.5 | 0.02000 |
| 4 | 0.25 | 0.00532 |
| 8 | 0.125 | 0.00141 |

**Finite Difference Methods Solved with Spreadsheets** A convenient way to solve the finite difference equations for simple problems is to use a computer spreadsheet. The equations for the problem solved in the example can be cast into the following form:

$$c_1 = \frac{2c_2}{2 + \phi^2\Delta x^2}$$

$$c_i = \frac{c_{i+1} + c_{i-1}}{2 + \phi^2\Delta x^2}$$

$$c_{n+1} = 1$$

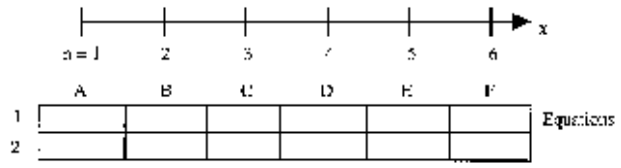

**FIG. 3-49** Finite difference method using spreadsheets.

Let us solve the problem using 6 nodes, or 5 intervals. Then the connection between the cell in the spreadsheet and the nodal value is shown in Fig. 3-49. The following equations are placed into the various cells.

A1: = 2*B1/(2.+(phi*dx)**2)
B1: = (A1 + C1)/(2.+(phi*dx)**2)
F1: = 1.

The equation in cell B1 is copied into cells C1 through E1. Then turn on the iteration scheme in the spreadsheet and watch the solution converge. Whether convergence is achieved can depend on how you write the equations, so some experimentation may be necessary. Theorems for convergence of the successive substitution method are useful in this regard.

**Orthogonal Collocation** The orthogonal collocation method has found widespread application in chemical engineering, particularly for chemical reaction engineering. In the collocation method, the dependent variable is expanded in a series of orthogonal polynomials. See Interpolation: Lagrange Interpolation Formulas.

$$c(x)=\sum_{m=0}^{N} a_m P_m(x)$$

The differential equation is evaluated at certain collocation points. The collocation points are the roots to an orthogonal polynomial, as first used by Lanczos [Lanczos, C., *J. Math. Phys.* **17:**123–199 (1938); and Lanczos, C., *Applied Analysis*, Prentice Hall, Upper Saddle River, N.J., 1956]. A major improvement was proposed by Villadsen and Stewart [Villadsen, J. V., and W. E. Stewart, *Chem. Eng. Sci.* **22:**1483–1501 (1967)], who proposed that the entire solution process be done in terms of the solution at the collocation points rather than the coefficients in the expansion. This method is especially useful for reaction diffusion problems that frequently arise when modeling chemical reactors. It is highly efficient when the solution is smooth, but the finite difference method is preferred when the solution changes steeply in some region of space. The error decreases very rapidly as $N$ is increased since it is proportional to $[1/(1-N)]^{N-1}$. See Finlayson (1980) in General References.

**Galerkin Finite Element Method** In the finite element method, the domain is divided into elements, and an expansion is made for the solution on each finite element (see Interpolation: Finite Element Method). In the Galerkin finite element method, an additional idea is introduced: the Galerkin method is used to solve the equation. The Galerkin method is explained using the equations for reaction and diffusion in a porous catalyst pellet.

$$\frac{d^2c}{dx^2}=\phi^2 R(c)$$
$$\frac{dc}{dx}(0)=0,\quad c(1)=1$$

The unknown solution is expanded in a series of known functions $\{b_i(x)\}$ with unknown coefficients $\{a_i\}$.

$$c(x)=\sum_{i=1}^{NT} a_i b_i(x)$$

The trial solution is substituted into the differential equation to obtain the residual.

$$\text{Residual}=\sum_{i=1}^{NT} a_i \frac{d^2 b_i}{dx^2}-\phi^2 R\left[\sum_{i=1}^{NT} a_i b_i(x)\right]$$

The residual is then made orthogonal to the set of basis functions.

$$\int_0^1 b_j(x)\left\{\sum_{i=1}^{NT} a_i \frac{d^2 b_i}{dx^2}-\phi^2 R\left[\sum_{i=1}^{NT} a_i b_i(x)\right]\right\}dx=0 \quad j=1,\ldots,NT$$

This is the process that makes the method a Galerkin method. The basis for the orthogonality condition is that any function that is orthogonal to each member of a complete set is zero. The residual is being made orthogonal; and if the basis functions are complete and you use infinitely many of them, then the residual is zero. Once the residual is zero, the problem is solved.

This equation is integrated by parts to give the following equation:

$$-\sum_{i=1}^{NT}\int_0^1 \frac{db_j}{dx}\frac{db_i}{dx}dx a_i=\phi^2\int_0^1 b_j(x)R\left[\sum_{i=1}^{NT} a_i b_i(x)\right]dx \quad j=1,\ldots,NT-1 \qquad (3\text{-}66)$$

This equation defines the Galerkin method, and a solution that satisfies this equation (for all $j = 1, \ldots, \infty$) is called a *weak solution.* For an approximate solution, the equation is written once for each member of the trial function, $j = 1, \ldots, NT - 1$, and the boundary condition is applied.

$$\sum_{i=1}^{NT} a_i b_i(1)=c_B$$

The Galerkin finite element method results when the Galerkin method is combined with a finite element trial function. The domain is divided into elements separated by nodes, as in the finite difference method. The solution is approximated by a linear (or sometimes quadratic) function to provide the Galerkin finite element equations. For example, with the grid shown in Fig. 3-48, a linear interpolation would be used between points $x_i$ and $x_{i+1}$.

$$c(x)=c_i(1-u)+c_{i+1}u \qquad u\equiv\frac{x-x_i}{x_{i+1}-x_i}$$

A finite element method based on these functions would have an error proportional to $\Delta x^2$. The finite element representations for the first derivative and second derivative are the same as in the finite difference method, but this is not true for other functions or derivatives. With quadratic finite elements, take the region from $x_{i-1}$ and $x_{i+1}$ as one element with $x = x_{i-1}$ at $u = 0$, $x = x_i$ at $u = ½$, and $x = x_{i+1}$ at $u = 1$. Then the interpolation would be

$$c(x)=c_{i-1}N_1(u)+c_i N_2(u)+c_{i+1}N_3(u)$$
$$N_1(u)=2(u-1)\left(u-\frac{1}{2}\right)\quad N_2(u)=4u(1-u)$$
$$N_3(u)=2u\left(u-\frac{1}{2}\right)$$

A finite element method based on these functions would have an error proportional to $\Delta x^3$. Thus, it would converge faster than one based on linear interpolation.

**Adaptive Meshes** In many two-point boundary-value problems, the difficulty in the problem lies in the formation of a boundary-layer region, or a region in which the solution changes very dramatically. In such cases, it is prudent to use small mesh spacing there, with either the finite difference method or the finite element method. If the region is known a priori, small mesh spacings can be assumed at the boundary layer. If the region is not known, however, other techniques must be used. These techniques are known as adaptive mesh techniques. The mesh size is made small where some property of the solution is large. For example, if the truncation error of the method is $n$th-order, then the $n$th-order derivative of the solution is evaluated and a small mesh is used where it is large. Alternatively, the residual (the differential equation with the numerical solution substituted into it) can be used as a criterion. It is also possible to define the error that is expected from a method one order higher and one order lower. Then a decision about whether to increase or decrease the order of the method can be made, taking into account the relative work of the different orders. This provides a method of adjusting both the mesh spacing ($\Delta x$, or sometimes called $h$) and the degree of polynomial ($p$). Such methods are called *h-p* methods. Many finite element programs have the capability to do this mesh refinement automatically.

**Singular Problems and Infinite Domains** If the solution being sought has a singularity, it may be difficult to find a good numerical solution. Sometimes even the location of the singularity may not be known. One method of solving such problems is to refine the mesh near the singularity, relying on the better approximation due to a smaller $\Delta x$. Another approach is to incorporate the singular trial function into the approximation. Thus, if the solution approaches $f(x)$ as $x$ goes to zero and $f(x)$ becomes infinite, one may define a new variable $u(x) = y(x) - f(x)$ and derive an equation for $u$. The differential equation is more complicated, but the solution is better near the singularity. See Press et al. (2007) in General References.

Sometimes the domain is semi-infinite, as in boundary-layer flow. The domain can be transformed from the $x$ domain $(0 - \infty)$ to the $\eta$ domain $(1 - 0)$ using the transformation $\eta = \exp(-x)$. Another approach is to use a variable mesh, perhaps with the same transformation. For example, use $\eta = \exp(-\beta x)$ and a constant mesh size in $\eta$; the value of $\beta$ is found experimentally. Still another approach is to solve on a finite mesh in which the last point is far enough away that its location does not influence the solution. A location that is far enough away must be found by trial and error.

Packages to solve boundary-value problems are available on the Internet. On the NIST web page http://gams.nist.gov/Problem.html insert "ordinary differential equations" to find packages for boundary-value problems. On the Netlib website http://www.netlib.org/ search on "boundary-value problem." Any spreadsheet that has an iteration capability can be used with the finite difference method. Some packages for partial differential equations also have a capability for solving one-dimensional boundary-value problems (e.g., Comsol Multiphysics).

## NUMERICAL SOLUTION OF INTEGRAL EQUATIONS

This subsection considers a method of solving numerically the Fredholm integral equation of the second kind:

$$u(x) = f(x) + \lambda \int_a^b k(x,t)\,u(t)\,dt \quad \text{for } u(x) \tag{3-67}$$

The method discussed arises because a definite integral can be closely approximated by any of several numerical integration formulas (each of which arises by approximating the function by some polynomial over an interval). Thus the definite integral in Eq. (3-67) can be replaced by an integration formula, and Eq. (3-67) may be written

$$u(x) = f(x) + \lambda (b-a)\left[\sum_{i=1}^{n} c_i k(x,t_i) u(t_i)\right] \tag{3-68}$$

where $t_1, \ldots, t_n$ are points of subdivision of the $t$ axis, $a \le t \le b$, and the $c$'s are coefficients whose values depend upon the type of numerical integration formula used. Now Eq. (3-68) must hold for all values of $x$, $a \le x \le b$; so it must hold for $x = t_1, x = t_2, \ldots, x = t_n$. Substituting for $x$ successively $t_1, t_2, \ldots, t_n$ and setting $u(t_i) = u_i$ and $f(t_i) = f_i$, we get $n$ linear algebraic equations for the $n$ unknowns $u_1, \ldots, u_n$. That is,

$$u_i = f_i + \lambda(b-a)[c_1 k(t_i, t_1)u_1 + c_2 k(t_i, t_2)u_2 + \cdots + c_n k(t_i, t_n)u_n] \qquad i = 1, 2, \ldots, n$$

These $u_j$ may be solved for by the methods under Numerical Solution of Linear Equations and Associated Problems and substituted into Eq. (3-68) to yield an approximate solution for Eq. (3-67).

Because of the work involved in solving large systems of simultaneous linear equations it is desirable that only a small number of $u$ values be computed. Thus the gaussian integration formulas are useful because of the economy they offer.

Solutions for Volterra equations are done in a similar fashion, except that the solution can proceed point by point or in small groups of points depending on the quadrature scheme. See Linz, P., *Analytical and Numerical Methods for Volterra Equations*, SIAM, Philadelphia, Penn., 1985. There are methods that are analogous to the usual methods for integrating differential equations (Runge-Kutta, predictor-corrector, Adams methods, etc.). Explicit methods are fast and efficient until the time step is very small to meet the stability requirements. Then implicit methods are used, even though sets of simultaneous algebraic equations must be solved. The major part of the calculation is the evaluation of integrals, however, so that the added time to solve the algebraic equations is not excessive. Thus, implicit methods tend to be preferred. Volterra equations of the first kind are not well posed, and small errors in the solution can have disastrous consequences. The boundary element method uses Green's functions and integral equations to solve differential equations. See Brebbia, C. A., and J. Dominguez, *Boundary Elements—An Introductory Course*, 2d ed., Computational Mechanics Publications, Southhampton, UK, 1992; Poljak, D., and C. A. Brebbia, *Boundary Element Methods for Electrical Engineers*, WIT Press, Ashurst, UK, 2005.

## MONTE CARLO SIMULATIONS

Some physical problems, such as those involving the interaction of molecules, are usually formulated as integral equations. Monte Carlo methods are especially well suited to their solution. This section cannot give a comprehensive treatment of such methods, but their use in calculating the value of an integral will be illustrated. Suppose we wish to calculate the integral

$$G = \int_{\Omega_0} g(x) f(x)\,dx$$

where the distribution function $f(x)$ satisfies

$$f(x) \ge 0, \quad \int_{\Omega_0} f(x)\,dx = 1$$

The distribution function $f(x)$ can be taken as constant, for example, $1/\Omega_0$. We choose variables $x_1, x_2, \ldots, x_N$ randomly from $f(x)$ and form the arithmetic mean

$$G_N = \frac{1}{N}\sum_i g(x_i)$$

The quantity $G_N$ is an estimation of $G$, and the fundamental theorem of Monte Carlo guarantees that the expected value of $G_N$ is $G$, if $G$ exists (Kalos, M. H., and P. A. Whitlock, *Monte Carlo Methods*, vol. 1, Wiley, New York, 1986). The error in the calculation is given by

$$\varepsilon = \frac{\sigma_1}{N^{1/2}}$$

where $\sigma_1^2$ is calculated from

$$\sigma_1^2 = \int_{\Omega_0} g^2(x)\, f(x)\,dx - G^2$$

Thus the number of terms needed to achieve a specified accuracy $\varepsilon$ can be calculated once an estimate of $\sigma_1^2$ is known.

$$N = \frac{\sigma_1^2}{\varepsilon^2}$$

Various methods, such as influence sampling, can be used to reduce the number of calculations needed. See also Lapeyre, B., *Introduction to Monte-Carlo Methods for Transport and Diffusion Equations*, Oxford University Press, London, 2003; Liu, J. S., *Monte Carlo Strategies in Scientific Computing*, Springer, New York, 2008; and Thomopoulos, N. T., *Essentials of Monte Carlo Simulation: Statistical Methods for Building Simulation Models*, Springer, New York, 2013. Some computer programs are available that perform simple Monte Carlo calculations using Microsoft Excel. Monte Carlo methods for molecular simulation lead to an equilibrium configuration of the molecules. Thus, the approach to that equilibrium is not modeled, and this is an advantage over molecular dynamics (see below) when the equilibrium configuration is the desired result, since the Monte Carlo method is faster. A good open-source Monte Carlo program is CASSANDRA at the University of Notre Dame.

## NUMERICAL SOLUTION OF PARTIAL DIFFERENTIAL EQUATIONS

The numerical methods for partial differential equations can be classified according to the type of equation (see Partial Differential Equations): parabolic, elliptic, and hyperbolic. This section uses the finite difference method to illustrate the ideas, and these results can be programmed for simple problems. For more complicated problems, however, it is common to rely on computer packages. Thus, some discussion is given to the issues that arise in using computer packages. These methods are used in modeling microfluidics (with small Reynolds numbers) and turbulence (with large Reynolds numbers).

**Parabolic Equations in One Dimension** By combining the techniques applied to initial-value problems and boundary-value problems, it is possible to easily solve parabolic equations in one dimension. The method is often called the *method of lines*. It is illustrated here using the finite difference method, but the Galerkin finite element method and the orthogonal collocation method can also be combined with initial-value methods in similar ways. The analysis is done by example. The finite volume method is described under Hyperbolic Equations.

***Example*** Consider the diffusion equation, with boundary- and initial-value conditions.

$$\frac{\partial c}{\partial t} = D\frac{\partial^2 c}{\partial x^2}$$

$$c(x, 0) = 0,$$

$$c(0, t) = 1, \qquad c(1, t) = 0$$

We denote by $c_i$ the value of $c(x_i, t)$ at any time. Thus, $c_i$ is a function of time, and differential equations in $c_i$ are ordinary differential equations.

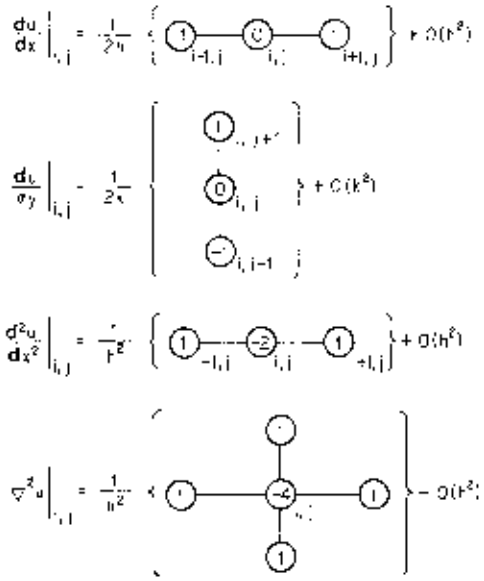

**FIG. 3-50** Computational molecules. $h = \Delta x = \Delta y$.

By evaluating the diffusion equation at the $i$th node and replacing the derivative with a finite difference equation, the following working equation is derived for each node $i$, $i = 2, \ldots, n$ (see Fig. 3-50).

$$\frac{dc_i}{dt} = D\,\frac{c_{i+1} - 2c_i + c_{i-1}}{\Delta x^2}$$

This can be written in the general form of a set of ordinary differential equations by defining matrix **AA**.

$$\frac{d\mathbf{c}}{dt} = \mathbf{AA}\mathbf{c}$$

This set of ordinary differential equations can be solved using any of the standard methods, and the stability of the integration of these equations is governed by the largest eigenvalue of **AA**. When Euler's method is used to integrate in time, the equations become

$$\frac{c_i^{n+1} - c_i^n}{\Delta t} = D\,\frac{c_{i+1}^n - 2c_i^n + c_{i-1}^n}{\Delta x^2}$$

where $c_i^n = c(x_i, t^n)$. Notice that if the solution is known at every point at one time $n$, then it is a straightforward calculation to find the solution at every point at the new time $n + 1$.

If Euler's method is used for integration, the time step is limited by

$$\Delta t \le \frac{2}{|\lambda|_{\max}}$$

whereas if the Runge-Kutta-Fehlberg method is used, the 2 in the numerator is replaced by 3.0. The largest eigenvalue of **AA** is bounded by Gerschgorin's theorem.

$$|\lambda|_{\max} \le \max_{2<j<n} \sum_{i=2}^{n} |\mathbf{AA}_{ji}| = \frac{4D}{\Delta x^2}$$

This gives the well-known stability limit

$$\Delta t\,\frac{D}{\Delta x^2} \le \frac{1}{2}$$

The smallest eigenvalue is independent of $\Delta x$ (it is $D\pi^2/L^2$) so that the ratio of largest to smallest eigenvalue is proportional to $1/\Delta x^2$. Thus, the problem becomes stiff as $\Delta x$ approaches zero. See Eq. (3-65).

The effect of the increased stiffness is that a smaller and smaller time step ($\Delta t$) must be taken as the mesh is refined ($\Delta x^2 \to 0$). At the same time, the number of points is increasing, so the computation becomes very lengthy. Implicit methods are used to overcome this problem.

Write a finite difference form for the time derivative and average the right-hand sides, evaluated at the old and new times.

$$\frac{c_i^{n+1} - c_i^n}{\Delta t} = D(1-\theta)\frac{c_{i+1}^n - 2c_i^n + c_{i-1}^n}{\Delta x^2} + D\theta\,\frac{c_{i+1}^{n+1} - 2c_i^{n+1} + c_{i-1}^{n+1}}{\Delta x^2}$$

Now the equations are of the form

$$-\frac{D\Delta t\theta}{\Delta x^2}c_{i+1}^{n+1} + \left(1 + 2\frac{D\,\Delta t\theta}{\Delta x^2}\right)c_i^{n+1} - \frac{D\Delta t\theta}{\Delta x^2}c_{i-1}^{n+1} = c_i^n + \frac{D\Delta t\,(1-\theta)}{\Delta x^2}(c_{i+1}^n - 2c_i^n + c_{i-1}^n)$$

and require solving a set of simultaneous equations, which have a tridiagonal structure. Using $\theta = 0$ gives the Euler method (as above), $\theta = 0.5$ gives the Crank-Nicolson method, and $\theta = 1$ gives the backward Euler method. The Crank-Nicolson method is also the same as applying the trapezoid rule to do the integration. The stability limit is given by

$$\Delta t\,\frac{D}{\Delta x^2} \le \frac{0.25}{1 - 2\theta}$$

The price of using implicit methods is that one now has a system of equations to solve at each time step, and the solution methods are more complicated (particularly for nonlinear problems) than the straightforward explicit methods. Phenomena that happen quickly can also be obliterated or smoothed over by using a large time step, so implicit methods are not suitable in all cases. The engineer must decide if she or he wants to track those fast phenomena, and choose an appropriate method that handles the time scales that are important in the problem.

Other methods can be used in space, such as the finite element method, the orthogonal collocation method, or the method of orthogonal collocation on finite elements. One simply combines the methods for ordinary differential equations (see Ordinary Differential Equations—Boundary-Value Problems) with the methods for initial-value problems (see Numerical Solution of Ordinary Differential Equations as Initial-Value Problems). Fast Fourier transforms can also be used on regular grids (see Fast Fourier Transform).

**Elliptic Equations** Elliptic equations can be solved with both finite difference and finite element methods. One-dimensional elliptic problems are two-point boundary-value problems. Two- and three-dimensional elliptic problems are often solved with iterative methods when the finite difference method is used and with direct methods when the finite element method is used. So there are two aspects to consider: how the equations are discretized to form sets of algebraic equations and how the algebraic equations are then solved.

The prototype elliptic problem is steady-state heat conduction or diffusion

$$k\left(\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2}\right) = Q$$

possibly with a heat generation term per unit volume $Q$. The boundary conditions taken here are $T = f(x, y)$ on the boundary ($S$) with $f$ a known function. Illustrations are given for constant thermal conductivity $k$ while $Q$ is a known function of position. The finite difference formulation is given using the following nomenclature:

$$T_{i,j} = T(i\,\Delta x, j\,\Delta y)$$

The finite difference formulation is then (see Fig. 3-50)

$$\frac{T_{i+1,j} - 2T_{i,j} + T_{i-1,j}}{\Delta x^2} + \frac{T_{i,j+1} - 2T_{i,j} + T_{i,j-1}}{\Delta y^2} = Q_{i,j} \qquad T_{i,j} = f(x_i, y_j) \text{ on } S \tag{3-69}$$

If the boundary is parallel to a coordinate axis, any derivative is evaluated as in the section on boundary-value problems, using either a one-sided, centered difference or a false boundary. If the boundary is more irregular and not parallel to a coordinate line, then more complicated expressions are needed and the finite element method may be the better method.

Equation (3-69) provides a set of linear equations that must be solved. These equations and their boundary conditions may be written in matrix form as

$$\mathbf{At} = \mathbf{f}$$

where **t** is the set of temperatures at all the points, **f** is the set of heat generation terms at all points, and **A** is formed from the coefficients of $T_{ij}$ in Eq. (3-69).

The solution can be obtained simply by solving the set of linear equations. For three-dimensional problems, the matrix **A** is sparse, and iterative methods are used. These include Gauss-Seidel, alternating direction, overrelaxation methods, conjugate gradient, and multigrid methods. In Gauss-Seidel methods, one writes the equation for $T_{ij}$ in terms of the other temperatures and cycles through all the points over and over. In the alternating direction method, one solves along one line (that is, $x$ = constant), keeping the side values fixed, and then repeats this for all lines, and then repeats the process. Multigrid methods solve the problem on successively refined grids, which has advantages for both convergence and error estimation. Conjugate gradient methods frequently use a preconditioned matrix. The equation is multiplied by another matrix, which is chosen so that the resulting problem is easier to solve than the original one. Finding such matrices is an art, but it can speed convergence. The generalized minimal residual method is described in http://mathworld.wolfram.com/ GeneralizedMinimalResidualMethod.html. Additional resources can be found at http://www.netlib.org/linalg/html_templates/Templates.html. When the problem is nonlinear, the iterative methods may not converge, or the mesh may have to be refined before they converge, so some experimentation is sometimes necessary.

Spreadsheets can be used to solve two-dimensional problems on rectangular grids. The equation for $T_{ij}$ is obtained by rearranging Eq. (3-69).

$$2\left(1+\frac{\Delta x^2}{\Delta y^2}\right)T_{i,j}=T_{i+1,j}+T_{i-1,j}+\frac{\Delta x^2}{\Delta y^2}(T_{i,j+1}+T_{1,j-1})-\Delta x^2\frac{Q_{i,j}}{k}$$

This equation is inserted into a cell and copied throughout the space represented by all the cells; when the iteration feature is turned on, the solution is obtained.

The Galerkin finite element method (FEM) is useful for solving elliptic problems and is particularly effective when the domain or geometry is irregular. As an example, cover the domain with triangles and define a trial function on each triangle. The trial function takes the value 1.0 at one corner and the value 0.0 at the other corners and is linear in between. For a triangle with corners at $(x, y) = (0, 0.58)$, $(0.66, 0)$, and $(1, 0.66)$ one of three trial functions is shown in Fig. 3-51. These trial functions on each triangle are pieced together to give a trial function on the whole domain. General treatments of the finite element method are available (see references). The steps in the solution method are similar to those described for boundary-value problems, except now the problems are much bigger so that the numerical analysis must be done very carefully to be efficient. Most engineers, however, just use a finite element program without generating it. There are three major caveats that must be addressed. First, the solution is dependent on the mesh laid down, and the only way to assess the accuracy of the solution is to solve the problem with a more refined mesh. Second, the solution obeys the shape of the trial function inside the element. Thus, if linear functions are used on triangles, a three-dimensional view of the solution, plotting the solution versus $x$ and $y$, consists of a series of triangular planes joined together at the edges, as in a geodesic dome. Third, the Galerkin finite element method is applied to both the differential equations and the boundary conditions. Computer programs are usually quite general and may allow the user to specify boundary conditions that are not realistic. Also, natural boundary conditions are satisfied if no other boundary condition (ones involving derivatives) is set at a node. Thus, the user of finite element codes must be very clear what boundary conditions and differential equations are built into the computer code. When the problem is nonlinear, the Newton-Raphson method is used to iterate from an initial guess. Nonlinear problems lead to complicated integrals to evaluate, and they are usually evaluated using gaussian quadrature.

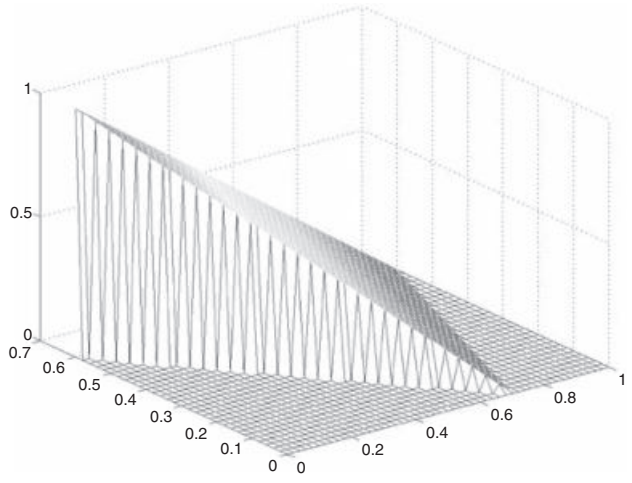

**FIG. 3-51** Trial functions for Galerkin finite element method: a linear polynomial on a triangle.

One nice feature of the finite element method is the use of natural boundary conditions. It may be possible to solve the problem on a domain that is shorter than needed to reach some limiting condition (such as at an outflow boundary). The externally applied flux is still applied at the shorter domain, and the solution *inside* the truncated domain is still valid. Examples are given in Chang, M. W., and B. A. Finlayson, *Int. J. Num. Methods Eng.* **15,** 935–942 (1980), and Finlayson, B. A., *Numerical Methods for Problems with Moving Fronts*, Ravenna Park Publishing, Seattle, Wash. (1992). The effect of this is to allow solutions in domains that are smaller, thus saving computation time and permitting the solution in semi-infinite domains.

The trial functions in the finite element method are not limited to linear ones. Quadratic functions and even higher-order functions are frequently used. The same considerations hold as for boundary-value problems: The higher-order trial functions converge faster, but require more work. It is possible to refine both the mesh $h$ and the power of polynomial in the trial function $p$ in an $h$-$p$ method. Some problems have constraints on some of the variables. For flow problems, the pressure must usually be approximated by using a trial function that is one order lower than the polynomial used to approximate the velocity.

**Hyperbolic Equations** The most common situation yielding hyperbolic equations involves unsteady phenomena with convection. Two typical equations are the convective diffusive equation

$$\frac{\partial c}{\partial t}+u\frac{\partial c}{\partial x}=D\frac{\partial^2 c}{\partial x^2}$$

and the chromatography equation. (See Partial Differential Equations.) If the diffusion coefficient is zero, the convective diffusion equation is hyperbolic. If $D$ is small, the phenomenon may be essentially hyperbolic, even though the equations are parabolic. Thus the numerical methods for hyperbolic equations may be useful even for special parabolic equations.

Equations for several methods are given here. If the convective term is treated with a centered difference expression, the solution exhibits oscillations from node to node, and these go away only if a very fine grid is used. The simplest way to avoid the oscillations with a hyperbolic equation is to use upstream derivatives. If the flow is from left to right, this would give

$$\frac{dc_i}{dt}+u\frac{c_i-c_{i-1}}{\Delta x}=D\frac{c_{i+1}-2c_i+c_{i-1}}{\Delta x^2}$$

The effect of using upstream derivatives is to add artificial or numerical diffusion to the model. This can be ascertained by rearranging the finite difference form of the convective diffusion equation

$$\frac{dc_i}{dt}+u\frac{c_{i+1}-c_{i-1}}{2\Delta x}=\left(D+\frac{u\Delta x}{2}\right)\frac{c_{i+1}-2c_i+c_{i-1}}{\Delta x^2}$$

Thus the diffusion coefficient has been changed from

$$D \text{ to } D+\frac{u\Delta x}{2}$$

Alternatively, the diffusion coefficient has been multiplied by the factor

$$D'=D\left(1+\frac{u\Delta x}{2D}\right)=D\left(1+\frac{\mathrm{Pe}_{\mathrm{cell}}}{2}\right)$$

where $\mathrm{Pe}_{\mathrm{cell}}=\dfrac{u\Delta x}{D}=\dfrac{uL}{D}\dfrac{\Delta x}{L}=\mathrm{Pe}\dfrac{\Delta x}{L}$ is called the *cell Peclet number*. When the diffusion coefficient is very small (or diffusion is slow compared with convection), the Peclet number will be large. In that case, extraneous diffusion will be included in the solution unless the mesh size (denoted by $\Delta x$) is small compared with the characteristic length of the problem. To avoid this problem (by keeping the factor small), very fine meshes must be used, and the smaller the diffusion coefficient, the smaller the required mesh size.

A variety of other methods are used to obtain a good solution without using extremely fine meshes. The flux correction methods keep track of the flux of material into and out of a cell (from one node to another) and put limits on the flux to make sure that no more material leaves the cell than is there originally plus the input amount. See Finlayson, B. A., *Numerical*

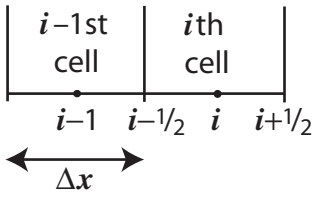

**FIG. 3-52** Nomenclature for finite volume method.

*Methods for Problems with Moving Fronts*, Ravenna Park Publishing, Seattle, Wash., 1992, for many examples.

All the methods have a limit to the time step that is set by the convection term. Essentially, the time step should not be so big as to take the material farther than it can go at its velocity. This is usually expressed as a *Courant number limitation*.

$$\mathrm{Co} = \frac{u\Delta t}{\Delta x} \le 1$$

Some methods require a smaller limit, depending upon the amount of diffusion present (see Finlayson, 1992, Appendix).

In the finite element method, Petrov-Galerkin methods are used to minimize the unphysical oscillations. The Petrov-Galerkin method essentially adds a small amount of diffusion in the flow direction to smooth the unphysical oscillations. The amount of diffusion is usually proportional to $\Delta x$ so that it becomes negligible as the mesh size is reduced. The value of the Petrov-Galerkin method lies in being able to obtain a smooth solution when the mesh size is large, so that the computation is feasible. This is not so crucial in one-dimensional problems, but it is essential in two- and three-dimensional problems and purely hyperbolic problems.

**Finite Volume Methods** Finite volume methods are utilized extensively in computational fluid dynamics. An excellent presentation is by LeVeque (2002). In this method, a mass balance is made over a cell, accounting for the change in what is in the cell, and the flow in and out. Figure 3-52 illustrates the geometry of the *i*th cell. A mass balance made on this cell (with area $A$ perpendicular to the paper) is

$$A\,\Delta x\,(c_i^{n+1} - c_i^n) = \Delta t\,A\,(J_{i-1/2} - J_{i+1/2})$$

where $J$ is the flux due to convection and diffusion, positive in the $+x$ direction.

$$J = uc - D\frac{\partial c}{\partial x},\quad J_{i-1/2} = u_{i-1/2}c_{i-1/2} - D\frac{c_i - c_{i-1}}{\Delta x}$$

The concentration at the edge of the cell is taken as

$$c_{i-1/2} = \frac{1}{2}(c_i + c_{i-1})$$

Rearrangement for the case when the velocity $u$ is the same for all nodes gives

$$\frac{c_i^{n+1} - c^n{}_i}{\Delta t} + \frac{u(c_{i+1} - c_{i-1})}{2\Delta x} = \frac{D}{\Delta x^2}(c_{i+1} - 2c_i + c_{i+1})$$

This is the same equation obtained by using the finite difference method. This coincidence occurs only when the velocity is constant, which isn't usually true. In two and three dimensions, the mesh need not be rectangular, as long as it is possible to compute the velocity normal to an edge of the cell. The finite volume method is useful for applications involving filling, such as injection molding, when only part of the cell is filled with fluid. Such applications do involve some approximations, since the interface is not tracked precisely, but they are useful engineering approximations.

**Parabolic Equations in Two or Three Dimensions** Computations become much more lengthy when there are two or more spatial dimensions. For example, we may have the unsteady heat conduction equation

$$\rho C_p \frac{\partial T}{\partial t} = k\left(\frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2}\right) - Q$$

Most engineers use computer packages to solve such problems. If there is both convection and diffusion in the problem, the same considerations apply: A fine mesh is needed when the Peclet number is large. The upstream weighting and Petrov-Galerkin methods can be used, but it is important to apply the smoothing only in the direction of flow, since smoothing in the direction transverse to the flow direction would be incorrect. Some transverse smoothing is unavoidable, but the engineer needs to be sure that the smoothing is just enough to allow a good solution without creating large errors. See Finlayson (1980) in General References; Kuzmin, D., and J. Hämäläinen, *Finite Element Methods for Computational Fluid Dynamics: A Practical Guide*, SIAM-Soc. Ind. Appl. Math., 2014; and Layton, W., *Introduction to the Numerical Analysis of Incompressible Viscous Flows*, SIAM, 2008.

**Computer Software** When one is choosing computer software to solve a problem, there are a number of important considerations. The first decision is whether to use an approximate, engineering flow model, developed from correlations, or to solve the partial differential equations that govern the problem. Correlations are quick and easy to apply, but they may not be appropriate to the problem or give the needed detail. When one is using a computer package to solve partial differential equations, the first task is always to generate a mesh covering the problem domain. This is not a trivial task, and special methods have been developed to permit importation of a geometry from a computer-aided design (CAD) program. Then the mesh must be created automatically. If the boundary is irregular, the finite element method is especially well suited, although special embedding techniques can be used in finite difference methods (which are designed to be solved on rectangular meshes). Another capability to consider is the ability to track free surfaces that move during the computation. This phenomenon introduces the same complexity that occurs in problems with a large Peclet number, with the added difficulty that the free surface moves between mesh points and improper representation can lead to unphysical oscillations. The method used to solve the equations is important, and both explicit and implicit methods (as described above) can be used. Implicit methods may introduce unacceptable extra diffusion, so the engineer needs to examine the solution carefully. The methods used to smooth unphysical oscillations from node to node are also important, and the engineer needs to verify that the added diffusion or smoothing does not give inaccurate solutions. Since current-day problems are mostly nonlinear, convergence is always an issue since the problems are solved iteratively. Robust programs provide several methods for convergence, each of which is best in some circumstance or other. It is wise to have a program that includes many iterative methods. If the iterative solver is not very robust, the only recourse to solving a steady-state problem may be to integrate the time-dependent problem to steady state. The solution time may be long, and the final result may be further from convergence than would be the case if a robust iterative solver were used.

A variety of computer programs are available on the Internet, some free. First consider general-purpose programs. The website http://www.netlib.org/pdes/index.html lists programs for 2D elliptic partial differential equations as well as Clawpack for hyperbolic systems of equations from LeVeque (2002). On the NIST website http://gams.nist.gov/ search on "partial differential equations." Lau (2007) provides many programs in C++ (also see http://numerical.recipes /). The multiphysics program Comsol Multiphysics also solves many standard equations arising in mathematical physics.

Computational fluid dynamics (CFD) programs are more specialized, and most have been designed to solve sets of equations that are appropriate to specific industries. They can then include approximations and correlations for some features that would be difficult to solve for directly. ANSYS (http://www.ansys.com) is a major program having incorporated both Fluent and CFX. Comsol Multiphysics (http://www.comsol.com) is particularly useful because it incorporates many different types of physics (and equations), has a convenient graphical-user interface, permits easy mesh generation and refinement (including adaptive mesh refinement), allows the user to add phenomena and equations easily, permits solution by continuation methods (thus enhancing convergence), and has extensive graphical output capabilities. Other packages are also available (see http://cfd-online.com/), and these may contain features and correlations specific to the engineer's industry. One important point to note is that for turbulent flow, all the programs contain approximations, using the $k$-epsilon models of turbulence, or large eddy simulations; the direct numerical simulation of turbulence is too slow to apply to very big problems, although it does give insight (independent of any approximations) that is useful for interpreting turbulent phenomena. Thus, the method used to include those turbulent correlations is important, and the method also may affect convergence or accuracy.

## FAST FOURIER TRANSFORM

The discrete Fourier transform can be used to differentiate a function, and this is used in the spectral method for solving differential equations as well as in modeling turbulent flow. Gottlieb, D., and S. A. Orszag, *Numerical Analysis*

*of Spectral Methods: Theory and Applications*, SIAM, Philadelphia, Penn., 1977, discusses why they work; Trefethen, L. N., *Spectral Methods in Matlab*, SIAM, Philadelphia, Penn., 2000, shows how to use them in MATLAB. Suppose we have a grid of equidistant points

$$x_n = n\Delta x, \quad n = 0, 1, 2, \ldots, 2N-1, \quad \Delta x = \frac{L}{2N}$$

The solution is known at each of these grid points $\{y(x_n)\}$. First the discrete Fourier transform is taken:

$$Y_k = \frac{1}{2N}\sum_{n=0}^{2N-1} y(x_n)e^{-2ik\pi x_n/L} \qquad k = -N, -N+1, \ldots, 0, \ldots, N-1, N$$

The inverse transformation is

$$y(x) = \frac{1}{L}\sum_{k=-N}^{N} Y_k e^{2ik\pi x/L}$$

Differentiate this to get

$$\frac{dy}{dx} = \frac{1}{L}\sum_{k=-N}^{N} Y_k \frac{2\pi ik}{L} e^{2ik\pi x/L}$$

Thus at the grid points

$$\left.\frac{dy}{dx}\right|_n = \sum_{k=-N}^{N} Y_k \frac{2\pi ik}{L} e^{2ik\pi x_n/L}$$

The process works as follows. From the solution at all grid points the Fourier transform is obtained by using the fast Fourier transform (FFT), $\{Y_k\}$. Then this is multiplied by $2\pi ik/L$ to obtain the Fourier transform of the derivative.

$$Y_k' = Y_k \frac{2\pi ik}{L}$$

Then the inverse Fourier transform is taken using FFT, giving the value of the derivative at each of the grid points.

$$\left.\frac{dy}{dx}\right|_n = \frac{1}{L}\sum_{k=-N}^{N} Y_k' e^{2ik\pi x_n/L}$$

The spectral method is used for direct numerical simulation (DNS) of turbulence. The Fourier transform is taken of the differential equation, and the resulting equation is solved. Then the inverse transformation gives the solution. When there are nonlinear terms, as in turbulent flow, they are calculated at each node in physical space, and the Fourier transform is taken of the result. This technique is especially suited to time-dependent problems, and the major computational effort is in the fast Fourier transform.

## INTRODUCTION

Optimization is a key enabling tool for decision making in chemical engineering. It has evolved from a methodology of academic interest into a technology that continues to have a significant impact on engineering research and practice. Optimization algorithms form the core tools for (1) experimental design, parameter estimation, model development, and statistical analysis; (2) process synthesis analysis, design, and retrofit; (3) model predictive control and real-time optimization; and (4) planning, scheduling, and the integration of process operations into the supply chain.

As shown in Fig. 3-53, optimization problems that arise in chemical engineering can be classified in terms of continuous and discrete variables. For the former, nonlinear programming (NLP) problems form the most general case, and widely applied specializations include linear programming (LP) and quadratic programming (QP). An important distinction for NLP is whether the optimization problem is convex or nonconvex. The latter NLP problem may have multiple local optima, and an important question is whether a global solution is required for the NLP. Another important distinction is whether the problem is assumed to be differentiable or not.

Mixed integer problems also include discrete variables. These can be written as mixed integer nonlinear programs (MINLPs), or as mixed integer linear programs (MILP), if all variables appear linearly in the constraint and objective functions. For the latter an important case occurs when all the variables are integer; this gives rise to an integer programming (IP) problem. IP problems can be further classified into many special problems (e.g., assignment, traveling salesperson, etc.), which are not shown in Fig. 3-53. Similarly, the MINLP problem also gives rise to special problem classes, although here the main distinction is whether its relaxation is convex or nonconvex.

The ingredients of formulating optimization problems include a mathematical model of the system, an objective function that quantifies a criterion to be extremized, variables that can serve as decisions, and, optionally, inequality constraints on the system. When represented in algebraic form, the general formulation of discrete and continuous optimization problems can be written as the following mixed integer optimization problem:

$$\text{Min } f(x,y) \quad \text{subject to} \quad h(x,y) = 0 \;\; g(x,y) \le 0 \;\; x \in \Re^n \;\; y \in \{0,1\}^t \qquad (3\text{-}70)$$

where $f(x, y)$ is the objective function (e.g., cost, energy consumption, etc.), $h(x, y) = 0$ are the equations that describe the performance of the system (e.g., material balances, production rates), and the inequality constraints $g(x, y) \le 0$ may define process specifications or constraints for feasible plans and schedules. Note that the operator max $f(x, y)$ is equivalent to Min$[-f(x, y)]$. We define the real $n$ vector $x$ to represent the continuous variables while the $t$ vector $y$ represents the discrete variables, which, without loss of generality, are often restricted to take values of 0 or 1 to define logical or discrete decisions, such as assignment of equipment and sequencing of tasks. (These variables can also be formulated to take on other integer values as well.) Problem (3-70) corresponds to a mixed integer nonlinear program

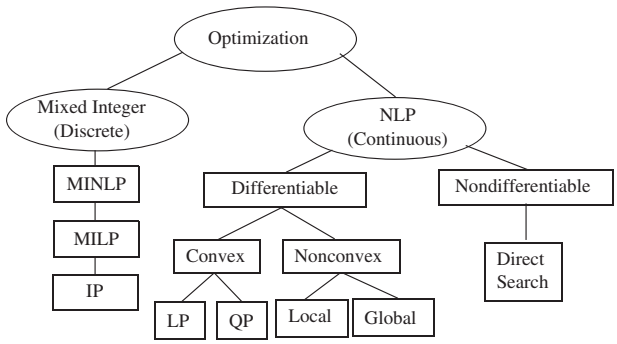

**FIG. 3-53** Classes of optimization problems and algorithms.

when any of the functions involved are nonlinear. If all functions are linear, it corresponds to a mixed integer linear program (3-89). If there are no 0–1 variables, then problem (3-70) reduces to a nonlinear program (3-71) or linear program (3-78) depending on whether the functions are linear.

Following the road map in Fig. 3-53, we start with continuous variable optimization and consider in the next section the solution of NLP problems with differentiable objective and constraint functions. If only local solutions are required for the NLP problem, then very efficient large-scale methods can be considered. This is followed by methods that are not based on local optimality criteria; we consider direct search optimization methods that do not require derivatives as well as deterministic global optimization methods. Following this, we consider the solution of mixed integer problems and outline the main characteristics of algorithms for their solution. Finally, we conclude with a discussion of optimization modeling software and its implementation on engineering models.

## GRADIENT-BASED NONLINEAR PROGRAMMING

For continuous variable optimization, we consider Eq. (3-70) without discrete variable $y$. The general NLP problem (3-71) is presented here:

$$\text{Min } f(x) \quad \text{subject to} \quad h(x) = 0, g(x) \le 0 \tag{3-71}$$

and we assume that the functions $f(x)$, $h(x)$, and $g(x)$ have continuous first and second derivatives. A key characteristic of Eq. (3-71) is whether the problem is convex or not, i.e., whether it has a convex objective function and a convex feasible region. A function $\phi(x)$ of $x$ in some domain $X$ is convex if and only if, for all points $x_1, x_2 \in X$,

$$\phi[\alpha x_1 + (1-\alpha)x_2] \le \alpha\phi[x_1 + (1-\alpha)x_2] + (1-\alpha)\phi(x_2) \tag{3-72}$$

holds for all $\alpha \in (0, 1)$. [Strict convexity requires that the inequality Eq. (3-72) be strict.] Convex feasible regions require $g(x)$ to be a convex function and $h(x)$ to be linear. Referring to Fig. 3-53, problem (3-71) is convex if and only if $f(x)$ and $g(x)$ are convex functions and $h(x)$ is a linear function. Otherwise, the problem is nonconvex. If Eq. (3-71) is a convex problem, then any local solution is guaranteed to be a global solution to Eq. (3-71). Moreover, if the objective function is strictly convex, then this solution $x^*$ is unique. On the other hand, nonconvex problems may have multiple local solutions, i.e., feasible solutions $x^*$ only within some nonvanishing neighborhood.

We first consider methods that find only local solutions to nonconvex problems, as more difficult (and expensive) search procedures are required to find a global solution. Local methods are currently very efficient and have been developed to deal with very large NLP problems. Moreover, by considering the structure of convex NLP problems (including LP and QP problems), even more powerful methods can be applied. To study these methods, we first consider conditions for local optimality.

**Local Optimality Conditions: A Kinematic Interpretation** Instead of a formal development of conditions that define a local optimum, we present a more intuitive kinematic illustration. Consider the contour plot of the objective function $f(x)$, given in Fig. 3-54, as a smooth valley in space of variables $x_1$ and $x_2$. For the contour plot of this unconstrained problem, Min $f(x)$, consider a ball rolling in this valley to the lowest point of $f(x)$, denoted by $x^*$. This point is at least a local minimum and is defined by a point with a zero gradient and at least nonnegative curvature in all (nonzero) directions $p$. We use the first-derivative (*gradient*) vector $\nabla f(x)$ and second-derivative (*hessian*) matrix $\nabla_{xx} f(x)$ to state the necessary first- and second-order conditions for unconstrained optimality:

$$\nabla_x f(x^*) = 0 \quad p^T \nabla_{xx} f(x^*) p \ge 0 \quad \text{for all } p \ne 0 \tag{3-73}$$

These necessary conditions for local optimality can be strengthened to sufficient conditions by making the inequality in Eq. (3-73) strict (i.e., positive curvature in all directions). Equivalently, the sufficient (necessary) curvature conditions can be stated as follows: $\nabla_{xx} f(x^*)$ has all positive (nonnegative) eigenvalues and is therefore defined as a positive (semidefinite) definite matrix.

Now consider the imposition of inequality $g(x) \le 0$ and equality constraints $h(x) = 0$ in Fig. 3-55. Continuing the kinematic interpretation, the inequality constraints $g(x) \le 0$ act as "fences" in the valley, and equality constraints $h(x) = 0$ act as "rails." Consider now a ball, constrained on a rail and within fences, to roll to its lowest point. This stationary point occurs when the normal forces exerted by the fences $[-\nabla g(x^*)]$ and rails $[-\nabla h(x^*)]$ on the ball are balanced by the force of gravity $[-\nabla f(x^*)]$. This condition can be stated by the following *Karush-Kuhn-Tucker (KKT) necessary conditions* for constrained optimality.

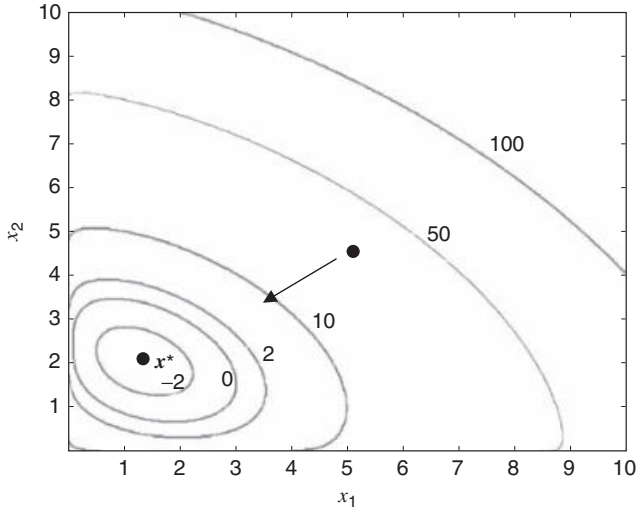

**FIG. 3-54** Unconstrained minimum.

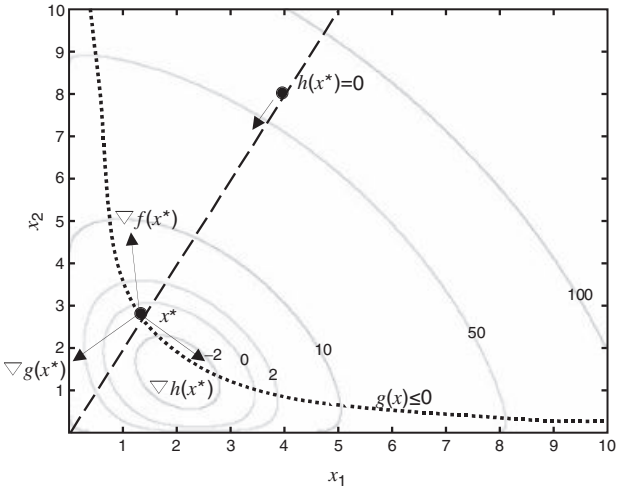

**FIG. 3-55** Constrained minimum.

***Balance of Forces*** It is convenient to define the Lagrange function $L(x, \lambda, \nu) = f(x) + g(x)^T\lambda + h(x)^T\nu$, along with "weights" or multipliers $\lambda$ and $\nu$ for the constraints. The stationarity condition (balance of forces acting on the ball) is then given by

$$\nabla L(x, \lambda, \nu) = \nabla f(x) + \nabla h(x)\,\lambda + \nabla g(x)\,\nu = 0 \tag{3-74}$$

***Feasibility*** Both inequality and equality constraints must be satisfied (the ball must lie on the rail and within the fences):

$$h(x) = 0 \qquad g(x) \le 0 \tag{3-75}$$

***Complementarity*** Inequality constraints are either strictly satisfied (active) or inactive, in which case they are irrelevant to the solution. In the latter case the corresponding KKT multiplier must be zero. This is written as

$$\nu^T g(x) = 0 \qquad \nu \ge 0 \tag{3-76}$$

***Constraint Qualification*** For a local optimum to satisfy the KKT conditions, an additional regularity condition is required on the constraints. This can be defined in several ways. A typical condition is

that the active constraints at $x^*$ be linearly independent; i.e., the matrix $[\nabla h(x^*)|\nabla g_A(x^*)]$ is full column rank, where $g_A$ is the vector of inequality constraints with elements that satisfy $g_{Ai}(x^*) = 0$. With this constraint qualification, the KKT multipliers ($\lambda$, $\nu$) are guaranteed to be unique at the optimal solution.

***Second-Order Conditions*** As with unconstrained optimization, nonnegative (positive) curvature is necessary (sufficient) in all the allowable (i.e., constrained) nonzero directions $p$. The necessary second-order conditions can be stated as

$$p^T \nabla_{xx} L(x^*) p \geq 0$$

$$\text{for all } p \neq 0 \text{ with } \nabla h(x^*)^T p = 0,\ \nabla g_A(x^*)^T p \leq 0,\ \nabla g_{Ai}(x^*)^T p = 0 \text{ for } \nu_i > 0 \qquad (3\text{-}77)$$

and the corresponding sufficient conditions require the first inequality in Eq. (3-77) to be strict. Note that in Fig. 3-54, the allowable directions $p$ span the entire space for $x$ while in Fig. 3-55 there are *no* allowable directions $p$.

**Convex Cases of NLP Problems** Linear programs and quadratic programs are special cases of Eq. (3-71) that allow for more efficient solution, based on application of KKT conditions Eq. (3-74) through Eq. (3-77). Because these are convex problems, any locally optimal solution is a global solution. In particular, if the objective and constraint functions in Eq. (3-71) are linear, then the following linear program (LP)

$$\text{Min } c^T x \quad \text{subject to} \quad Ax = b \text{ and } Cx \leq d \qquad (3\text{-}78)$$

can be solved in a finite number of steps, and the optimal solution lies at a vertex of the polyhedron described by the linear constraints. This is shown in Fig. 3-56, and in so-called primal degenerate cases, multiple vertices can be alternate optimal solutions, with the same values of the objective function. The standard method to solve Eq. (3-78) is the simplex method, developed in the late 1940s, although since Karmarkar's discovery in 1984 interior point methods have also become quite advanced and competitive for highly constrained problems. The simplex method proceeds by moving successively from vertex to vertex with improved objective function values. Methods to solve Eq. (3-78) are well implemented and widely used, especially in planning and logistical applications. They also form the basis for MILP methods discussed later. Currently, state-of-the-art LP solvers can handle millions of variables and constraints, and the application of further decomposition methods leads to the solution of problems that are two or three orders of magnitude larger than this. See the general references of Hillier and Lieberman (2015) and Nocedal and Wright (2006) for more details. Also, the interior point method is described below from the perspective of more general NLP problems.

Quadratic programs (QPs) represent a slight modification of Eq. (3-78) and can be stated as

$$\text{Min } c^T x + 1/2\, x^T Q x \quad \text{subject to} \quad Ax = b \quad Cx \leq d \qquad (3\text{-}79)$$

If the matrix $Q$ is positive semidefinite (positive definite) when projected into the null space of the active constraints, then Eq. (3-79) is (strictly) convex and the QP is a global (and unique) minimum. Otherwise, local solutions may exist for Eq. (3-79), and more extensive global optimization methods are needed to obtain the global solution. Like LPs, convex QPs can be solved in a finite number of steps. However, as seen in Fig. 3-57, these optimal solutions may lie on a vertex, on a constraint boundary, or in the interior. A number of active set strategies have been created that solve the KKT conditions of the QP and incorporate efficient updates of active constraints. Popular methods include null space algorithms, range space methods, and Schur complement methods. As with LPs, QP problems can also be solved with interior point methods.

**Solving the General NLP Problem** Solution techniques for Eq. (3-71) deal with satisfaction of the KKT conditions, Eq. (3-74) through Eq. (3-77). Many NLP solvers are based on successive quadratic programming (SQP) as it allows the construction of a number of NLP algorithms based on the Newton-Raphson method for equation solving (see the Numerical Analysis section). SQP solvers have been shown to require the fewest function evaluations to solve NLP problems, and they can be tailored to a broad range of process engineering problems with different structure.

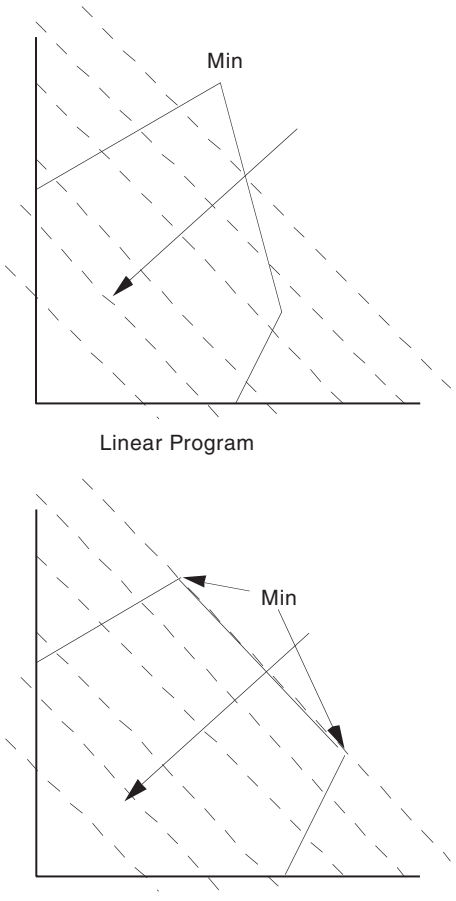

**FIG. 3-56** Contour plots of linear programs.

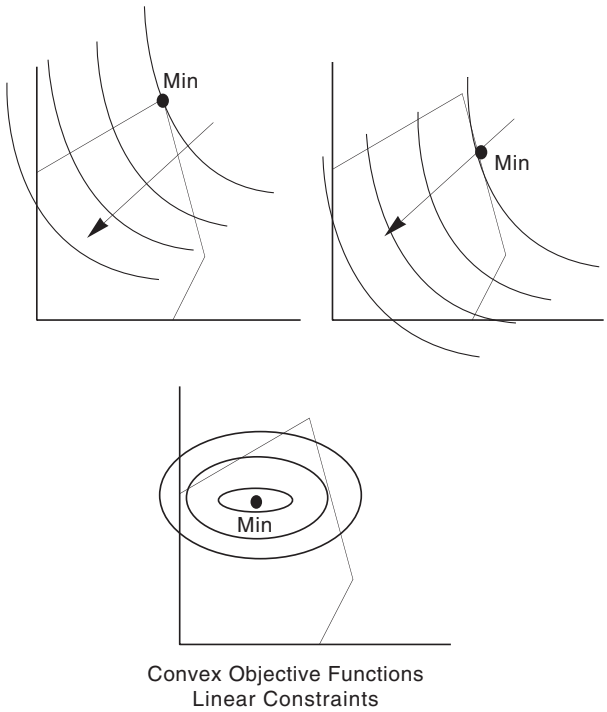

**FIG. 3-57** Contour plots of convex quadratic programs.

The SQP strategy applies the equivalent of a Newton step to the KKT conditions of the nonlinear programming problem, and this leads to a fast rate of convergence. By adding slack variables $s$, the first-order KKT conditions can be rewritten as

$$\nabla f(x) + \nabla h(x)\,\lambda + \nabla g(x)\,\nu = 0 \quad (3\text{-}80a)$$
$$h(x) = 0 \quad (3\text{-}80b)$$
$$g(x) + s = 0 \quad (3\text{-}80c)$$
$$SVe = 0 \quad (3\text{-}80d)$$
$$(s, \nu) \geq 0 \quad (3\text{-}80e)$$

where $e = [1, 1, \ldots, 1]^T$, $S = \text{diag}\{s\}$, and $V = \text{diag}\{\nu\}$. SQP methods find solutions that satisfy Eq. (3-80) by generating Newton-like search directions at iteration $k$. However, Eq. (3-80$d$) and active bounds Eq. (3-80$e$) are dependent at the solution and serve to make the KKT system ill conditioned near the solution. SQP algorithms treat these conditions in two ways. In the *active set strategy*, discrete decisions are made regarding the active constraint set $i \in I = \{i \mid g_i(x^*) = 0\}$, and Eq. (3-80$d$) is replaced by $s_i = 0$, $i \in I$, and $\nu_i = 0$, $i \notin I$. Determining the active set is a combinatorial problem, and a straightforward way to determine an estimate of the active set [and to satisfy Eq. (3-80$e$)] is to formulate and solve, at a point $x^k$, the following QP at iteration $k$:

$$\text{Min } \nabla f(x^k)^T p + 1/2\, p^T \nabla_{xx} L(x^k, \lambda^k, \nu^k) p$$
$$\text{subject to: } h(x^k) + \nabla h(x^k)^T p = 0 \quad g(x^k) + \nabla g(x^k)^T p + s = 0 \quad s \geq 0 \quad (3\text{-}81)$$

The KKT conditions of Eq. (3-81) are given by

$$\nabla f(x^k) + \nabla^2 L(x^k, \lambda^k, \nu^k) p + \nabla h(x^k)\,\lambda + \nabla g(x^k)\,\nu = 0 \quad (3\text{-}82a)$$
$$h(x^k) + \nabla h(x^k)^T p = 0 \quad (3\text{-}82b)$$
$$g(x^k) + \nabla g(x^k)^T p + s = 0 \quad (3\text{-}82c)$$
$$SVe = 0 \quad (3\text{-}82d)$$
$$(s, \nu) \geq 0 \quad (3\text{-}82e)$$

where the hessian of the Lagrange function $\nabla_{xx} L(x, \lambda, \nu) = \nabla_{xx}[f(x) + h(x)^T\lambda + g(x)^T\nu]$ is calculated directly or through a quasi-Newton approximation (created by differences of gradient vectors). If Eq. (3-81) is strictly convex, it is easy to show that Eqs. (3-82$a$) through (3-82$c$) correspond to a Newton-Raphson step for Eqs. (3-80$a$) through (3-80$c$) applied at iteration $k$. Also, selection of the active set is now handled at the QP level by satisfying the conditions of Eqs. (3-82$d$) and (3-82$e$). To evaluate and change candidate active sets, QP algorithms apply inexpensive matrix updating strategies to the KKT matrix associated with Eq. (3-82). Details of this approach can be found in Nocedal and Wright (2006).

As alternatives that avoid the combinatorial problem of selecting the active set, interior point (or barrier) methods modify the NLP problem Eq. (3-71) to form

$$\text{Min } f(x^k) - \mu \Sigma_i \ln s_i \quad \text{subject to} \quad h(x^k) = 0 \quad g(x^k) + s = 0 \quad (3\text{-}83)$$

where the solution to Eq. (3-84) has $s > 0$ for the penalty parameter $\mu > 0$. Decreasing $\mu$ to 0 leads to solution of problem Eq. (3-71). The KKT conditions for this problem can be written as

$$\begin{aligned} &\nabla f(x^*) + \nabla h(x^*)\,\lambda + \nabla g(x^*)\,\nu = 0 \\ &h(x^*) = 0 \\ &g(x^*) + s = 0 \\ &SVe = \mu e \end{aligned} \quad (3\text{-}84)$$

and for $\mu > 0$, $s > 0$, and $\nu > 0$, Newton steps generated to solve Eqs. (3-84) are well behaved and analogous to Eq. (3-82), with a modification on the right-hand side of Eq. (3-82$d$). A detailed description of a particular interior point algorithm, called IPOPT, can be found in Wächter and Biegler [*Math. Prog.* **106**(1): 25–57 (2006)].

Both active set and interior point methods possess clear trade-offs. Interior point methods may require more iterations to solve Eqs. (3-84) for various values of $\mu$, while active set methods require the solution of the more expensive QP subproblem Eq. (3-81). Thus, if there are few inequality constraints or an active set is known (say from a good starting guess, or a known QP solution from a previous iteration), then solving Eq. (3-81) is not expensive and the active set method is favored. However, for problems with many inequality constraints, interior point methods are often faster, as they avoid the combinatorial problem of selecting the active set. This is especially true for large-scale problems where a large number of bounds are active. Examples that demonstrate the application of these approaches include the solution of model predictive control (MPC) problems and the solution of large optimal control problems using barrier NLP solvers. For instance, IPOPT allows the solution of problems with more than 1,000,000 variables and up to 50,000 degrees of freedom [see Biegler et al., *Chem. Eng. Sci.* **57**(4): 575–593 (2002); Laird et al., *ASCE J. Water Resource Management and Planning* **131**(2):125 (2005)].

**Other Gradient-Based NLP Solvers** In addition to SQP methods, a number of NLP solvers have been developed and adapted for large-scale problems. Generally these methods require more function evaluations than for SQP methods, but they perform very well when interfaced to optimization modeling platforms, where function evaluations are cheap. All these can be derived from the perspective of applying Newton steps to portions of the KKT conditions.

LANCELOT (Conn et al., 2000) is based on the solution of bound-constrained subproblems. Here an augmented lagrangian is formed from Eq. (3-71), and the following subproblem is solved:

$$\text{Min } f(x) + \lambda^T h(x) + \nu^T[g(x) + s] + 1/2\,\rho \|h(x), g(x) + s\|^2 \quad \text{subject to} \quad s \geq 0 \quad (3\text{-}85)$$

The above subproblem can be solved very efficiently for fixed values of the multipliers $\lambda$ and $\nu$ and penalty parameter $\rho$. Here a gradient projection trust region method is applied. Once subproblem Eq. (3-85) is solved, the multipliers and penalty parameter are updated in an outer loop, and the cycle repeats until the KKT conditions for Eq. (3-71) are satisfied. LANCELOT works best when exact second derivatives are available. This promotes a fast convergence rate in solving each subproblem and allows a bound-constrained trust region method to exploit directions of negative curvature in the hessian matrix.

*Reduced gradient methods* are active set strategies that rely on partitioning the variables and solving Eq. (3-80) in a nested manner. Without loss of generality, problem Eq. (3-71) can be rewritten as Min $f(z)$ subject to $c(z) = 0$ and $a \leq z \leq b$. Variables are partitioned as nonbasic variables (those fixed to their bounds), basic variables (those that can be solved from the equality constraints), and superbasic variables (those remaining variables between bounds that serve to drive the optimization); this leads to $z^T = [z_N{}^T, z_B{}^T, z_S{}^T]$. This partition is derived from local information and may change over the course of the optimization iterations. The corresponding KKT conditions can be written as

$$\nabla_N f(z) + \nabla_N c(z)\gamma = \beta_a - \beta_b \quad (3\text{-}86a)$$
$$\nabla_B f(z) + \nabla_B c(z)\gamma = 0 \quad (3\text{-}86b)$$
$$\nabla_S f(z) + \nabla_S c(z)\gamma = 0 \quad (3\text{-}86c)$$
$$c(z) = 0 \quad (3\text{-}86d)$$
$$z_{Nj} = a_j \text{ or } b_j \qquad \beta_{aj} \geq 0 \qquad \beta_{bj} = 0 \quad \text{or} \quad \beta_{bj} \geq 0 \quad \beta_{aj} = 0 \quad (3\text{-}86e)$$

where $\gamma$ and $\beta$ are the KKT multipliers for the equality and bound constraints, respectively, and Eq. (3-86$e$) replaces the complementarity conditions in Eq. (3-76). Reduced gradient methods work by nesting equations Eqs. (3-86$b$ and $d$) within Eqs. (3-86$a$ and $c$). At iteration $k$, for fixed values of $z_N{}^k$ and $z_S{}^k$, we can solve for $z_B$ by using Eq. (3-86$d$) and for $\gamma$ by using Eq. (3-86$b$). Moreover, linearization of these equations leads to sensitivity information (i.e., constrained derivatives or reduced gradients) that indicates how $z_B$ changes with respect to $z_S$ and $z_N$. The algorithm then proceeds by updating $z_S$ by using reduced gradients derived from Eq. (3-86$b$) and given by

$$df(z)/dz_S = \nabla_S f(z) + \nabla_S c(z)\,\gamma = \nabla_S f(z) - \nabla_S c(z)\,\nabla_B c(z)^{-1}\nabla_B f(z) \quad (3\text{-}87)$$

Driving $df/dz_S$ to zero, with quasi-Newton or Newton iterations, solves Eq. (3-86$c$). Following this, bound multipliers $\beta$ are calculated from Eq. (3-86$a$). Over the course of the iterations, if the variable $z_B$ or $z_S$ exceeds its bounds or if some bound multipliers $\beta$ become negative, then the variable partition needs to be changed and Eqs. (3-86) are reconstructed. These reduced gradient methods are embodied in the popular GRG2, CONOPT, and SOLVER codes (Edgar et al., 2002). The SOLVER code has been incorporated into Microsoft Excel.

**Algorithmic Details for NLP Methods** All the above NLP methods incorporate concepts from the Newton-Raphson method for equation solving. Essential features of these methods are that they provide (1) accurate derivative information to solve for the KKT conditions, (2) stabilization strategies to promote convergence of the Newton-like method from poor starting points, and (3) regularization of the jacobian matrix in Newton's method (the so-called KKT matrix) if it becomes singular or ill conditioned.

1. *NLP methods that use first and second derivatives.* The KKT conditions require first derivatives to define stationary points, so accurate first derivatives are essential to determine locally optimal solutions for differentiable NLPs. Moreover, Newton-Raphson methods that are applied to the KKT conditions, as well as the task of checking second-order KKT conditions, necessarily require second-derivative information. (Note that second-order conditions are not checked by methods that do not use second derivatives.) With the recent development of automatic differentiation tools, many modeling and simulation platforms can provide exact first and second derivatives for optimization. When second derivatives are available for the objective or constraint functions, they can be used directly in LANCELOT as well as SQP and reduced gradient methods. Otherwise, on problems with few superbasic variables, both reduced gradient methods and SQP methods [with reduced gradient methods applied to the QP subproblem Eq. (3-81)] can benefit from positive definite quasi-Newton approximations (Nocedal and Wright, 2006) applied to reduced second-derivative quantities (the so-called reduced hessian). Finally, for problems with least squares functions (see Statistics subsection), as in data reconciliation, parameter estimation, and model predictive control, one often assumes that the values of the objective function and its gradient at the solution are vanishingly small. Under these conditions, one can show that the multipliers $(\lambda, \nu)$ also vanish and $\nabla_{xx}L(x, \lambda, \nu)$ can be substituted by $\nabla_{xx}f(x^*)$. This *Gauss-Newton approximation* has been shown to be very efficient for the solution of least squares problems (see Nocedal and Wright, 2006).

2. *Line search and trust region methods promote convergence from poor starting points.* These are commonly used with the search directions calculated from NLP subproblems such as Eq. (3-81). In a *trust region approach*, the constraint $||p|| \le \Delta$ is added, and the iteration step is taken if there is sufficient reduction of some merit function (e.g., the objective function weighted with some measure of the constraint violations). The size of the trust region $\Delta$ is adjusted based on the agreement of the reduction of the actual merit function compared to its predicted reduction from the subproblem (see Conn et al., 2000). Such methods have strong global convergence properties and are especially appropriate for ill-conditioned NLPs. This approach has been applied in the KNITRO code (see Nocedal and Wright, 2006). *Line search methods* can be more efficient on problems with reasonably good starting points and well-conditioned subproblems, as in real-time optimization. Typically, once a search direction is calculated from Eq. (3-81), or other related subproblem, a step size $\alpha \in (0, 1)$ is chosen so that $x^k + \alpha p$ leads to a sufficient decrease of a merit function. As a recent alternative, a novel *filter* stabilization strategy (for both line search and trust region approaches) has been developed based on a bicriterion minimization, with the objective function and constraint infeasibility as competing objectives [Fletcher et al., *SIAM J. Optim.* **13**(3):635 (2002)]. This method often leads to better performance than that based on merit functions.

3. *Regularization of the KKT matrix for the NLP subproblem is essential for good performance of general-purpose algorithms.* For instance, to obtain a unique solution to Eq. (3-81), active constraint gradients must be full rank and the hessian matrix, when projected into the null space of the active constraint gradients, must be positive definite. These properties may not hold far from the solution, and corrections to the hessian in SQP may be necessary. Regularization methods ensure that subproblems such as Eq. (3-81) remain well conditioned; they include addition of positive constants to the diagonal of the hessian matrix to ensure its positive definiteness, judicious selection of active constraint gradients to ensure that they are linearly independent, and scaling the subproblem to reduce the propagation of numerical errors. Often these strategies are heuristics built into particular NLP codes. While quite effective, most of these heuristics do not provide convergence guarantees for general NLPs.

From the conceptual descriptions as well as algorithmic details given above, it is clear that NLP solvers are complex algorithms that have required considerable research and development to turn them into reliable and efficient software tools. Practitioners who are confronted with engineering optimization problems should therefore leverage these efforts, rather than write their own codes. Table 3-3 presents a sampling of available NLP codes that represent the above classifications.

**TABLE 3-3 Representative NLP Solvers**

| Method | Algorithm type | Stabilization | Second-order information |
|---|---|---|---|
| CONOPT (Drud, 1994) | Reduced gradient | Line search | Exact and quasi-Newton |
| GRG2 (Edgar et al., 2002) | Reduced gradient | Line search | Quasi-Newton |
| IPOPT | SQP, barrier | Line search | Exact |
| KNITRO (Byrd et al., 1997) | SQP, barrier | Trust region | Exact and quasi-Newton |
| LANCELOT | Augmented Lagrangian, bound constrained | Trust region | Exact and quasi-Newton |
| LOQO | SQP, barrier | Line search | Exact |
| MINOS | Reduced gradient, augmented Lagrangian | Line search | Quasi-Newton |
| NPSOL | SQP, active set | Line search | Quasi-Newton |
| SNOPT | Reduced space SQP, active set | Line search | Quasi-Newton |
| SOCS | SQP, active set | Line search | Exact |
| SOLVER | Reduced gradient | Line search | Quasi-Newton |
| SRQP | Reduced space SQP, active set | Line search | Quasi-Newton |

## OPTIMIZATION METHODS WITHOUT DERIVATIVES

A broad class of optimization strategies does not require derivative information. These methods have the advantage of easy implementation and little prior knowledge of the optimization problem. In particular, such methods are well suited for "quick and dirty" optimization studies that explore the scope of optimization for new problems, prior to investing effort for more sophisticated modeling and solution strategies. Most of these methods are derived from heuristics that naturally spawn numerous variations. As a result, a very broad literature describes these methods. Here we discuss only a few important trends in this area.

**Classical Direct Search Methods** Developed in the 1960s and 1970s, these methods include one-at-a-time search and methods based on experimental designs (EVOP). At that time, direct search methods were the most popular optimization methods in chemical engineering. Methods that fall into this class include the pattern search of Hooke and Jeeves [*J. ACM* **8:** 212 (1961)], the conjugate direction method of Powell (1964), the simplex search of Nelder-Mead [*Comput. J.* **7:** 308 (1965)], and the adaptive random search methods of Luus-Jaakola [*AIChE J.* **19:** 760 (1973)], Goulcher and Cesares Long [*Comp. Chem. Engr.* **2:** 23 (1978)], and Banga et al. [in *State of the Art in Global Optimization*, C. Floudas and P. Pardalos, eds., Kluwer, Dordrecht, 1996, p. 563]. All these methods require only objective function values for unconstrained minimization. Associated with these methods are numerous studies on a wide range of process problems. Moreover, many of these methods include heuristics that prevent premature termination (e.g., directional flexibility in the complex search as well as random restarts and direction generation).

**Simulated Annealing** This strategy is related to random search methods and derives from a class of heuristics with analogies to the motion of molecules in the cooling and solidification of metals (Laarhoven and Aarts, *Simulated Annealing: Theory and Applications*, Reidel Publishing, Dordrecht, 1987). Here a temperature parameter $\theta$ can be raised or lowered to influence the probability of accepting points that do not improve the objective function. The method starts with a base point $x$ and objective value $f(x)$. The next point $x'$ is chosen at random from a distribution. If $f(x') < f(x)$, the move is accepted with $x'$ as the new point. Otherwise, $x'$ is accepted with probability $p(\theta, x', x)$. Options include the Metropolis distribution $p(\theta, x, x') = \exp\{-[f(x') - f(x)]/\theta\}$ and the Glauber distribution, $p(\theta, x, x') = \exp\{-[f(x') - f(x)]/\theta\}/(1 + \exp\{-[f(x') - f(x)]/\theta\})$. The $\theta$ parameter is then reduced, and the method continues until no further progress is made.

**Genetic Algorithms** This approach, described in Holland, J. H., *Adaptations in Natural and Artificial Systems* (University of Michigan Press, Ann Arbor, 1975), is based on the analogy of improving a population of solutions through modifying their gene pool. It also has similar performance characteristics as random search methods and simulated annealing. Two forms of genetic modification, crossover or mutation, are used, and the elements of the optimization vector $x$ are represented as binary strings. Crossover deals with random swapping of vector elements (among parents with highest objective function values or other rankings of population) or any linear combinations of two parents. Mutation deals

with the addition of a random variable to elements of the vector. Genetic algorithms (GAs) have seen widespread use in process engineering, and a number of codes are available. Edgar et al. (2002) describe a related GA that is available in MS Excel.

**Derivative-Free Optimization (DFO)** Over the past two decades, the availability of parallel computers and faster computing hardware and the need to incorporate complex simulation models within optimization studies have led a number of optimization researchers to reconsider classical direct search approaches. In particular, Dennis and Torczon [*SIAM J. Optim.* **1:** 448 (1991)] developed a multidimensional search algorithm that extends the simplex approach of Nelder and Mead (1965). They note that the Nelder-Mead algorithm fails as the number of variables increases, even for very simple problems. To overcome this, their multidimensional pattern search approach combines reflection, expansion, and contraction steps that act as line search algorithms for a number of linearly independent search directions. This approach is easily adapted to parallel computation, and the method can be tailored to the number of processors available. Moreover, this approach converges to locally optimal solutions for unconstrained problems and observes an unexpected performance synergy when multiple processors are used. The work of Dennis and Torczon (1991) has spawned considerable research on the analysis and code development for DFO methods. In addition, Conn et al. (*Introduction to Derivative Free Optimization*, SIAM, Philadelphia, Penn., 2009) constructed a multivariable DFO algorithm that uses a surrogate model for the objective function within a trust region method. Here points are sampled to obtain a well-defined quadratic interpolation model, and descent conditions from trust region methods enforce convergence properties. A comprehensive overview and convergence analysis of pattern search, surrogate, and trust region DFO methods is presented in Conn, Scheinberg, and Vicente (2009). Moreover, several DFO codes have been developed that lead to black box optimization implementations for large, complex simulation models [see Audet and Dennis, *SIAM J. Optim.* **13:** 889 (2003); Kolda et al., *SIAM Rev.* **45**(3): 385 (2003)].

Direct search methods are easy to apply to a wide variety of problem types and optimization models. Moreover, because their termination criteria are not based on gradient information and stationary points, they are more likely to favor the search for globally optimal rather than locally optimal solutions. These methods can also be adapted easily to include integer variables. However, no rigorous convergence properties to globally optimal solutions have yet been discovered. Also, these methods are best suited for unconstrained problems or for problems with simple bounds. Otherwise, they may have difficulties with constraints, as the only options open for handling constraints are equality constraint elimination and addition of penalty functions for inequality constraints. Both approaches can be unreliable and may lead to failure of the optimization algorithm. Finally, the performance of direct search methods scales poorly (and often exponentially) with the number of decision variables. While performance can be improved with the use of parallel computing, these methods are rarely applied to problems with more than a few dozen decision variables.

## GLOBAL OPTIMIZATION

Deterministic optimization methods are available for nonconvex nonlinear programming problems of the form of Eq. (3-71) that guarantee convergence to the global optimum. More specifically, one can show under mild conditions that they converge to an $\varepsilon$ distance to the global optimum in a finite number of steps. These methods are generally more expensive than local NLP methods, and they require the exploitation of the structure of the nonlinear program.

Because global optima cannot be characterized by properties analogous to KKT conditions for local optima, global optimization methods work by partitioning the problem domain (i.e., containing the feasible region) into subregions. Upper bounds on the objective function are computed over all subregions of the problem. In addition, lower bounds can be derived from convex relaxations of the objective function and constraints for each subregion. The algorithm then proceeds to eliminate all subregions that have infeasible constraint relaxations or lower bounds that are greater than the least upper bound. After this, the remaining regions are further partitioned to create new subregions, and the cycle continues until the upper and lower bounds converge.

This basic concept leads to a wide variety of global algorithms, with the following features that can exploit different problem classes. *Bounding* strategies relate to the calculation of upper and lower bounds. For the former, any feasible point or, preferably, a locally optimal point in the subregion can be used. For the lower bound, convex relaxations of the objective and constraint functions are derived. The *refining* step deals with the construction of partitions in the domain and further partitioning them during the search process. Finally, the *selection* step decides on the order of exploring the open subregions.

For simplicity, consider the problem Min $f(x)$ subject to $g(x) \le 0$ where each function can be defined by additive terms. Convex relaxations for $f(x)$ and $g(x)$ can be derived in the following ways:

- Convex additive terms remain unmodified in these functions.
- Concave additive unary terms are replaced by linear underestimating functions that match the terms at the boundaries of their subregions.
- Nonconvex polynomial terms can be replaced by a set of scalar bilinear terms, with new variables introduced to define the higher-order polynomials.
- The scalar bilinear terms can be relaxed by using the McCormick underestimator; e.g., the bilinear term $xz$ is replaced by a new variable $w$ and linear inequality constraints

$$\begin{aligned} w &\ge x_l z + z_l x - x_l z_l \\ w &\ge x_u z + z_u x - x_u z_u \\ w &\le x_u z + z_l x - x_u z_l \\ w &\le x_l z + z_u x - x_l z_u \end{aligned} \tag{3-88}$$

where the subregions are defined by $x_l \le x \le x_u$ and $z_l \le z \le z_u$. Thus the feasible region and the objective function are replaced by convex envelopes to form relaxed problems.

Solving these convex relaxed problems leads to global solutions that are lower bounds to the NLP in the particular subregion. Finally, we see that gradient-based NLP solvers play an important role in global optimization algorithms, as they often yield the lower and upper bounds for the subregions. The *spatial branch and bound* global optimization algorithm can therefore be given by the following steps:

0. *Initialize algorithm.* Calculate upper and lower bounds over the entire (relaxed) feasible region.

For iteration $k$ with a set of partitions $M_{kj}$ and bounds in each subregion $f_{Lj}$ and $f_{Uj}$:

1. *Bound.* Define the best upper bound $f_U = \mathrm{Min}_j f_{Uj}$ and delete ( fathom) all subregions $j$ with lower bounds $f_{Lj} \ge f_U$. If the remaining subregions satisfy $f_{Lj} \ge f_U - \varepsilon$, stop.

2. *Refine.* Divide the remaining active subregions into partitions $M_{kj1}$ and $M_{kj2}$. (Many branching rules are available for this step.)

3. *Select.* Solve the convex relaxed NLP in the new partitions to obtain $f_{Lj1}$ and $f_{Lj2}$. Delete the partition if there is no feasible solution.

4. *Update.* Obtain upper bounds $f_{Uj1}$ and $f_{Uj2}$ to new partitions, if present. Set $k = k + 1$, update partition sets, and go to step 1.

Note that a number of improvements can be made to the bounding, refinement, and selection strategies in the algorithm that accelerate the convergence of this method. A comprehensive discussion of all these options can be found in Floudas (2000) and Tawarlamani and Sahinidis (2002). Also, a number of efficient global optimization codes have recently been developed, including αBB, BARON, LGO, and OQNLP. An interesting numerical comparison of these and other codes can be found in Neumaier et al., *Math. Prog. B* **103**(2): 335 (2005).

## MIXED INTEGER PROGRAMMING

Mixed integer programming deals with both discrete and continuous decision variables. For this presentation we consider discrete decisions as binary variables, that is, $y_i = 0$ or 1, and we consider the mixed integer problem (3-70). Unlike in local optimization methods, there are no optimality conditions, such as the KKT conditions, that can be applied directly. Instead, as in global optimization methods, a systematic search of the solution space, coupled with upper and lower bounding information, is applied. As with global optimization problems, large mixed integer programs can be expensive to solve, and some care is needed in problem formulation.

**Mixed Integer Linear Programming** If the objective and constraint functions are all linear, then Eq. (3-70) becomes a mixed integer linear programming problem given by

$$\text{Min } a^T x + c^T y \quad \text{subject to} \quad Ax + By \le b \quad x \ge 0 \quad y \in \{0, 1\}^t \tag{3-89}$$

Note that if we relax the $t$ binary variables by the inequalities $0 \le y \le 1$, then Eq. (3-89) becomes a linear program with a (global) solution that is a lower bound to the MILP Eq. (3-89). There are specific MILP classes where the LP relaxation of Eq. (3-89) has the same solution as the MILP. Among these problems is the well-known *assignment problem.* Other MILPs that can be solved with efficient special-purpose methods are the *knapsack* problem, the *set covering* and *set partitioning* problems, and the *traveling salesperson* problem. See Nemhauser and Wolsey (1999) for a detailed treatment of these problems.

More generally, MILPs are solved with branch and bound algorithms, similar to the spatial branch and bound method of the previous section, that

explore the search space. As seen in Fig. 3-58, binary variables are used to define the search tree, and a number of bounding properties can be noted from the structure of Eq. (3-89).

Upper bounds on the objective function can be found from any feasible solution to Eq. (3-89), with $y$ set to integer values. These can be found at the bottom or "leaf" nodes of a branch and bound tree (and sometimes at intermediate nodes as well). The top, or root, node in the tree is the solution to the linear programming relaxation of Eq. (3-89); this is a lower bound to Eq. (3-89). On the other hand, as one proceeds down the tree with a partial assignment of the binary variables, a lower bound for any leaf node in that branch can be found from solution of the linear program at this intermediate node with the remaining binary variables relaxed. This leads to the following properties:

- Any intermediate node with an infeasible LP relaxation has infeasible leaf nodes and can be fathomed (i.e., all remaining children of this node can be eliminated).
- If the LP solution at an intermediate node is not less than an existing integer solution, then the node can be fathomed.

These properties lead to pruning of the search tree. Branching then continues in the tree until the upper and lower bounds converge.

This basic concept leads to a wide variety of MILP algorithms with the following features. *LP solutions* at intermediate nodes are relatively easy to calculate with the simplex method. If the solution of the parent node is known, multiplier information from this solution can be used to calculate (via efficient pivoting operations) the LP solution at the child node. *Branching strategies* to navigate the tree take a number of forms. More common *depth-first strategies* expand the most recent node to a leaf node or infeasible node and then backtrack to other branches in the tree. These strategies are simple to program and require little storage of past nodes. On the other hand, *breadth-first strategies* expand all the nodes at each level of the tree, select the node with the lowest objective function, and then proceed until the leaf nodes are reached. Here more storage is required, but generally fewer nodes are evaluated than in depth-first search. In addition, *selection of binary variable for branching* is based on a number of criteria, including choosing the variable with the relaxed value closest to 0 or 1, or the one leading to the largest change in the objective. A number of improved branching rules can accelerate the convergence of this method, and a number of efficient, large-scale MILP codes are widely used, including CPLEX, OSL, XPRESS, and ZOOM. Additional description of these strategies can be found in Nemhauser and Wolsey (1999).

***Example*** To illustrate the branch and bound approach, we consider the MILP:

$$\begin{aligned} \text{Min } & Z = x + y_1 + 2y_2 + 3y_3 \\ \text{subject to } & -x + 3y_1 + y_2 + 2y_3 \le 0 \\ & -4y_1 - 8y_2 - 3y_3 \le -10 \\ & x \ge 0, y_1, y_2, y_3 \in \{0,1\} \end{aligned}$$

The solution to this problem is given by $x = 4, y_1 = 1, y_2 = 1, y_3 = 0$, and $Z = 7$. Here we use a depth-first strategy and branch on the variables closest to 0 or 1. Figure 3-58 shows the progress of the branch and bound algorithm as the binary variables are selected and the bounds are updated. The sequence numbers for each node in Fig. 3-58 show the order in which they are processed. The grayed partitions correspond to the deleted nodes, and at termination of the algorithm we see that $Z = 7$ and an integer solution is obtained at an intermediate node where coincidentally $y_3 = 0$.

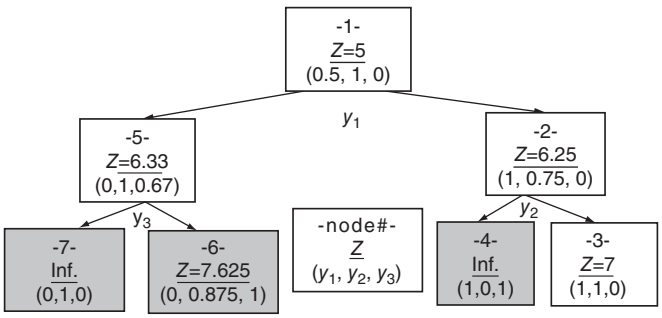

**FIG. 3-58** Branch and bound sequence for MILP example.

**Mixed Integer Nonlinear Programming** Without loss of generality, we can rewrite the MINLP in Eq. (3-71) as

$$\text{Min } f(x) + c^T y \quad \text{subject to} \quad g(x) + By \le b \quad x \ge 0 \quad y \in \{0,1\}^t \tag{3-90}$$

where the binary variables are kept as separate linear terms. MINLP strategies can be classified into two types. The first deals with nonlinear extensions of the branch and bound method discussed above for MILPs. The second deals with outer approximation decomposition strategies that provide lower and upper bounding information for convergence.

***Nonlinear Branch and Bound*** The MINLP Eq. (3-90) can be solved in a similar manner to Eq. (3-89). If the functions $f(x)$ and $g(x)$ in Eq. (3-90) are convex, then direct extensions to the branch and bound method can be made. A relaxed NLP can be solved at the root node, upper bounds to the solution of Eq. (3-90) can be found at the leaf nodes, and the bounding properties due to NLP solutions at intermediate nodes still hold. However, this approach is more expensive than the corresponding MILP method. First, NLPs are more expensive than LPs to solve. Second, unlike with relaxed LP solutions, NLP solutions at child nodes cannot be updated directly from solutions at parent nodes. Instead, the NLP needs to be solved again (but one hopes with a better starting guess). The NLP branch and bound method is used in the SBB code interfaced to GAMS. In addition, Leyffer [*Comput. Optim. Appl.* **18:** 295 (2001)] proposed a hybrid MINLP strategy nested within an SQP algorithm. At each iteration, a mixed integer quadratic program is formed, and a branch and bound algorithm is executed to solve it.

If $f(x)$ and $g(x)$ are nonconvex, additional difficulties can occur. In this case, nonunique, local solutions can be obtained at intermediate nodes, and consequently lower bounding properties would be lost. In addition, the nonconvexity in $g(x)$ can lead to locally infeasible problems at intermediate nodes, even if feasible solutions can be found in the corresponding leaf node. To overcome problems with nonconvexities, global solutions to relaxed NLPs can be solved at the intermediate nodes. This preserves the lower bounding information and allows nonlinear branch and bound to inherit the convergence properties from the linear case. However, as noted above, this leads to much more expensive solution strategies.

***Outer Approximation Decomposition Methods*** Again, we consider the MINLP Eq. (3-90) with convex $f(x)$ and $g(x)$. Note that the NLP with binary variables fixed at $\overline{y}$

$$\text{Min } f(x) + c^T \overline{y} \quad \text{subject to} \quad g(x) + B\overline{y} \le b \quad x \ge 0 \tag{3-91}$$

if feasible, leads to a solution that is an upper bound on the MINLP solution. In addition, linearizations of a convex function $\phi(x)$ leads to underestimation of the function itself, i.e.,

$$\phi(x) \ge \phi(x^k) + \nabla\phi(x^k)^T (x - x^k) \tag{3-92}$$

Consequently, linearization of Eq. (3-90) at a point $x^k$, to form the problem

$$\begin{aligned} \text{Min } & f(x^k) + \nabla f(x^k)^T (x - x^k) + c^T y \\ \text{subject to } & g(x^k) + \nabla g(x^k)^T (x - x^k) + By \le b \\ & x \ge 0 \qquad y \in \{0,1\}^t \end{aligned} \tag{3-93}$$

leads to overapproximation of the feasible region and underapproximation of the objective function in Eq. (3-90). Consequently, solution of Eq. (3-93) is a lower bound to the solution of Eq. (3-90). Adding more linearizations from other points does not change the bounding property, so for a set of points $x^l$, $l = 1, \ldots, k$, the problem

$$\begin{aligned} \text{Min } & \alpha \\ \text{subject to } & \left.\begin{aligned} \alpha &\ge f(x^l) + \nabla f(x^l)^T (x - x^l) + c^T y \\ g(x^l) &+ \nabla g(x^l)^T (x - x^l) + By \le b \end{aligned}\right\} \; l = 1, \ldots k \\ & x \ge 0 \qquad y \in \{0,1\}^t \end{aligned} \tag{3-94}$$

where $\alpha$ is a scalar variable, still has a solution that is a lower bound to Eq. (3-90). The outer approximation strategy is depicted in Fig. 3-59.

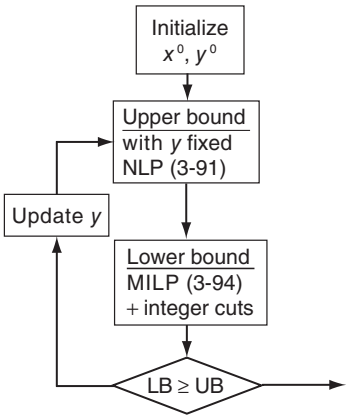

**FIG. 3-59** Outer approximation MINLP algorithm.

The outer approximation algorithm first initializes the process, either with a predetermined starting guess or by solving a relaxed NLP based on Eq. (3-90). An upper bound to the solution is then generated by fixing the binary variables to their current values $y^k$ and solving the NLP Eq. (3-91). This solution determines the continuous variable values $x^k$ for the MILP Eq. (3-94). [If Eq. (3-94) is an infeasible problem, any point may be chosen for $x^k$, or the linearizations could be omitted.] Note that this MILP also contains linearizations from previous solutions of Eq. (3-91). Finally, the integer cut $\sum |y_i - y_i^k| \geq 1$ is added to Eq. (3-94) to avoid revisiting previously encountered values of binary variables. Solution of Eq. (3-94) yields new values of $y$ and (without the integer cut) must lead to a lower bound to the solution of Eq. (3-90). Consequently, if the objective function of the lower bounding MILP is greater than the least upper bound determined in solutions of Eq. (3-91), then the algorithm terminates. Otherwise, the new values of $y$ are used to solve the next NLP Eq. (3-91).

Compared to nonlinear branch and bound, the outer approximation algorithm usually requires very few solutions of the MILP and NLP subproblems. This is especially advantageous on problems where the NLPs are large and expensive to solve. Moreover, there are three variations of outer approximation that may be suitable for particular problem types:

In *generalized benders decomposition* (GBD) the lower bounding problem Eq. (3-94) is replaced by the MILP

$$\begin{aligned} &\text{Min } \alpha \text{ subject to} \quad x \geq 0, y \in \{0,1\}^t \\ &\left.\begin{aligned} \alpha \geq f(x^l) + c^T y + [g(x^l) + By]^T \nu^l \\ \sum_i |y_i - y_i^l| \geq 1 \end{aligned}\right\} \; l = 1,\ldots,k \end{aligned} \tag{3-95}$$

where $\nu^l$ is the vector of KKT multipliers from the solution of Eq. (3-91) at iteration $l$. This MILP can be derived through a reformulation of the MILP used in Fig. 3-59 with the *inactive constraints* from Eq. (3-91) dropped. Solution of Eq. (3-95) leads to a weaker lower bound than Eq. (3-94), and consequently, more solutions of the NLP and MILP subproblems are needed to converge to the solution. However, Eq. (3-95) contains only a single continuous variable and far fewer inequality constraints and is much less expensive to solve than Eq. (3-94). Thus, GBD is favored over outer approximation if Eq. (3-91) is relatively inexpensive to solve or solution of Eq. (3-94) is too expensive.

The *extended cutting plane* (ECP) algorithm is complementary to GBD. While the lower bounding problem in Fig. 3-59 remains essentially the same, the continuous variables $x^k$ are chosen from the MILP solution and the NLP Eq. (3-91) is replaced by a simple evaluation of the objective and constraint functions. As a result, only MILP problems [Eq. (3-94) plus integer cuts] need to be solved. Consequently, the ECP approach has weaker upper bounds than outer approximation and requires more MILP solutions. It has advantages over outer approximation when the NLP Eq. (3-91) is expensive to solve.

The third extension to the outer approximation approach is based on a *branch-and-cut algorithm*, which solves a continuous linear program at each node of the search tree, and therefore improves the lower bounds while branching on integer variables. BONMIN, a comprehensive MINLP code described in Bonami et al. ["An Algorithmic Framework for Convex Mixed Integer Nonlinear Programs," *Discrete Optimization* **5**(2): 186–204 (2008)] incorporates NLP branch and bound, branch and cut, and outer approximation as options, along with hybrids of these strategies.

Additional difficulties arise for the outer approximation algorithm and its GBD, ECP, and branch and cut extensions when either $f(x)$ or $g(x)$ is nonconvex. Under these circumstances, the lower bounding properties resulting from the linearization and formulation of the MILP subproblem are lost, and the MILP solution may actually exclude the solution of Eq. (3-90). Hence, these algorithms need to be applied with care to nonconvex problems. To deal with nonconvexities, one can relax the linearizations in Eq. (3-94) through the introduction of additional *deviation variables* that can be penalized in the objective function. Alternately, the linearizations in Eq. (3-94) can be replaced by valid underestimating functions, such as those derived for global optimization [e.g., Eq. (3-86)]. However, this requires specific structural knowledge of Eq. (3-90) and may lead to weak lower bounds for the resulting MILP.

Finally, the performance of both MILP and MINLP algorithms is strongly dependent on the problem formulations Eq. (3-89) and Eq. (3-90). In particular, the efficiency of the approach is impacted by the lower bounds produced by the relaxation of the binary variables and subsequent solution of the linear program in the branch and bound tree. A number of approaches have been proposed to improve the quality of the lower bounds, including these:

- Logic-based methods such as *generalized disjunctive programming* (GDP) can be used to formulate MINLPs with fewer discrete variables that have tighter relaxations. The imposition of logic-based constraints prevents the generation of unsuitable alternatives, leading to less expensive searches. In addition, constrained logic programming (CLP) methods offer efficient alternatives to MILP solvers for highly combinatorial problems. See Jain and Grossmann, *INFORMS Journal of Computing*, **13:** 258–276 (2001) for more details.
- Convex hull formulations of MILPs and MINLPs lead to relaxed problems that have much tighter lower bounds. This leads to the examination of far fewer nodes in the branch and bound tree. See Grossmann and Lee, *Comput. Optim. Applic.* **26:** 83 (2003) for more details.
- *Reformulation* and *preprocessing* strategies including bound tightening of the variables, coefficient reduction, lifting facets, and special ordered set constraints frequently lead to improved lower bounds and significant performance improvements in mixed integer programming algorithms. See Bixby, R., and E. Rothberg, *Annals of Operations Research*, **49**(1): 37–41 (2007) for more details.

A number of efficient codes are available for the solution of MINLPs, including AlphaECP, BARON, BONMIN, DICOPT, MINLP, and SBB. All are available within the GAMS modeling platform.

## DEVELOPMENT OF OPTIMIZATION MODELS

The most important aspect to a successful optimization study is the formulation of the optimization model. These models must reflect the real-world problem so that meaningful optimization results are obtained; they also must satisfy the properties of the problem classes in Fig. 3-53. For instance, NLPs addressed by gradient-based methods need to have functions that are defined in the variable domain and have bounded and continuous first and second derivatives. In mixed integer problems, proper formulations are also needed to yield good lower bounds for efficient search. With increased understanding of optimization methods and the development of efficient and reliable optimization codes, optimization practitioners now focus on the *formulation* of optimization models that are realistic, well posed, and inexpensive to solve. Finally, convergence properties of NLP, MILP, and MINLP solvers require accurate first (and often second) derivatives from the optimization model. If these contain numerical errors (say, through finite difference approximations), then the performance of these solvers can deteriorate considerably. As a result of these characteristics, modeling platforms are essential for the formulation task. These are classified into two broad areas: optimization modeling platforms and simulation platforms with optimization.

*Optimization modeling platforms* provide general-purpose interfaces for optimization algorithms and remove the need for the user to interface to the solver directly. These platforms allow the general formulation for all problem classes discussed above with direct interfaces to state-of-the-art optimization codes. Three representative platforms are GAMS (General Algebraic Modeling Systems), AMPL (A Mathematical Programming Language), and AIMMS (Advanced Integrated Multidimensional Modeling Software). All three require problem model input via a declarative modeling language and provide exact gradient and hessian information through automatic differentiation strategies. Although it is possible, these platforms were not designed to handle externally added procedural models. As a result, these platforms are best applied on optimization models that can be developed entirely within their modeling framework. Nevertheless, these platforms are

widely used for large-scale research and industrial applications. In addition, the MATLAB platform allows for flexible formulation of optimization models as well, although it currently has only limited capabilities for automatic differentiation and limited optimization solvers.

*Simulation platforms with optimization* are often dedicated, application-specific modeling tools to which optimization solvers have been interfaced. These lead to very useful optimization studies, but because they were not originally designed for optimization models, they need to be used with some caution. In particular, most of these platforms do not provide exact derivatives to the optimization solver; often they are approximated through finite differences. In addition, the models themselves are constructed and calculated through numerical procedures, instead of through an open declarative language. Examples of these include widely used process simulators such as Aspen/Plus, PRO/II, and Hysys. Also note that more recent platforms such as Aspen Custom Modeler, GPROMS, and MOSAIC include declarative models and exact first derivatives.

Finally, for optimization tools that must be linked to procedural models, reliable and efficient automatic differentiation (AD) tools that provide exact first (often second) derivatives are available that link to models written in C, C++, FORTRAN, Python, and other modeling platforms. Example AD tools include ADIC, ADOL-C, CasADi, CppAD, and TAPENADE. When used with care, these can be applied to existing procedural models and, when linked to modern NLP and MINLP algorithms, can lead to powerful optimization capabilities.

## INTRODUCTION

Statistics represents a body of knowledge that enables one to deal with quantitative data reflecting any degree of uncertainty. There are six basic aspects of applied statistics:

1. Type of data
2. Random variables
3. Models
4. Parameters
5. Sample statistics
6. Characterization of chance occurrences

From these can be developed strategies and procedures for dealing with (1) estimation and (2) inferential statistics. The following has been directed more toward inferential statistics because of its broader utility.

Detailed illustrations and examples are used throughout to develop basic statistical methodology for dealing with a broad area of applications. If you are new to statistics, look first at the examples and find one that is appropriate to your application. In addition to this material, there are many specialized topics as well as some very subtle areas that have not been discussed. The references should be used for more detailed information. Section 8 discusses the use of statistics in statistical process control (SPC).

**Type of Data** In general, statistics deals with two types of data: counts and measurements. Counts represent the number of discrete outcomes, such as the number of defective parts in a shipment, the number of lost-time accidents, and so forth. Measurement data are treated as a continuum. For example, the tensile strength of a synthetic yarn theoretically could be measured to any degree of precision. A subtle aspect associated with count and measurement data is that some types of count data can be dealt with through the application of techniques that have been developed for measurement data alone. This ability is due to the fact that some simplified measurement statistics serve as an excellent approximation for the more tedious count statistics.

**Random Variables** Applied statistics deals with quantitative data. In tossing a fair coin the successive outcomes would tend to be different, with heads and tails occurring randomly over time. Given a long strand of synthetic fiber, the tensile strength of successive samples would tend to vary significantly from sample to sample. Counts and measurements are characterized as random variables, that is, observations which are susceptible to chance. Virtually all quantitative data are susceptible to chance in one way or another.

**Models** Part of the foundation of statistics consists of the mathematical models that characterize an experiment. The models themselves are mathematical ways of describing the probability, or relative likelihood, of observing specified values of random variables. For example, in tossing a coin once, a random variable $x$ could be defined by assigning to $x$ the value 1 for a head and 0 for a tail. Given a fair coin, the probability of observing a head on a toss would be .5, and similarly for a tail. Therefore, the mathematical model governing this experiment can be written as

| $x$ | $P(x)$ |
|---|---|
| 0 | .5 |
| 1 | .5 |

where $P(x)$ stands for what is called a *probability function.* This term is reserved for count data, in that probabilities can be defined for particular outcomes. The probability function that has been displayed is a very special case of the more general case, which is called the *binomial probability distribution.*

For measurement data which are considered continuous, the term *probability density* is used. For example, consider a spinner wheel which conceptually can be thought of as being marked off on the circumference infinitely precisely from 0 up to, but not including, 1. In spinning the wheel, the probability of the wheel's stopping at a specified marking point at any particular $x$ value, where $0 \le x < 1$, is 0, for example, stopping at the value $x = \sqrt{.5}$. For the spinning wheel, the probability density function would be defined by $f(x) = 1$ for $0 \le x < 1$. Graphically, this is shown in Fig. 3-60. The relative probability concept refers to the fact that density reflects the relative likelihood of occurrence; in this case, each number between 0 and 1 is equally likely. For measurement data, probability is defined by the area under the curve between specified limits. A density function always must have a total area of 1.

***Example*** For the density of Fig. 3-60

$$P[0 \le x \le .4] = .4 \qquad P[.2 \le x \le .9] = .7 \qquad P[.6 \le x < 1] = .4$$

and so forth. Since the probability associated with any particular point value is zero, it makes no difference whether the limit point is defined by a closed interval ($\le$ or $\ge$) or an open interval ($<$ or $>$).

Many different types of models are used as the foundation for statistical analysis. These models are also referred to as *populations.*

**Parameters** As a way of characterizing probability functions and densities, certain types of quantities called *parameters* can be defined. For example, the center of gravity of the distribution is defined to be the population mean, which is designated as $\mu$. For the coin toss $\mu = .5$, which corresponds to the average value of $x$; i.e., for one-half of the time $x$ will take on a value 0 and for the other half a value 1. The average would be .5. For the spinning wheel, the average value would also be .5.

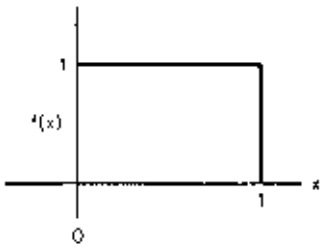

**FIG. 3-60** Density function.

Another parameter is called the *standard deviation*, which is designated as σ. The square of the standard deviation is used frequently and is called the *variance* $\sigma^2$. Basically, the standard deviation is a quantity which measures the spread or dispersion of the distribution from its mean μ. If the spread is broad, then the standard deviation will be larger than if it were more constrained.

For specified probability and density functions, the respective *mean*, or *expected value* $E(x)$, *variance* $\mathrm{Var}(x)$, and *standard deviation* σ are defined by the following:

| Probability functions (discrete variables and counts) | Probability density functions (continuous variables) |
|---|---|
| $E(x)=\mu=\sum_x x\,p(x)$ | $E(x)=\mu=\int_x x\,f(x)\,dx$ |
| $\mathrm{Var}(x)=\sigma^2=\sum_x (x-\mu)^2\,P(x)$ | $\mathrm{Var}(x)=\sigma^2=\int_x (x-\mu)^2 f(x)\,dx$ |

**Sample Statistics** Many types of sample statistics will be defined. Two very special types are the *sample mean*, designated as $\bar{x}$, and the *sample standard deviation*, designated as *s*. These are, by definition, random variables. Parameters such as μ and σ are not random variables; they are fixed constants corresponding to a probability function or distribution.

***Example*** In an experiment, six random numbers (rounded to four decimal places) were observed from the uniform distribution $f(x)=1$ for $0 \le x < 1$:

0.1009, 0.3754, 0.0842, 0.9901, 0.1280, 0.6606

The *sample mean* corresponds to the arithmetic average of the observations, which will be designated as $x_1$ through $x_6$, where

$$\bar{x}=\frac{1}{n}\sum_{i=1}^{n} x_i \text{ with } n=6 \quad \bar{x}=0.3899 \tag{3-96}$$

The *sample standard deviation s* is defined by the computation

$$s=\sqrt{\frac{\sum(x_i-\bar{x})^2}{n-1}}=\sqrt{\frac{n\sum x_i^2-(\sum x_i)^2}{n(n-1)}} \tag{3-97}$$

In effect, this represents the root of a statistical average of the squares. The divisor quantity $n-1$ will be referred to as the *degrees of freedom*. The sample value of the standard deviation for the data given is .3686.

The value of $n-1$ is used in the denominator because the deviations from the sample average must total zero, or

$$\sum(x_i-\bar{x})=0$$

Thus knowing $n-1$ values of $x_i-\bar{x}$ permits calculation of the *n*th value of $x_i-\bar{x}$.

The sample mean and sample standard deviation are obtained by using Microsoft Excel with the commands AVERAGE(B2:B7) and STDEV(B2:B7) when the observations are in cells B2 to B7.

In effect, the standard deviation quantifies the relative magnitude of the deviation numbers, i.e., a special type of "average" of the distance of points from their center. In statistical theory, it turns out that the corresponding variance quantities $s^2$ have remarkable properties which make possible broad generalities for sample statistics and therefore also their counterparts, the standard deviations.

For the corresponding population, the parameter values are μ = .50 and σ = .2887, which are obtained by calculating the integrals defined above with $f(x)=1$ and integrating *x* from 0 to 1. If, instead of using individual observations only, averages of 6 were reported, then the corresponding population parameter values would be μ = .50 and $\sigma_{\bar{x}}=\sigma/\sqrt{6}=.1179$. The corresponding variance for an average will be written occasionally as $\mathrm{Var}(\bar{x})=\mathrm{var}(x)/n$. In effect, the variance of an average is inversely proportional to the sample size *n*, which reflects the fact that sample averages will tend to cluster much more closely than individual observations. This is illustrated in greater detail under Measurement Data and Sampling Densities.

**Characterization of Chance Occurrences** To deal with a broad area of statistical applications, it is necessary to characterize the way in which random variables will vary by chance alone. The basic foundation for this characteristic is laid through a density called the *gaussian*, or *normal*, *distribution*.

Determining the area under the normal curve is a very tedious procedure. However, by standardizing a random variable that is normally distributed, it is possible to relate all normally distributed random variables to one table. The standardization is defined by the identity $z=(x-\mu)/\sigma$, where *z* is called the *unit normal*. Further, it is possible to standardize the sampling distribution of averages $\bar{x}$ by the identity $z=(\bar{x}-\mu)/(\sigma/\sqrt{n})$.

A remarkable property of the normal distribution is that, almost regardless of the distribution of *x*, sample averages $\bar{x}$ will approach the gaussian distribution as *n* gets large. Even for relatively small values of *n*, of about 10, the approximation in most cases is quite close. For example, sample averages of size 10 from the uniform distribution will have essentially a gaussian distribution. Also, in many applications involving count data, the normal distribution can be used as a close approximation. In particular, the approximation is quite close for the binomial distribution within certain guidelines.

The normal probability distribution function can be obtained in Microsoft Excel by using the NORM.DIST function and supplying the desired mean and standard deviation. The cumulative value can also be determined. In the MATLAB Statistics Toolbox the corresponding command is normcdf(*x*, μ, σ).

## ENUMERATION DATA AND PROBABILITY DISTRIBUTIONS

**Introduction** Many types of statistical applications are characterized by enumeration data in the form of counts. Examples are the number of lost-time accidents in a plant, the number of defective items in a sample, and the number of items in a sample that fall within several specified categories.

The sampling distribution of count data can be characterized through probability distributions. In many cases, count data are appropriately interpreted through their corresponding distributions. However, in other situations analysis is greatly facilitated through distributions which have been developed for measurement data. Examples of each will be illustrated in the following subsections.

**Binomial Probability Distribution**

***Nature*** Consider an experiment in which each outcome is classified into one of two categories, one of which will be defined as a success and the other as a failure. Given that the probability of success *p* is constant from trial to trial, then the probability of observing a specified number of successes *x* in *n* trials is defined by the binomial distribution. The sequence of outcomes is called a *Bernoulli process.*

***Nomenclature*** Let $\hat{p}=x/n$ be the proportion of successes in *n* trials.

***Probability Law***

$$p(x)=p\left(\frac{x}{n}\right)=\binom{n}{x}p^x(1-p)^{n-x} \quad x=0,1,2,\ldots,n$$

where $\binom{n}{x}=\dfrac{n!}{n!(n-x)!}$

***Properties***

$$E(x)=np \qquad \mathrm{Var}(x)=np(1-p)$$
$$E(\hat{p})=p \qquad \mathrm{Var}(\hat{p})=p(1-p)/n$$

***Example*** In three tosses of a coin, what is the probability of seeing three heads? This problem uses the binomial probability distribution because each toss is independent of the previous ones. Assuming the coins are "fair" and the probability of heads is ½, then the probability of 3 heads in 3 tosses is

$$P=\frac{3!}{3!0!}\left(\frac{1}{2}\right)^3\left(\frac{1}{2}\right)^0=\frac{1}{8}$$

Likewise, the probability of 2 heads and 1 tail in 3 tosses is

$$P=\frac{3!}{2!1!}\left(\frac{1}{2}\right)^2\left(\frac{1}{2}\right)^1=\frac{3}{8}$$

**Geometric Probability Distribution**

***Nature*** Consider an experiment in which each outcome is classified into one of two categories, one of which will be defined as a success and the other as a failure. Given that the probability of success *p* is constant from

trial to trial, then the probability of observing the first success on the $x$th trial is defined by the geometric distribution.

***Probability Law***

$$P(x) = p(1-p)^{x-1} \qquad x = 1, 2, 3, \ldots$$

***Properties***

$$E(x) = 1/p \quad \text{Var}(x) = (1-p)/p^2$$

If the event is described as $y = x - 1$, that is, $y$ is the number of failures before the first success, then

$$E(y) = (1-p)/p \qquad \text{Var}(x) = (1-p)/p^2$$

***Example*** Let $y$ be the number of tosses of a die prior to the toss in which a 2 or 3 first appears. Since the probability of a 2 or 3 in a single toss is 1/3, the probability function of $x$ and the expected value is

$$E(y) = \frac{1-p}{p} = \frac{1-1/3}{1/3} = 2$$

That is, you will (on average) do two tosses *before* you get a 2 or 3. Likewise, the expected value of getting your first 2 or 3 on the $x$th toss is

$$E(x) = \frac{1}{p} = \frac{1}{1/3} = 3$$

The difference between these is simply in the first case you are counting the tosses before the "success" and in the second case you are including the toss giving the "success."

**Poisson Probability Distribution**

***Nature*** The Poisson probability distribution is used to assess the number of events that will occur in a span of time, regardless of when the event occurred last, provided you know the average rate of events and the events are independent of the time since the last event. For example, in monitoring a moving thread line, one criterion of quality would be the frequency of broken filaments. These can be identified as they occur through the thread line by a broken filament detector mounted adjacent to the thread line. In this context, the random occurrences of broken filaments can be modeled by the Poisson distribution. This is called a *Poisson process* and corresponds to a probabilistic description of the frequency of defects or, in general, what are called arrivals at points on a continuous line or in time. Other examples include these:

1. The number of cars (arrivals) that pass a point on a high-speed highway between 10:00 and 11:00 A.M. on Wednesdays
2. The number of customers arriving at a bank between 10:00 and 10:10 A.M.
3. The number of telephone calls received through a switchboard between 9:00 and 10:00 A.M.
4. The number of insurance claims that are filed each week
5. The number of spinning machines that break down during 1 day at a large plant.

***Nomenclature***

$x$ = total number of arrivals in a total length $L$ or total period $T$
$a$ = average rate of arrivals for a unit length or unit time
$\lambda = aL$ = expected or average number of arrivals for the total length $L$
$\lambda = aT$ = expected or average number of arrivals for the total time $T$

***Probability Law*** Given that $a$ is constant for the total length $L$ or period $T$, the probability of observing $x$ arrivals in some period $L$ or $T$ is given by

$$P(x) = \frac{\lambda^x}{x!} e^{-\lambda} \qquad x = 0, 1, 2, \ldots$$

***Properties***

$$E(x) = \lambda \qquad \text{Var}(x) = \lambda$$

***Example*** The number of broken filaments in a thread line has been averaging .015 per yard. What is the probability of observing exactly two broken filaments in the next 100 yd? In this example, $a$ = .015/yd and $L$ = 100 yd; therefore $\lambda = (.015)(100) = 1.5$:

$$P(x = 2) = \frac{(1.5)^2}{2!} e^{-1.5} = .2510$$

***Example*** A commercial item is sold in a retail outlet as a unit product. In the past, sales have averaged 10 units per month with no seasonal variation. The retail outlet must order replacement items 2 months in advance. If the outlet starts the next 2-month period with 25 items on hand, what is the probability that it will run out of stock before the end of the second month?

Given $a$ = 10/month, then $\lambda = 10 \times 2 = 20$ for the total period of 2 months:

$$P(x \geq 26) = \sum_{26}^{\infty} p(x) = 1 - \sum_{0}^{25} p(x)$$

$$\sum_{0}^{25} \frac{20^x}{x!} e^{-20} = e^{-20}\left[1 + \frac{20}{1} + \frac{20^2}{2!} + \cdots + \frac{20^{25}}{25!}\right]$$

$$= 0.888$$

Therefore $P(x \geq 26) = .112$ or roughly an 11 percent chance of a stockout.

**Hypergeometric Probability Distribution**

***Nature*** In an experiment in which one samples from a relatively small group of items, each of which is classified in one of two categories, A or B, the hypergeometric distribution can be defined. One example is the probability of drawing two red and two black cards from a deck of cards. The hypergeometric distribution is the analog of the binomial distribution when successive trials are not independent, i.e., when the total group of items is not infinite. This happens when the drawn items are not replaced.

| | Population | Sample |
|---|---|---|
| Category A | $X$ | $x$ |
| Category B | $N-X$ | $n-x$ |
| Total | $N$ | $n$ |

***Probability Law***

$$P(x) = \binom{N-X}{n-x}\binom{X}{x} \Big/ \binom{N}{n}$$

$$E(x) = \frac{nX}{N}$$

$$\text{var}(x) = n\frac{X}{N}\frac{N-X}{N}\frac{N-n}{N-1}$$

***Example*** What is the probability that an appointed special committee of 4 has no female members when the members are randomly selected from a candidate group of 10 males and 7 females? Here $N = 17$, $X = 7$, $n = 4$, $x = 0$, and

$$P(x = 0) = \frac{\binom{10}{4}\binom{7}{0}}{\binom{17}{4}} = .0882$$

This distribution can be used in Texas Hold'em poker. See http: en.wikipedia.org/wiki/Hypergeometric-distribution.

To compute these probabilities in Microsoft Excel, put the value of $x$ in cell B2, say, and use the functions

Binomial distribution: = BINOM.DIST(B2, $n$, $p$, 0)
Poisson distribution: = POISSON.DIST(B2, $\lambda$, 0)
Hypergeometric distribution: = HYPGEOM.DIST(B2, $n$, $X$, $N$, 1)

The factorial function is FACT($n$) in Microsoft Excel and factorial($n$) in MATLAB. Be sure that $x$ is an integer.

**Conditional Probability** It is useful to predict the probability of one event, given that a second event has already occurred. For example, suppose you draw a card from a deck of 52 cards, half red and half black (event A). The probability of the first card being red is 26/52 = 1/2. But suppose the question is: What is the probability that the first two cards drawn are red (without replacing the first card)? In the second draw (event B) there are

only 25 red cards of 51 total cards, so that the probability of drawing a red card is 25/51. Then the probability of drawing two red cards is

$$P(\mathrm{AB}) = \left(\frac{1}{2}\right)\left(\frac{25}{51}\right) = \frac{25}{102}$$

This is sometimes written as

$$P(\mathrm{A} \cap \mathrm{B})$$

i.e., the probability of both events A and B occurring.

The $P(\mathrm{B}|\mathrm{A})$ is called the *conditional probability* of event B, given that event A has occurred. Conditional probabilities satisfy the general equation

$$P(\mathrm{B}|\mathrm{A}) = \frac{P(\mathrm{AB})}{P(\mathrm{A})} \quad \text{if} \quad P(\mathrm{A}) \neq 0$$

which is a restatement of the numerical equation in a different form, $P(\mathrm{B}|\mathrm{A}) = 25/51$, $P(\mathrm{A}) = 1/2$, and $P(\mathrm{AB}) = 25/102$. Likewise

$$P(\mathrm{A}|\mathrm{B}) = \frac{P(\mathrm{AB})}{P(\mathrm{B})} \quad \text{if} \quad P(\mathrm{B}) \neq 0$$

The probabilities satisfy Bayes' theorem

$$P(\mathrm{A}|\mathrm{B}) = \frac{P(\mathrm{B}|\mathrm{A})P(\mathrm{A})}{P(\mathrm{B}|\mathrm{A})P(\mathrm{A}) + P(\mathrm{B}|\mathrm{A}^c)P(\mathrm{A}^c)}$$

where $\mathrm{A}^c$ is the complement of A, that is, A did not occur.

***Example*** The table below gives the numbers of Bachelor's degrees in engineering in the United States in 2013–2014. Given that a graduate is a woman, what is the probability that she obtained a degree in chemical engineering, biological engineering, or biomedical engineering?

| | Total | Women | % Women |
|---|---|---|---|
| Aerospace | 3695 | 510 | 13.8 |
| Biological/Biomedical | 6150 | 2573 | 41.8 |
| Chemical | 8110 | 2944 | 36.3 |
| Civil | 12333 | 2393 | 19.4 |
| Civil/Environ. | 1893 | 573 | 30.3 |
| Electrical | 14088 | 1927 | 13.7 |
| Mechanical | 23675 | 3196 | 13.5 |
| Materials | 1440 | 379 | 26.3 |
| Industrial | 4877 | 1541 | 31.6 |
| subtotal | 76261 | 16036 | 21.0 |
| Other | 22912 | 3303 | 14.4 |
| Total | 99173 | 19339 | 19.5 |

The data are from the American Society of Engineering Education, ASEE Report 11-47.pdf, Brian L. Yoder, accessed July 14, 2015. http://www.asee.org/papers-and-publications/publications/college-profiles/14EngineeringbytheNumbersPart1.pdf

Define event A as being a female graduate, B as graduating in chemical engineering (male or female), C as graduating in biological/biomedical engineering (male or female). We thus have

$$P(\mathrm{A}) = 19339/99173 = 0.1950,\ P(\mathrm{B}) = 8110/99173 = 0.0818$$

$$P(\mathrm{C}) = 6150/99173 = 0.0620$$

Also $P(\mathrm{AB}) = 2944/99173 = 0.02968$.

We want $P(\mathrm{B}|\mathrm{A})$ which is $P(\mathrm{AB})/P(\mathrm{A}) = 0.02968/0.19500 = 0.152$. This should be the same as 2944/19339, which it is. Likewise $P(\mathrm{C}|\mathrm{A}) = 0.133$. Since events B and C are independent, the probability of a woman graduate being in one of these fields is the sum of these, or 0.285. This is considerably higher than the probability of a graduate being a woman, .195; or if one looks just at the other engineering fields, the probability of a woman graduate being in them is only .163.

## MEASUREMENT DATA AND SAMPLING DENSITIES

This section describes the probability of measurement data. If the number of samples is large, the data often form a normal distribution, so that is discussed first. If the sample size is smaller (somewhat less than 30), the data may be described by the *t* distribution. The chi-square test allows us to find whether an observed frequency of observation differs significantly from those expected from a model. Finally, the *F* test is used to compare variances and their properties. While tables exist to compute the various functions, here the commands will be given to compute them using Microsoft Excel. Similar commands are available in MATLAB and Mathematica.

| Microsoft Excel command | Designated symbol | Variable | Sampling distribution of |
|---|---|---|---|
| NORM.DIST($X$, μ, σ, 0) | $z$ | $\frac{x-\mu}{\sigma}$ | Observations* |
| NORM.DIST($X$, μ, σ, 0) | $z$ | $\frac{\bar{x}-\mu}{\sigma/\sqrt{n}}$ | Averages |
| TINV(α, df) | $t$ | $\frac{\bar{x}-\mu}{s/\sqrt{n}}$ | Averages when σ is unknown* |
| CHIINV(α, df) | $\chi^2$ | $(s^2/\sigma^2)(\mathrm{df})$ | Variances* |
| FINV(α, $\mathrm{df}_1$, $\mathrm{df}_2$) | $F$ | $s_1^2/s_2^2$ | Ratio of two independent sample variances* |

*When sampling from a gaussian distribution.

**Normal Distribution** The most common probability density function is the gaussian or normal probability function. This function describes a bell-shaped curve that indicates the probability of a measurement deviating from the average of many measurements. The formula is

$$f(x, \mu, \sigma) = \frac{1}{\sqrt{2\pi}\,\sigma} \exp\left[-\frac{(x-\mu)^2}{2\sigma^2}\right]$$

The curve is typically scaled so that the mean μ is 0; the symbol σ is the standard deviation, see Fig. 3-61. The area under the curve is 1.0. The Microsoft Excel function NORM.DIST($x$, μ, σ, 1) gives the probability that a sample measurement is less than $x$ when the measurements have a mean of μ and a standard deviation of σ, that is, the integral from negative infinity to $x$. For example, NORM.DIST(1, 0, 1, 1) (mean 0 and standard deviation of 1) gives the value .8413. Thus, the probability of a measurement $x$ being less than 1 (i.e., the mean plus 1 standard deviation) is .8413. NORM.DIST(−1, 0, 1, 1) gives the value .1587 for the probability of a measurement being less than −1, or less than the mean minus 1 standard deviation. Thus, the probability that $x$ is between +1 standard deviation and −1 standard deviation is .8413 − .1587 = .6827. The probability of a measurement falling within 2 standard

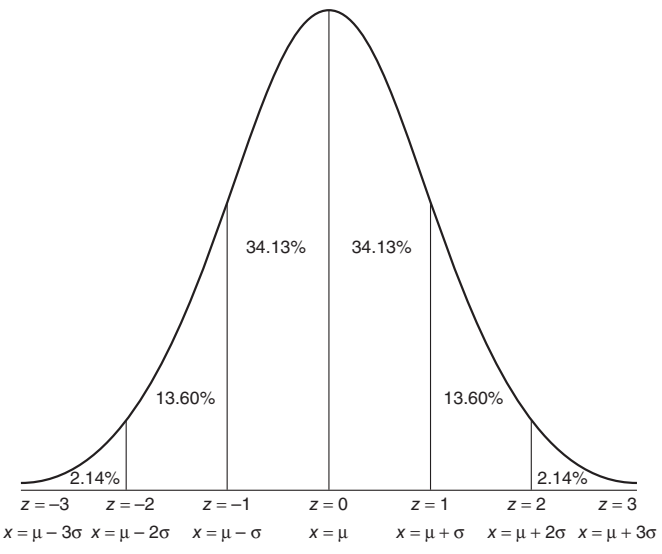

**FIG. 3-61** Normal probability distribution.

deviations of the mean is .9545, and the probability of a measurement falling with 3 standard deviations of the mean is 0.9975. In the Excel formulas, the last 1 is a logical variable and can be replaced by TRUE ( for 1).

The *standard normal variable* is defined as

$$z = \frac{x - \mu}{\sigma}$$

Then $z$ is a normal random variable with a mean of 0 and a standard deviation of 1. Likewise, $x = \mu + \sigma z$.

***Example*** Suppose one measures the concentration of some product coming off a production line. After 25 measurements one computes the average of 5.2 (in some units) with a variance of .15, using Eqs. (3-96) and (3-97). One believes the variation is randomly distributed so that it would be modeled by the normal distribution. What is the probability that a product will have the concentration between 5.0 and 5.4? The first method uses the data as they come. Calculate NORM.DIST(5.4, 5.2, .15, 1) = .90879 to get the probability that the concentration is below 5.4 and NORM.DIST(5.0, 5.2, .15, 1) = .09121 to get the probability that the concentration is below 5.0. The probability that the concentration is between 5.0 and 5.4 is then .90879 − .09121 = .81758, or 82 percent.

An alternative solution is to calculate the standard normal variables.

$$z = \frac{5.4 - 5.2}{0.15} = 1.33333 \quad \text{and} \quad z = \frac{5.0 - 5.2}{0.15} = -1.33333$$

Then NORM.DIST(1.33333, 0, 1, 1) − NORM.DIST(−1.33333, 0, 1, 1) = .90879 − .09121 = .81758.

The *central limit theorem* says that a set of random variables approaches a normal distribution as $n$, the number of measurements, goes to infinity. In addition, averages turn out to vary less than individual measurements. Suppose one calculates the average of $n$ concentrations this week, next week, etc. The corresponding relationship for the $Z$ scale is

$$z = \frac{\bar{x} - \mu}{\sigma}\sqrt{n} \quad \text{or} \quad \bar{x} = \mu + \frac{\sigma}{\sqrt{n}} z$$

The Microsoft Excel command CONFIDENCE(α, σ, $n$) gives the confidence interval about the mean for a sample size $n$, where σ is the standard deviation and α is the confidence level.

***Example*** Suppose one makes measurements of the concentration several times a week, and the average and variance of individual measurements are as given above. For a variance of 0.15, at a 95 percent confidence level what is the probable range of measurements?

The formula CONFIDENCE(0.05, 0.15, 100) = 0.0293. Thus, with 95 percent confidence the weekly averages will be 5.2 ± 0.029 or between 4.91 and 5.49.

***t* Distribution of Averages** The normal curve relies on a knowledge of σ, or in special cases, when it is unknown, $s$ can be used with the normal curve as an approximation when $n > 30$. For example, with $n > 30$ the intervals $\pm s$ and $\pm 2s$ will include roughly 68 and 95 percent of the sample values, respectively, when the distribution is normal.

In applications, sample sizes are usually small and σ is unknown. In these cases, the $t$ distribution can be used where

$$t = (\bar{x} - \mu)(s/\sqrt{n}) \quad \text{or} \quad \bar{x} = \mu + ts\sqrt{n}$$

See Fig. 3-62. The $t$ distribution is also symmetric and centered at zero. It is said to be robust in the sense that even when the individual observations $x$ are not normally distributed, sample averages of $x$ have distributions that tend toward normality as $n$ gets large. Even for small $n$ of 5 through 10, the approximation is usually relatively accurate. It is sometimes called the Student's $t$ distribution.

Since the $t$ distribution relies on the sample standard deviation $s$, the resultant distribution will differ according to the sample size $n$. To designate this difference, the respective distributions are classified according to what are called the *degrees of freedom* and abbreviated as df. In simple problems, the df are just the sample size minus 1. In general, degrees of freedom are the number of quantities minus the number of constraints. The mathematical definition of the $t$ distribution is

$$A(t, \mathrm{df}) = \frac{1}{\mathrm{df}^{1/2} B\left(\frac{1}{2}, \frac{\mathrm{df}}{2}\right)} \int_{-t}^{t} \left(1 + \frac{x^2}{\mathrm{df}}\right)^{\frac{df+1}{2}} dx$$

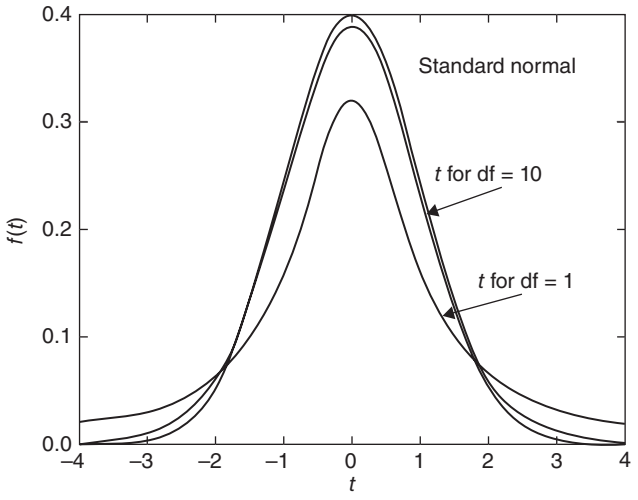

**FIG. 3-62** The $t$ distribution function.

where $B$ is the incomplete beta function. $A(t, \mathrm{df})$ is the probability, for degrees of freedom df, that a certain statistic $t$ (measuring the observed difference of means) would be smaller than the observed value if the means were in fact the same. Limiting values are $A(0, \mathrm{df}) = 0$ and $A(\infty, \mathrm{df}) = 1$. The Microsoft Excel function TDIST($X$, df,1) gives the right-tail probability, and TDIST($X$, df, 2) gives twice that. The probability that $t \le X$ is 1 − TDIST($X$, df, 1) when $X \ge 0$ and TDIST(abs($X$), df, 1) when $X < 0$. The probability that $-X \le t \le +X$ is 1 − TDIST($X$, df, 2). To find the limits for a given confidence level, one uses the Microsoft Excel function TINV(α, df). For a two-tailed distribution, to achieve 95 percent confidence, the two tails represent 2.5 percent each, and one uses α = 0.05.

***Example*** For a sample size $n$ = 5, what values of $t$ define a midarea of 90 percent? For 4 df using Microsoft Excel, TINV(.1, 4) = 2.132. Thus, $P[-2.132 \le t \le 2.132] = .90$. Also, TDIST(2.132, 4, 2) = 0.10 and 1 − TDIST(2.132, 4, 2) = 0.90.

***t* Distribution for the Difference in Two Sample Means with Equal Variances.** The $t$ distribution can be readily extended to the difference in two sample means when the respective populations have the same variance. Calculate the sample means $\bar{x}_1$ and $\bar{x}_2$ and sample variances $s_1^2$ and $s_2^2$, with sample sizes $n_1$ and $n_2$, respectively. The variance is estimated by pooling the sum of variances of both samples.

$$s_p^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{(n_1 - 1) + (n_2 - 1)} \tag{3-98}$$

The significance of the difference is measured by the ratio of the difference to its standard deviation, and it is denoted by $t$.

$$t = \frac{\bar{x}_1 - \bar{x}_2}{s_p\sqrt{1/n_1 + 1/n_2}} = \frac{\bar{x}_1 - \bar{x}_2}{s_p\sqrt{\frac{n_1 + n_2}{n_1 n_2}}} \tag{3-99}$$

***Example*** Suppose we have two sets of data, each with 10 degrees of freedom. The means are 5.23 and 4.95, and the pooled sample variance is 0.3. Are these significantly different at the 10 percent level? Equation (3-99) gives

$$t = \frac{5.23 - 4.95}{\left|0.3\sqrt{\frac{10 + 10}{10 * 10}}\right|} = 2.09$$

There are 20 − 2 = 18 degrees of freedom, and TINV(0.1,18) = 1.07. Thus, the probability that $t$ is between +1.07 and −1.07 is $P[-1.07 \le t \le 1.07] = .90$. These data are significantly different, and the hypothesis that they are from the same distribution is disproved.

***t* Distribution for the Difference in Two Sample Means with Unequal Variances** When population variances are unequal, an approximate $t$ quantity can be used:

with
$$t=\frac{\bar{x}_1-\bar{x}_2-(\mu_1-\mu_2)}{\sqrt{a+b}}$$
$$a=s_1^2/n_1 \quad b=s_2^2/n_2$$

and
$$\text{df}=\frac{(a+b)^2}{a^2/(n_1-1)+b^2(n_2-1)}=2.09$$

**Chi-Square Distribution** For some industrial applications, product uniformity is of primary importance. The sample standard deviation $s$ is most often used to characterize uniformity. In dealing with this problem, the chi-square distribution can be used where $\chi^2=(s^2/\sigma^2)$ (df). The chi-square distribution is a family of distributions which are defined by the degrees of freedom associated with the sample variance. For most applications, df is equal to the sample size minus 1. See Fig. 3-63.

The probability density function is

$$C(\chi^2,\text{df})=\frac{(\chi^2)^{\text{df}/2-1}}{2^{\text{df}/2}\Gamma(\text{df}/2)}e^{-\chi^2/2}$$

and the integral with respect to $\chi^2$ from 0 to infinity is 1.0 and $\Gamma$ is the gamma function. The cumulative probability function $P(\chi^2, \text{df})$ is the integral of $C$ from 0 to $\chi^2$; different functions are obtained for different degrees of freedom. A plot of $C$ is shown in Fig. 3-63 for 3 and 5 df. The shaded area gives the probability that the chi-squared for a correct model with df degrees of freedom is more than $\chi^2$, here 0.0373. Thus the probability that the $\chi^2$ is larger than 9.2 is .0373. Since the number is small, it means that the probability of getting a $\chi^2$ that large or larger is 3.7 percent. The null hypothesis is that the two samples are from the same normal distribution. If the probability is very small, then there is evidence to reject the hypothesis. If the probability is larger, one can only say that the hypothesis is accepted. That is so because one example cannot prove a statement, but it can disprove a statement.

Also

$$P[\chi_1^2\le(s^2/\sigma^2)(\text{df})\le\chi_2^2]=1-\alpha$$

where $\chi_1^2$ corresponds to a lower-tail area of $\alpha/2$ and $\chi_2^2$ to an upper-tail area of $\alpha/2$. The basic underlying assumption for the mathematical derivation of chi squared is that a random sample was selected from a normal distribution with variance $\sigma^2$. When the population is not normal but skewed, chi-squared probabilities could be substantially in error.

***Example*** On the basis of a sample size $n=5$, what midrange of values will include the sample ratio $s/\sigma$ with a probability of 95 percent?

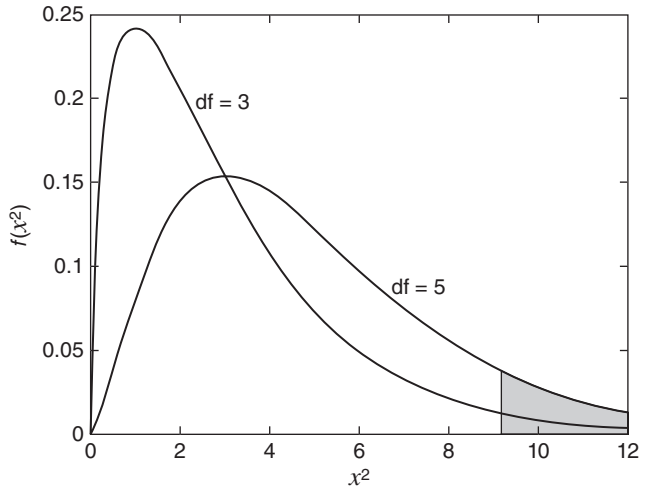

**FIG. 3-63** The $\chi^2$ distribution function.

We use the Microsoft Excel function CHIINV to answer this. CHIINV (0.025, 4) = 11.1 and CHIINV(0.975, 4) = 0.484. Then

$$P[.484\le(s^2/\sigma^2)(4)\le 11.1]=.95$$

or
$$P[.35\le s/\sigma\le 1.66]=.95$$

This states that the sample standard deviation will be at least 35 percent and not more than 166 percent of the population variance 95 percent of the time. Conversely, 5 percent of the time the standard deviation will underestimate or overestimate the population standard deviation by the corresponding amount.

The chi-squared distribution can be applied to other types of application which are of an entirely different nature. These include applications discussed under Goodness-of-Fit Test and Two-Way Test for Independence of Count Data. In these applications, the mathematical formulation and context are entirely different, but they do result in the same table of values.

***F* Distribution** To test if two samples are from the same population, it is necessary to test whether the means are the same and variances are the same, within some confidence level. The test for variances is done using the $F$ test. The null hypothesis is that the two samples are from the same population. The *F ratio* is defined by the ratio of sample variances.

$$F(\text{df}_1,\text{df}_2)=s_1^2/s_2^2$$

Here $\text{df}_1$ and $\text{df}_2$ correspond to the respective df's for the sample variances. The $F$ distribution, similar to the chi-squared distribution, is sensitive to the basic assumption that sample values were selected randomly from a normal distribution. The Microsoft Excel function FINV(percent, $\text{df}_1$, $\text{df}_2$) gives the largest ratio (and the reciprocal gives the smallest ratio) that agrees with the null hypothesis at that level of significance.

***Example*** For two sample variances with 4 df each, what limits will bracket their ratio with a midarea probability of 90 percent?

Use FINV with 4 df and Percent = 0.05 (to get both sides totaling 10 percent). FINV(.05, 4, 4) gives 6.39. Thus

$$P[1/6.39\le s_1^2/s_2^2\le 6.39]=.90$$

or
$$P[.40\le s_1/s_2\le 2.53]=.90$$

FDIST($X$, $\text{df}_1$, $\text{df}_2$) gives the upper percentage points of the $F$ distribution. FDIST(6.39, 4, 4) = 0.05.

**Confidence Interval for a Mean** Suppose a change has been made in a process and one wishes to assess the confidence of the population mean (unknown). Thus, one wants

$$P\left[\bar{x}-t\frac{s}{\sqrt{n}}\le\mu\le\bar{x}+t\frac{s}{\sqrt{n}}\right]=1-\alpha$$

where $t$ is defined for an upper-tail area of $\alpha/2$ with $n-1$ df. In this application, the interval $\bar{x}-ts/\sqrt{n}$ limits are random variables which will cover the unknown parameter $\mu$ with probability $1-\alpha$. The converse—that we are $100(1-\alpha)$ percent sure that the parameter value is within the interval—is not correct. This statement defines a probability for the parameter rather than the probability for the interval. The probability density function is the $t$ distribution and uses the Microsoft Excel commands TDIST and TINV.

***Example*** For the example in Normal Distribution, the sample variance of 25 measurements was 0.15. What is the 90 percent confidence interval for $\mu$?

Using $\text{df}=n-1=24$, $\bar{x}=5.2$, $s^2=0.15$, and a 10 percent value in Microsoft Excel

TINV(0.10, 24) gives $t=1.71$. Thus

$$P\left[5.2-1.71\sqrt{\frac{0.15}{24}}<\mu<5.2+1.71\sqrt{\frac{0.15}{24}}\right]=.90$$

or
$$P(5.065\le\mu\le 5.335)=0.90$$

**Confidence Interval for the Difference in Two Population Means** The confidence interval for a mean can be extended to include

the difference between two population means. This interval is based on the assumption that the respective populations have the same variance $\sigma^2$:

$$\bar{x}_1 - \bar{x}_2 - ts_p\sqrt{1/n_1 + 1/n_2} \le \mu_1 - \mu_2 \le \bar{x}_1 - \bar{x}_2 + ts_p\sqrt{1/n_1 + 1/n_2}$$

The value of $t$ is obtained from the $t$ distribution, Microsoft Excel function TINV($\alpha$, df). To achieve 95 percent confidence, use $\alpha = 0.05$.

**Confidence Interval for a Variance** The chi-square distribution can be used to derive a confidence interval for a population variance $\sigma^2$ when the parent population is normally distributed. For a $100(1 - \alpha)$ percent confidence interval

$$\frac{(\text{df})s^2}{\chi_2^2} \le \sigma^2 \le \frac{(\text{df})s^2}{\chi_1^2}$$

where $\chi_1^2$ corresponds to a lower-tail area of $\alpha/2$ and $\chi_2^2$ to an upper-tail area of $\alpha/2$.

***Example*** For the example in Normal Distribution, the sample variance of 25 measurements was 0.15. What is range of the population variance $\sigma^2$ for a 90 percent confidence interval?

Using df $= n - 1 = 24$, $s^2 = 0.15$, and 5 percent and 95 percent values in Microsoft Excel function CHIINV gives CHIINV(0.05, 24) = 13.85 and CHIINV(0.95, 24) = 36.42. Thus

$$\frac{24(0.15)}{36.4} \le \sigma^2 \le \frac{24(0.15)}{13.8}$$

or

$$0.0989 \le \sigma^2 \le 0.261$$

$$0.31 \le \sigma \le 0.51$$

Thus, the population variance will be between 0.0989 and 0.261 with 90 percent confidence.

## TESTS OF HYPOTHESIS

**General Nature of Tests** The general nature of tests can be illustrated with a simple example. In a court of law, when a defendant is charged with a crime, the judge instructs the jury initially to presume that the defendant is innocent of the crime. The jurors are then presented with evidence and counterargument as to the defendant's guilt or innocence. If the evidence suggests beyond a reasonable doubt that the defendant did, in fact, commit the crime, the jurors have been instructed to find the defendant guilty; otherwise, not guilty. The burden of proof is on the prosecution. Jury trials represent a form of decision making. In statistics, an analogous procedure for making decisions falls into an area of statistical inference called *hypothesis testing.*

Suppose that a company has been using a certain supplier of raw materials in one of its chemical processes. A new supplier approaches the company and states that its material, at the same cost, will increase the process yield. If the new supplier has a good reputation, the company might be willing to run a limited test. On the basis of the test results it would then make a decision to change suppliers or not. Good management would dictate that an improvement must be demonstrated (beyond a reasonable doubt) for the new material. That is, the burden of proof is tied to the new material. In setting up a test of hypothesis for this application, the initial assumption would be defined as a null hypothesis and symbolized as $H_0$. The null hypothesis would state that yield for the new material is no greater than for the conventional material. The symbol $\mu_0$ would be used to designate the known current level of yield for the standard material and $\mu$ for the unknown population yield for the new material. Thus, the *null hypothesis* can be symbolized as $H_0$: $\mu \le \mu_0$. The alternative to $H_0$ is called the *alternative hypothesis* and is symbolized as $H_1$: $\mu > \mu_0$. To prove the alternative hypothesis, we must show that the null hypothesis is not valid within some probability.

Given a series of tests with the new material, the average yield $\bar{x}$ would be compared with $\mu_0$. If $\bar{x} < \mu_0$, the new supplier would be dismissed. If $\bar{x} > \mu_0$, the question would be: Is it sufficiently greater in the light of its corresponding reliability, i.e., beyond a reasonable doubt? If the confidence interval for $\mu$ included $\mu_0$, the answer would be no; but if it did not include $\mu_0$, the answer would be yes. In this simple application, the formal test of hypothesis would result in the same conclusion as that derived from the confidence interval. However, the utility of tests of hypothesis lies in their generality, whereas confidence intervals are restricted to a few special cases.

***Nomenclature for All Examples***

$\mu$ = mean of the population or differences from which the sample has been drawn

$\sigma$ = standard deviation of the population or differences from which the sample has been drawn

$\mu_0$ = base or reference level

$H_0$ = null hypothesis

$H_1$ = alternative hypothesis

$\alpha$ = significance level, usually set at .10, .05, or .01

$n$ = number of observations

$t$ = $t$ value corresponding to the significance level $\alpha$. For a two-tailed test, each corresponding tail would have an area of $\alpha/2$, and for a one-tailed test, one-tail area would be equal to $\alpha$. If $\sigma^2$ is known, then $z$ would be used rather than $t$.

**Test of Hypothesis for a Mean Procedure**

$$t = (\bar{x} - \mu_0)/(s/\sqrt{n}) \text{ sample value of the test statistic}$$

***Assumptions***

1. The $n$ observations $x_1, x_2, \ldots, x_n$ have been selected randomly.
2. The population from which the observations were obtained is normally distributed with an unknown mean $\mu$ and standard deviation $\sigma$. In actual practice, this is a robust test, in the sense that in most types of problems it is not sensitive to the normality assumption when the sample size is 10 or greater.

***Test of Hypothesis***

1. The null hypothesis is that the sample came from a population whose mean $\mu$ is equivalent to some base or reference designated by $\mu_0$. This can take one of the three forms shown in Table 3-4.
2. If the null hypothesis is assumed to be true, say, in form 1, then the distribution of the test statistic $t$ is known. Given a random sample in a two-sided test, one can predict how far its sample value of $t$ might be expected to deviate from zero (the midvalue of $t$) by chance alone. If the sample value of $t$ does, in fact, deviate too far from zero, then this is defined to be sufficient evidence to refute the assumption of the null hypothesis. It is consequently rejected, and the converse or alternative hypothesis is accepted.
3. The rule for accepting $H_0$ is specified by selection of the $\alpha$ level, as indicated in Fig. 3-64. For forms 2 and 3 the $\alpha$ area is defined to be in the upper and the lower tail, respectively. The parameter $\alpha$ is the probability of rejecting the null hypothesis when it is actually true.
4. The decision rules for each of the three forms are defined as follows: If the sample $t$ falls within the acceptance region, accept $H_0$ for lack of contrary evidence. If the sample $t$ falls in the critical region, reject $H_0$ at a significance level of $100\alpha$ percent.

**TABLE 3-4 Options for Null Hypothesis and Alternate Hypothesis**

| Form 1 | Form 2 | Form 3 |
|---|---|---|
| $H_0$: $\mu = \mu_0$ | $H_0$: $\mu \le \mu_0$ | $H_0$: $\mu \ge \mu_0$ |
| $H_1$: $\mu \ne \mu_0$ | $H_1$: $\mu > \mu_0$ | $H_1$: $\mu < \mu_0$ |
| Two-tailed test | Upper-tailed test | Lower-tailed test |

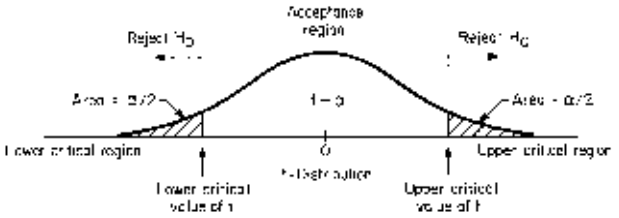

**FIG. 3-64** Acceptance region for two-tailed test. For a one-tailed test, area = $\alpha$ on one side only.

***Example***

*Application.* In the past, the yield for a chemical process has been established at 89.6 percent with a standard deviation of 3.4 percent. A new supplier of raw materials will be used and tested for 7 days. [Note: many problems with chemical processes arise because of bad raw materials.]

*Procedure*

1. The standard of reference is $\mu_0 = 89.6$ with a known $\sigma = 3.4$.
2. It is of interest to demonstrate whether an increase in yield is achieved with the new material; $H_0$ says it has not; therefore,

$$H_0: \mu \le 89.6 \qquad H_1: \mu > 89.6$$

3. Select $\alpha = .05$, and since $\sigma$ is known (assuming the new material would not affect the day-to-day variability in yield), we use $z$. The corresponding critical value is TINV(0.10, ∞) = 1.645. Remember TINV is the value for the two-tailed distribution, so the one-tailed distribution is TINV(2α, df).
4. The decision rule is

Accept $H_0$ if sample $z < 1.645$.

Reject $H_0$ if sample $z > 1.645$.

5. A 7-day test was carried out, and daily yields averaged 91.6 percent with a sample standard deviation $s = 3.6$ (this is not needed for the test of hypothesis).
6. For the data sample $z = (91.6 - 89.6)/(3.4/\sqrt{7}) = 1.56$.
7. Since this is less than 1.645, accept the null hypothesis for lack of contrary evidence; i.e., an improvement has not been demonstrated beyond a reasonable doubt.

***Example***

*Application.* In the past, the break strength of a synthetic yarn has averaged 34.6 lb. The first-stage draw ratio of the spinning machines has been increased. Production management wants to determine whether the break strength has changed under the new condition.

*Procedure*

1. The standard of reference is $\mu_0 = 34.6$.
2. It is of interest to demonstrate whether a change has occurred; therefore,

$$H_0: \mu = 34.6 \qquad H_1: \mu \ne 34.6$$

3. Select $\alpha = .05$, and since with the change in draw ratio the uniformity might change, the sample standard deviation would be used, and therefore $t$ would be the appropriate test statistic.
4. A sample of 21 ends was selected randomly and tested on an Instron with the results $\bar{x} = 35.55$ and $s = 2.041$.
5. For 20 df and a two-tailed α level of 5 percent, TINV(0.05, 20) = ±2.086.

Accept $H_0$ if $-2.086 <$ sample $t < 2.086$.

Reject $H_0$ if sample $t < -2.086$ or $t > 2.086$.

6. For the data sample $t = (35.55 - 34.6)/(2.041/\sqrt{21}) = 2.133$.
7. Since $2.133 > 2.086$, reject $H_0$ and accept $H_1$. It has been demonstrated that an improvement in break strength has been achieved.

**Two-Population Test of Hypothesis for Means**

***Nature*** Two samples were selected from different locations in a plastic-film sheet and measured for thickness. The thickness of the respective samples was measured at 10 close but equally spaced points in each of the samples. It was of interest to compare the average thickness of the respective samples to detect whether they were significantly different. That is, was there a significant variation in thickness between locations?

From a modeling standpoint, statisticians would define this problem as a two-population test of hypothesis. They would define the respective sample sheets as two populations from which 10 sample thickness determinations were measured for each.

To compare populations based on their respective samples, it is necessary to have some basis of comparison. This basis is predicated on the distribution of the $t$ statistic. In effect, the $t$ statistic characterizes the way in which two sample means from two separate populations will tend to vary by chance alone when the population means and variances are equal. Consider the following:

| Population 1 | | Population 2 | |
|---|---|---|---|
| Normal | Sample 1 | Normal | Sample 2 |
| $\mu_1$ | $n_1$ | $\mu_2$ | $n_2$ |
| | $\bar{x}_1$ | | $\bar{x}_2$ |
| $\sigma_1^2$ | $s_1^2$ | $\sigma_2^2$ | $s_2^2$ |

Consider the hypothesis $\mu_1 = \mu_2$. If, in fact, the hypothesis is correct, that is, $\mu_1 = \mu_2$ (under the condition $\sigma_1^2 = \sigma_2^2$), then the sampling distribution of $\bar{x}_1 - \bar{x}_2$ is predictable through the $t$ distribution. (We use $t$ rather than $z$ because the variance is unknown.) The observed sample values then can be compared with the corresponding $t$ distribution.

***Example***

*Application.* Two samples were selected from different locations in a plastic-film sheet. The thickness of the respective samples was measured at 10 close but equally spaced points.

*Procedure*

1. Demonstrate whether the thicknesses of the respective sample locations are significantly different from each other; therefore,

$$H_0: \mu_1 = \mu_2 \qquad H_1: \mu_1 \ne \mu_2$$

2. Select $\alpha = .05$.
3. Summarize the statistics for the respective samples:

| Sample 1 | | Sample 2 | |
|---|---|---|---|
| 1.473 | 1.367 | 1.474 | 1.417 |
| 1.484 | 1.276 | 1.501 | 1.448 |
| 1.484 | 1.485 | 1.485 | 1.469 |
| 1.425 | 1.462 | 1.435 | 1.474 |
| 1.448 | 1.439 | 1.348 | 1.452 |
| $\bar{x}_1 = 1.434$ | $s_1 = .0664$ | $\bar{x}_2 = 1.450$ | $s_2 = .0435$ |

4. The first step is to use the $F$ test on the ratio of sample variances. The null hypothesis is $H_0$: $\sigma_1^2 = \sigma_2^2$, and it would be tested against $H_1$: $\sigma_1^2 \ne \sigma_2^2$. Since this is a two-tailed test, the procedure is to use the largest ratio and the corresponding ordered degrees of freedom. However, since the largest ratio is arbitrary, it is necessary to define the true α level as twice the desired value. Therefore, using FINV(0.05, 9, 9) = 3.18 would be for a true $\alpha = .10$. For the sample,

$$\text{Sample } F = (.0664/.0435)^2 = 2.33$$

Therefore, the ratio of sample variances is no larger than one might expect to observe when in fact $\sigma_1^2 = \sigma_2^2$. There is not sufficient evidence to reject the null hypothesis that $\sigma_1^2 = \sigma_2^2$.

5. Turn next to the $t$ test. For 18 df and a two-tailed α level of 5 percent, the critical values of $t$ are given by TINV(0.05, 18) = ±2.101.
6. The decision rule is

Accept $H_0$ if $-2.101 \le$ sample $t \le 2.101$.

Reject $H_0$ otherwise.

7. For the sample the pooled variance estimate is given by Eq. (3-98).

$$s_p^2 = \frac{9(.0664)^2 + 9(.0435)^2}{9+9} = .00315, \; s_p = .056$$

8. The sample statistic value of $t$ is given by Eq. (3-99).

$$\text{Sample } t = \frac{1.434 - 1.450}{.056\sqrt{1/10 + 1/10}} = -.64$$

9. Since the sample value of $t$ falls within the acceptance region, accept $H_0$ for lack of contrary evidence; i.e., there is insufficient evidence to demonstrate that thickness differs between the two selected locations.

**Test of Hypothesis for Paired Observations**

***Nature*** In some types of applications, associated pairs of observations are defined. For example, (1) pairs of samples from two populations are treated in the same way, or (2) two types of measurements are made on the same unit. For applications of this type, it is not only more effective but also necessary to define the random variable as the difference between the pairs of observations. The difference numbers can then be tested by the standard $t$ distribution.

**Test of Hypothesis for Matched Pairs: Procedure**

***Nomenclature***

$d_i$ = sample difference between the $i$th pair of observations

$s$ = sample standard deviation of differences

$\mu$ = population mean of differences

$\sigma$ = population standard deviation of differences

$t$ = value with $(n-1)$ df

$t = (\bar{d} - \mu_0)/(s/\sqrt{n})$, the sample value of $t$

***Assumptions***

1. The $n$ pairs of samples have been selected and assigned for testing in a random way.

2. The population of differences is normally distributed with a mean $\mu$ and variance $\sigma^2$. As in the previous application of the $t$ distribution, this is a robust procedure, i.e., not sensitive to the normality assumption if the sample size is 10 or greater in most situations.

***Test of Hypothesis***

1. Under the null hypothesis, it is assumed that the sample came from a population whose mean $\mu$ is equivalent to some base or reference level, designated by $\mu_0$. For most applications of this type, the value of $\mu_0$ is defined to be zero; that is, it is of interest generally to demonstrate a difference not equal to zero. The hypothesis can take one of three forms shown in Table 3-4.

2. If the null hypothesis is assumed to be true, say, in the case of a lower-tailed test, form 3, then the distribution of the test statistic $t$ is known under the null hypothesis that limits $\mu = \mu_0$. Given a random sample, one can predict how far its sample value of $t$ might be expected to deviate from zero by chance alone when $\mu = \mu_0$. If the sample value of $t$ is too small, as in the case of a negative value, then this would be defined as sufficient evidence to reject the null hypothesis.

3. Select $\alpha$.

4. The critical values or value of $t$ would be defined by the value of $t$ with $n-1$ df corresponding to a tail area of $\alpha$. For a two-tailed test use TINV($\alpha$, df), and for a one-tailed test use TINV($2\alpha$, df).

5. The decision rule for each of the three forms would be to reject the null hypothesis if the sample value of $t$ fell in that area of the $t$ distribution defined by $\alpha$, which is called the *critical region*. Otherwise, the alternative hypothesis would be accepted for lack of contrary evidence.

***Example, Two-Sided Test***

*Application.* Pairs of pipes have been buried in 11 different locations to determine corrosion on nonbituminous pipe coatings for underground use. One type includes a lead-coated steel pipe and the other a bare steel pipe.

*Procedure*

1. The standard of reference is taken as $\mu_0 = 0$, corresponding to no difference in the two types.

2. It is of interest to demonstrate whether either type of pipe has a greater corrosion resistance than the other. Therefore,

$$H_0: \mu = 0 \qquad H_1: \mu \neq 0$$

3. Select $\alpha = .05$. TINV(0.05, 10) = 2.228.

4. The decision rule is then

Accept $H_0$ if $-2.228 \leq$ sample $t \leq 2.228$

Reject $H_0$ otherwise

5. The sample of 11 pairs of corrosion determinations and their differences is as follows:

| Soil type | Lead-coated steel pipe | Bare steel pipe | $d$ = difference |
|---|---|---|---|
| A | 27.3 | 41.4 | −14.1 |
| B | 18.4 | 18.9 | −0.5 |
| C | 11.9 | 21.7 | −9.8 |
| D | 11.3 | 16.8 | −5.5 |
| E | 14.8 | 9.0 | 5.8 |
| F | 20.8 | 19.3 | 1.5 |
| G | 17.9 | 32.1 | −14.2 |
| H | 7.8 | 7.4 | 0.4 |
| I | 14.7 | 20.7 | −6.0 |
| J | 19.0 | 34.4 | −15.4 |
| K | 65.3 | 76.2 | −10.9 |

6. The sample statistics, Eq. (3-97)

$$\bar{d} = -6.245 \quad s^2 \frac{11\sum d^2 - (\sum d)^2}{11 \times 10} = 52.59$$

or

$$s = 7.25$$

$$\text{Sample } t = (-6.245 - 0)/(7.25/\sqrt{11})$$

$$= -2.86$$

7. Since the sample $t$ of −2.86 < tabled $t$ of −2.228, reject $H_0$ and accept $H_1$; that is, it has been demonstrated that, on the basis of the evidence, lead-coated steel pipe has a greater corrosion resistance than bare steel pipe.

***Example, One-Sided Test***

*Application.* A stimulus was tested for its effect on blood pressure. Ten men were selected randomly, and their blood pressure was measured before and after the stimulus was administered. It was of interest to determine whether the stimulus had caused a significant increase in the blood pressure.

*Procedure*

1. The standard of reference was taken as $\mu_0 \leq 0$, corresponding to no increase.

2. It was of interest to demonstrate an increase in blood pressure if in fact an increase did occur. Therefore,

$$H_0: \mu_0 \leq 0 \qquad H_1: \mu_0 > 0$$

3. Select $\alpha = .05$. Since only increases are of interest, use a one-sided value TINV(0.05*2, 9) = 1.833.

4. The decision rule is

Accept $H_0$ if sample $t < 1.833$.

Reject $H_0$ if sample $t > 1.833$.

5. The sample of 10 pairs of blood pressure and their differences was as follows:

| Individual | Before | After | $d$ = difference |
|---|---|---|---|
| 1 | 138 | 146 | 8 |
| 2 | 116 | 118 | 2 |
| 3 | 124 | 120 | −4 |
| 4 | 128 | 136 | 8 |
| 5 | 155 | 174 | 19 |
| 6 | 129 | 133 | 4 |
| 7 | 130 | 129 | −1 |
| 8 | 148 | 155 | 7 |
| 9 | 143 | 148 | 5 |
| 10 | 159 | 155 | −4 |

6. The sample statistics:

$$\bar{d} = 4.4 \quad s = 6.85$$

$$\text{Sample } t = (44 - 0)/(6.85/\sqrt{10}) = 2.03$$

7. Since the sample $t$ = 2.03 > critical $t$ = 1.833, reject the null hypothesis. It has been demonstrated that the population of men from whom the sample was drawn tend, as a whole, to have an increase in blood pressure after the stimulus has been given. The distribution of differences $d$ seems to indicate that the degree of response varies by individuals.

**Test of Hypothesis for a Proportion**

***Nature*** Some types of statistical applications deal with counts and proportions rather than measurements. Examples are (1) the proportion

of workers in a plant who are out sick, (2) lost-time worker accidents per month, (3) defective items in a shipment lot, and (4) preference in consumer surveys.

The procedure for testing the significance of a sample proportion follows that for a sample mean. In this case, however, owing to the nature of the problem the appropriate test statistic is $Z$. This follows from the fact that the null hypothesis requires the specification of the goal or reference quantity $p_0$, and since the distribution is a binomial proportion, the associated variance under the null hypothesis is $[p_0(1-p_0)]n$. The primary requirement is that the sample size $n$ satisfy normal approximation criteria for a binomial proportion, roughly $np > 5$ and $n(1-p) > 5$.

**Test of Hypothesis for a Proportion: Procedure**

***Nomenclature***

$p$ = mean proportion of the population from which the sample has been drawn

$p_0$ = base or reference proportion

$[p_0(1-p_0)]/n$ = base or reference variance

$\hat{p} = x/n$ = sample proportion, where $x$ refers to the number of observations out of $n$ which have the specified attribute

$z = Z$ value corresponding to the significance level $\alpha$

$z = (\hat{p} - p_0)/\sqrt{p_0(1-p_0)/n}$, the sample value of the test statistic

***Assumptions***

1. The $n$ observations have been selected randomly.
2. The sample size $n$ is sufficiently large to meet the requirement for the $Z$ approximation.

***Test of Hypothesis***

1. Under the null hypothesis, it is assumed that the sample came from a population with a proportion $p_0$ of items having the specified attribute. For example, in tossing a coin the population could be thought of as having an unbounded number of potential tosses. If it is assumed that the coin is fair, this would dictate $p_0 = 1/2$ for the proportional number of heads in the population. The null hypothesis can take one of three forms:

| Form 1 | Form 2 | Form 3 |
|---|---|---|
| $H_0: p = p_0$ | $H_0: p \le p_0$ | $H_0: p \ge p_0$ |
| $H_1: p \ne p_0$ | $H_1: p > p_0$ | $H_1: p < p_0$ |
| Two-tailed test | Upper-tailed test | Lower-tailed test |

2. If the null hypothesis is assumed to be true, then the sampling distribution of the test statistic $Z$ is known. Given a random sample, it is possible to predict how far the sample proportion $x/n$ might deviate from its assumed population proportion $p_0$ through the $Z$ distribution. When the sample proportion deviates too far, as defined by the significance level $\alpha$, this serves as the justification for rejecting the assumption, that is, rejecting the null hypothesis.
3. The decision rule is given by

Form 1: Accept $H_0$ if lower critical $z <$ sample $z <$ upper critical $z$.
Reject $H_0$ otherwise.

Form 2: Accept $H_0$ if sample $z <$ upper critical $z$.
Reject $H_0$ otherwise.

Form 3: Accept $H_0$ if lower critical $z <$ sample $z$.
Reject $H_0$ otherwise.

***Example***

*Application.* A company has received a very large shipment of rivets. One product specification required that no more than 2 percent of the rivets have diameters greater than 14.28 mm. Any rivet with a diameter greater than this would be classified as defective. A random sample of 600 was selected and tested with a go–no go gauge. Of these, 16 rivets were found to be defective. Is this sufficient evidence to conclude that the shipment contains more than 2 percent defective rivets?

*Procedure*

1. The quality goal is $p \le .02$. It would be assumed initially that the shipment meets this standard; that is, $H_0: p \le .02$.
2. The assumption in step 1 would first be tested by obtaining a random sample. Under the assumption that $p \le .02$, the distribution for a sample proportion would be defined by the $z$ distribution. This distribution would define an upper bound corresponding to the upper critical value for the sample proportion. It would be unlikely that the sample proportion would rise above that value if, in fact, $p \le .02$. If the observed sample proportion exceeds that limit, corresponding to what would be a very unlikely chance outcome, this would lead one to question the assumption that $p \le .02$. That is, one would conclude that the null hypothesis is false. To test, set

$$H_0: p \le .02 \qquad H_1: p > .02$$

3. Select $\alpha = .05$.
4. With $\alpha = .05$, the upper critical value of $Z = \text{TINV}(0.05*2, \infty) = 1.645$ for a one-sided test.
5. The decision rule:

Accept $H_0$ if sample $z < 1.645$.
Reject $H_0$ if sample $z > 1.645$.

6. The sample $z$ is given by

$$\text{Sample } z = \frac{(16/600) - .02}{\sqrt{(.02)(.98)/600}} = 1.17$$

7. Since the sample $z < 1.645$, accept $H_0$ for lack of contrary evidence; there is not sufficient evidence to demonstrate that the defect proportion in the shipment is greater than 2 percent.

**Test of Hypothesis for Two Proportions**

***Nature*** In some types of engineering and management science problems, we may be concerned with a random variable that represents a proportion, for example, the proportional number of defective items per day. The method described previously relates to a single proportion. In this subsection two proportions will be considered.

A certain change in a manufacturing procedure for producing component parts is being considered. Samples are taken by using both the existing and the new procedures to determine whether the new procedure results in an improvement. In this application, it is of interest to demonstrate statistically whether the population proportion $p_2$ for the new procedure is less than the population proportion $p_1$ for the old procedure on the basis of a sample of data.

**Test of Hypothesis for Two Proportions: Procedure**

***Nomenclature***

$p_i$ = population $i = 1$ or 2 proportion

$n_i$ = sample size from population 1 or 2

$x_i$ = number of observations out of that have the designated attribute

$\hat{p}_i = x_i/n_i$, the sample proportion from population 1 or 2

$z = Z$ value corresponding to the stated significance level $\alpha$

$$z = \frac{\hat{p}_1 - \hat{p}_2}{\sqrt{\hat{p}_1(1-\hat{p}_1)/n_1 + \hat{p}_2(1-\hat{p}_2)/n_2}} \text{ the sample value of } Z$$

***Assumptions***

1. The respective two samples of $n_1$ and $n_2$ observations have been selected randomly.
2. The sample sizes $n_1$ and $n_2$ are sufficiently large to meet the requirement for the $Z$ approximation; that is, $x_1 > 5$ and $x_2 > 5$.

***Test of Hypothesis***

1. Under the null hypothesis, it is assumed that the respective two samples have come from populations with equal proportions $p_1 = p_2$. Under this hypothesis, the sampling distribution of the corresponding $Z$ statistic is known. On the basis of the observed data, if the resultant sample value of $Z$ represents an unusual outcome, that is, if it falls within the critical region, this would cast doubt on the assumption of equal proportions. Therefore, it will have been demonstrated statistically that the population proportions are in fact not equal. The various hypotheses can be stated:

| Form 1 | Form 2 | Form 3 |
|---|---|---|
| $H_0: p_1 = p_2$ | $H_0: p_1 \le p_2$ | $H_0: p_1 \ge p_2$ |
| $H_1: p_1 \ne p_2$ | $H_1: p_1 > p_2$ | $H_1: p_1 < p_2$ |
| Two-tailed test | Upper-tailed test | Lower-tailed test |

2. The decision rule for form 1 is given by

Accept $H_0$ if lower critical $z <$ sample $z <$ upper critical $z$.

Reject $H_0$ otherwise.

***Example***

*Application.* A change was made in a manufacturing procedure for component parts. Samples were taken during the last week of operations with the old procedure and during the first week of operations with the new procedure. Determine whether the proportional numbers of defects for the respective populations differ on the basis of the sample information.

*Procedure*

1. The hypotheses are

$$H_0: p_1 = p_2 \qquad H_1: p_1 \neq p_2$$

2. Select $\alpha = .05$. Therefore, the critical values of $z$ are $\pm 1.96$ since TINV$(0.05, \infty) = 1.96$.

3. For the samples, 75 out of 1720 parts from the previous procedure and 80 out of 2780 parts under the new procedure were found to be defective; therefore,

$$\hat{p}_1 = 75/1720 = .0436 \qquad \hat{p}_2 = 80/2780 = .0288$$

4. The decision rule:

Accept $H_0$ if $-1.96 \leq$ sample $z \leq 1.96$.

Reject $H_0$ otherwise.

5. The sample statistic:

$$\text{Sample } z = \frac{.0436 - .0288}{\sqrt{(.0436)(.9564)/1720 + (.0288)(.9712)/2780}} = 2.53$$

6. Since the sample $z$ of $2.53 > z = 1.96$, reject $H_0$ and conclude that the new procedure has resulted in a reduced defect rate.

**Goodness-of-Fit Test**

***Nature*** A standard die has six sides numbered from 1 to 6. If one were really interested in determining whether a particular die was well balanced, one would have to carry out an experiment. To do this, it might be decided to count the frequencies of outcomes, 1 through 6, in tossing the die $N$ times. On the assumption that the die is perfectly balanced, one would expect to observe $N/6$ occurrences each for 1, 2, 3, 4, 5, and 6. However, chance dictates that exactly $N/6$ occurrences each will not be observed. For example, given a perfectly balanced die, the probability is only 1 chance in 65 that one will observe 1 outcome each, for 1 through 6, in tossing the die 6 times. Therefore, an outcome different from 1 occurrence each can be expected. Conversely, an outcome of six 3s would seem to be too unusual to have occurred by chance alone.

Some industrial applications involve the concept outlined here. The basic idea is to test whether a group of observations follows a preconceived distribution. In the case cited, the distribution is uniform; i.e., each face value should *tend* to occur with the same frequency.

**Goodness-of-Fit Test: Procedure**

***Nomenclature*** Each experimental observation can be classified into one of $r$ possible categories or cells.

$r$ = total number of cells

$O_j$ = number of observations occurring in cell $j$

$E_j$ = expected number of observations for cell $j$ based on the preconceived distribution

$N$ = total number of observations $= \sum_{j=1}^{r} O_j$

df = degrees of freedom for the test. In general, this will be equal to $r - 1$ minus the number of statistical quantities on which the $E_j$'s are based (see the examples that follow for details).

***Assumptions***

1. The observations represent a sample selected randomly from a population that has been specified.

2. The number of expectation counts $E_j$ within each category should be roughly 5 or more. If an $E_j$ count is significantly less than 5, that cell should be pooled with an adjacent cell.

***Computation for $E_j$*** On the basis of the specified population, the probability of observing a count in cell $j$ is defined by $p_j$. For a sample of size $N$, corresponding to $N$ total counts, the expected frequency is given by $E_j = Np_j$.

***Test Statistics: Chi Square***

$$\chi^2 = \sum_{j=1}^{r} \frac{(O_j - E_j)^2}{E_j} \text{ with df degrees of freedom}$$

***Test of Hypothesis***

1. $H_0$: The sample came from the specified theoretical distribution.
   $H_1$: The sample did not come from the specified theoretical distribution.
2. For a stated level of $\alpha$,
   Reject $H_0$ if sample $\chi^2 >$ CHIINV $\chi^2$.
   Accept $H_0$ if sample $\chi^2 <$ CHIINV $\chi^2$.

***Example***

*Application.* A production-line product is rejected if one of its characteristics does not fall within specified limits. The standard goal is that no more than 2 percent of the production should be rejected.

*Computation*

1. Of 950 units produced during the day, 28 units were rejected; there are two cells, so $r = 2$.

2. The hypotheses:

$H_0$: process is in control

$H_1$: process is not in control

3. Assume that $\alpha = .05$; therefore, the critical value of $\chi^2(1)$ is CHIINV $(0.05, 1) = 3.84$.

4. The decision rule:

Reject $H_0$ if sample $\chi^2 > 3.84$.

Accept $H_0$ otherwise.

5. Since it is assumed that $p = .02$, this would dictate that in a sample of 950 there would be on average $(.02)(950) = 19$ defective items and 931 acceptable items:

| Category | Observed $O_j$ | Expectation $E_j = 950p_j$ |
|---|---|---|
| Acceptable | 922 | 931 |
| Not acceptable | 28 | 19 |
| Total | 950 | 950 |

$$\text{Sample } \chi^2 = \frac{(922 - 931)^2}{931} + \frac{(28 - 19)^2}{19}$$
$$= 4.35 \text{ with critical } \chi^2 = 3.84$$

6. Conclusion. Since the sample value exceeds the critical value, the process is not in control.

***Example***

*Application.* A frequency count of 52 workers was tabulated according to the number of defective items that they produced. An unresolved question is whether the observed distribution is a Poisson distribution. That is, do observed and expected frequencies agree within chance variation?

*Computation*

1. The hypotheses:
   $H_0$: there are no significant differences, in number of defective units, between workers.
   $H_1$: there are significant differences.
2. Assume that $\alpha = .05$.
3. Test statistic:

| No. of defective units $= n_j$ | $O_j$ | | $O_j n_j$ | $E_j$ | |
|---|---|---|---|---|---|
| 0 | 3 | 10 | 0 | 2.06 | 8.70 pool |
| 1 | 7 | | 7 | 6.64 | |
| 2 | 9 | | 18 | 10.73 | |
| 3 | 12 | | 36 | 11.55 | |
| 4 | 9 | | 36 | 9.33 | |
| 5 | 6 | | 30 | 6.03 | |
| 6 | 3 | 6 | 18 | 3.24 | 5.66 pool |
| 7 | 2 | | 14 | 1.50 | |
| 8 | 0 | | 0 | 0.60 | |
| 9 | 1 | | 9 | 0.22 | |
| ≥10 | 0 | | 0 | 0.10 | |
| Sum | 52 | | 168 | 52 | |

The expectation numbers $E_j$ were computed as follows: For the Poisson distribution, $\lambda = E(x)$; therefore, an estimate of $\lambda$ is the average number of defective units per worker, that is, $\lambda = (1/52)(0\times 3 + 1\times 7 + \cdots + 9\times 1) = 3.23$. Given this approximation, the probability of no defective units for a worker would be $(3.23)^0/0!)e^{-3.23} = .0396$. For the 52 workers, the number of workers producing no defective units would have an expectation $E = 52(0.0396) = 2.06$, and so forth.

The sample chi-square value is computed from

$$\chi^2 = \frac{(10-8.70)^2}{8.70} + \frac{(9-10.73)^2}{10.73} + \cdots + \frac{(6-5.66)^2}{5.66} = .522$$

4. The critical value of $\chi^2$ would be based on 4 degrees of freedom. This corresponds to $(r-1)-1=4$, since one statistical quantity $\lambda$ was computed from the sample and used to derive the expectation numbers.
5. The critical value of $\chi^2$ is CHIINV(0.05, 4) = 9.49; therefore, accept $H_0$.

**Two-Way Test for Independence for Count Data**

***Nature*** When individuals or items are observed and classified according to two different criteria, the resultant counts can be statistically analyzed. For example, a market survey may examine whether a new product is preferred and if it is preferred due to a particular characteristic.

Count data, based on a random selection of individuals or items which are classified according to two different criteria, can be statistically analyzed through the $\chi^2$ distribution. The purpose of this analysis is to determine whether the respective criteria are dependent. That is, is the product preferred because of a particular characteristic?

**Two-Way Test for Independence for Count Data: Procedure**

***Nomenclature***

1. Each observation is classified according to two categories:
   *a.* The first one into 2, 3, …, or $r$ categories
   *b.* The second one into 2, 3, …, or $c$ categories
2. $O_{ij}$ = number of observations (observed counts) in cell $(i, j)$ with
$$i = 1, 2, \ldots, r$$
$$j = 1, 2, \ldots, c$$
3. $N$ = total number of observations
4. $E_{ij}$ = computed number for cell $(i, j)$ which is an expectation based on the assumption that two characteristics are independent
5. $R_i$ = subtotal of counts in row $i$
6. $C_j$ = subtotal of counts in column $j$
7. $\chi^2$ = critical value of $\chi^2$ corresponding to the significance level $\alpha$ and $(r-1)(c-1)$ df
8. Sample $\chi^2 = \dfrac{\sum_{i,j}^{c,r}(O_{ij}-E_{ij})^2}{E_{ij}}$

***Assumptions***

1. The observations represent a sample selected randomly from a large total population.
2. The number of expectation counts $E_{ij}$ within each cell should be approximately 2 or more for arrays $3\times 3$ or larger. If any cell contains a number smaller than 2, appropriate rows or columns should be combined to increase the magnitude of the expectation count. For arrays $2\times 2$, approximately 4 or more are required; if the number is less than 4, the exact Fisher test should be used.

***Test of Hypothesis*** Under the null hypothesis, the classification criteria are assumed to be independent, i.e.,

$H_0$: criteria are independent
$H_1$: criteria are not independent

For the stated level of $\alpha$,

Reject $H_0$ if sample $\chi^2 >$ CHIINV $\chi^2$.
Accept $H_0$ otherwise.

***Computation for $E_{ij}$*** Compute $E_{ij}$ across rows or down columns by using either of the following identities:

$$E_{ij} = C_j\left(\frac{R_i}{N}\right) \quad \text{across rows}$$

$$E_{ij} = R_j\left(\frac{C_i}{N}\right) \quad \text{down columns}$$

***Sample $\chi^2$ Value***

$$\chi^2 = \sum_{i,j}\frac{(O_{ij}-E_{ij})^2}{E_{ij}}$$

In the special case of $r = 2$ and $c = 2$, a more accurate and simplified formula that does not require the direct computation of $E_{ij}$ can be used:

$$\chi^2 = \frac{\left[\left|O_{11}O_{22} - O_{12}O_{21}\right| - \tfrac{1}{2}N\right]^2 N}{R_1R_2C_1C_1}$$

***Example***

*Application.* A market research study was carried out to relate the subjective "feel" of a consumer product to consumer preference. In other words, is the consumer's preference for the product associated with the feel of the product, or is the preference independent of the product feel?

*Procedure*

1. It was of interest to demonstrate whether an association exists between feel and preference; therefore, assume
   $H_0$: feel and preference are independent
   $H_1$: they are not independent
2. A sample of 200 people was asked to classify the product according to two criteria:
   *a.* Liking for this product
   *b.* Liking for the feel of the product

| | | Like feel | | |
|---|---|---|---|---|
| | | Yes | No | $R_i$ |
| Like product | Yes | 114 | 13 | 127 |
| | No | 55 | 18 | 73 |
| | $C_j$ | 169 | 31 | 200 |

3. Select $\alpha = .05$; therefore, with $(r-1)(c-1) = 1$ df, the critical value of $\chi^2$ is CHIINV(0.05, 1) =3.84.
4. The decision rule:
   Accept $H_0$ if sample $\chi^2 < 3.84$.
   Reject $H_0$ otherwise.
5. The sample value of $\chi^2$ by using the special formula is

$$\text{Sample } \chi^2 = \frac{\left[\left|114\times 18 - 13\times 55\right| - 100\right]^2 200}{(169)(31)(127)(73)} = 6.30$$

6. Since the sample $\chi^2$ of 6.30 > CHIINV $\chi^2$ of 3.84, reject $H_0$ and accept $H_1$. The relative proportionality of $E_{11} = 169(127/200) = 107.3$ to the observed 114 compared with $E_{22} = 31(73/200) = 11.3$ to the observed 18 suggests that when the consumer likes the feel, the consumer tends to like the product, and conversely for not liking the feel. The proportions 169/200 = 84.5 percent and 127/200 = 63.5 percent suggest further that there are other attributes of the product which tend to nullify the beneficial feel of the product.

## LEAST SQUARES

When experimental data are to be fit with a mathematical model, it is necessary to allow for the fact that the data have errors. The engineer is interested in finding the parameters in the model as well as the uncertainty in their determination. In the simplest case, the model is a linear equation with only two parameters, and they are found by a least-squares minimization of the errors in fitting the data. Multiple regression is just linear least squares applied with more terms. Nonlinear regression allows the parameters of the model to enter in a nonlinear fashion. See Press et al. (2007) in General References for a description of maximum likelihood as it applies to both linear and nonlinear least squares. Since many calculators include least-squares calculations, the emphasis here is on the estimates and their uncertainty.

In a least-squares parameter estimation, it is desired to find parameters that minimize the sum of squares of the deviation between the experimental data and the theoretical equation.

$$\chi^2 = \sum_{i=1}^{N}\left[\frac{y_i - y(x_i; a_1, a_2, \cdots, a_M)}{\sigma_i}\right]^2$$

where $y_i$ is the $i$th experimental data point for the value $x_i$, $\sigma_i$ is the standard deviation for the $i$th point, $y_i$, $y(x_i; a_1, a_2, \ldots, a_M)$ is the theoretical equation at $x_i$, and the parameters $\{a_1, a_2, \ldots, a_M\}$ are to be determined to minimize $\chi^2$. If the uncertainties in $y_i$ are not known, then assume a constant $\sigma = \sigma_i$ for all $i$. After calculation the variance will be minimized, giving $\sigma$, and $\chi^2$ can be calculated.

$$\sigma^2 = \sum_{i=1}^{N} \frac{[y_i - y(x_i; a_1, a_2, \ldots, a_M)]^2}{N}$$

**Linear Least Squares** When the model is a straight line $y_i - a - bx_i$, one is minimizing

$$\chi^2 = \sum_{i=1}^{N} (y_i - a - bx_i)^2$$

The linear correlation coefficient $r$ is defined by

$$r = \frac{\sum_{i=1}^{N} (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^{N} (x_i - \bar{x})^2} \sqrt{\sum_{i=1}^{N} (y_i - \bar{y})^2}}$$

and

$$\chi^2 = (1 - r^2) \sum_{i=1}^{N} (y_i - \bar{y})^2$$

where $\bar{y}$ is the average of the $y_i$ values. Values of $r$ near 1 indicate a positive correlation; $r$ near −1 means a negative correlation, and $r$ near 0 means no correlation. These parameters are easily found by using standard programs.

The solution for $\hat{a}$ and $\hat{b}$ is

$$\hat{a} = \left( \sum_{i=1}^{N} x_i^2 \sum_{i=1}^{N} y_i - \sum_{i=1}^{N} x_i \sum_{i=1}^{N} x_i y_i \right) / \text{dem}$$

$$\hat{b} = \left( N \sum_{i=1}^{N} x_i y_i - \sum_{i=1}^{N} x_i \sum_{i=1}^{N} y_i \right) / \text{dem}$$

$$\text{dem} \equiv N \sum_{i=1}^{N} x_i^2 - \left( \sum_{i=1}^{N} x_i \right)^2$$

The variance of the estimate is the $\chi^2$ given above with the $N$ replaced by $N - 2$ since the line has two constraints.

$$s^2 = \sum_{i=1}^{N} (y_i - \hat{a} - \hat{b}x_i)^2 / (N - 2)$$

The variances of $\hat{a}$ and $\hat{b}$ are

$$s_{\hat{a}}^2 = \left( \frac{1}{N} + \frac{\bar{x}^2}{\sum_{i=1}^{N} (x_i - \bar{x})^2} \right) s^2 \quad \text{and} \quad s_{\hat{b}}^2 = \frac{s^2}{\sum_{i=1}^{N} (x_i - \bar{x})^2}$$

The solution is found in Microsoft Excel by putting the values for $x$ and $y$ in two columns (for example, A1:A10, B1:B10). The commands = SLOPE(A1:A10,B1-B10), INTERCEPT(A1:A10,B1-B10), and RSQ(A1:A10,B1-B10) give the slope, intercept, and residual squared. You can also use the LINEST function. See Microsoft Excel Help menu for the function LINEST which can give the statistics for multiple linear regression.

A $t$ test can give the significance. For example, using

$$t = \frac{\hat{b}}{s_{\hat{b}}}$$

with a two-sided test, the value would be rejected if outside the range given by $t(\alpha/2) = \text{TINV}(\alpha, N - 2)$ in Microsoft Excel.

When there are more terms, i.e., multiple linear regression, similar formulas can be found, usually using the computer. Estimates for the variances and $t$ tests are available, e.g., in Mendenhall and Sincich (2006). In Microsoft Excel, one simply adds columns to the spreadsheet for the additional independent variables.

**Polynomial Regression** In polynomial regression, one expands the function in a polynomial in $x$ and the same considerations apply.

$$y(x) = \sum_{j=1}^{M} a_j x^{j-1}$$

For $N$ measurements write this as

$$y_i = \sum_{j=1}^{M} a_j x_i^{j-1}$$

In Microsoft Excel, the instructions above hold with the columns $x_i^0, x_i^1, x_i^2, x_i^3$, etc.

**Multiple Nonlinear Regression** In multiple nonlinear regression, any set of functions can be used, not just polynomials, such as

$$y(x) = \sum_{j=1}^{M} = a_j f_j(x)$$

where the set of functions $\{f_j(x)\}$ is known and specified. Note that the unknown parameters $\{a_j\}$ enter the equation linearly. In this case, the spreadsheet can be expanded to have a column for $x$ and then successive columns for $f_j(x)$. Then this works in the same way as for linear multiple regression.

**Nonlinear Least Squares** There are no analytic methods for determining the most appropriate model for a particular set of data. In many cases, however, the engineer has some basis for a model. If the parameters occur in a nonlinear fashion, then the analysis becomes more difficult. For example, in relating the temperature to the elapsed time of a fluid cooling in the atmosphere, a model that has an asymptotic property would be the appropriate model (temp = $a + b$ exp($-c$ time), where $a$ represents the asymptotic temperature corresponding to $t \to \infty$). In this case, the parameter $c$ appears nonlinearly. The usual practice is to concentrate on model development and computation rather than on statistical aspects. In general, nonlinear regression should be applied only to problems in which there is a well-defined, clear association between the two variables; therefore, a test of hypothesis on the significance of the fit would be somewhat ludicrous. In addition, the generalization of the theory for the associate confidence intervals for nonlinear coefficients is not well developed.

***Example***

*Application.* Data were collected on the cooling of water in the atmosphere as a function of time.

*Sample data*

| Time $x$ | Temperature $y$ |
|---|---|
| 0 | 92.0 |
| 1 | 85.5 |
| 2 | 79.5 |
| 3 | 74.5 |
| 5 | 67.0 |
| 7 | 60.5 |
| 10 | 53.5 |
| 15 | 45.0 |
| 20 | 39.5 |

*Model.* The data are fit to the formula $y = a + be^{cx}$ using optimization techniques in MATLAB, giving $a = 33.54$, $b = 57.89$, $c = 0.11$. The value of $\chi^2$ is 1.83. Using an alternative form, $y = a + b/(c + x)$, gives $a = 9.872$, $b = 925.7$, $c = 11.27$, and $\chi = 0.19$. Since this model had a smaller value of $\chi^2$, it might be the chosen one, but it is only a fit of the specified data and may not be generalized beyond that. Both forms give equivalent plots.

## ERROR ANALYSIS OF EXPERIMENTS

Consider the problem of assessing the accuracy of a series of measurements. If measurements are for independent, identically distributed observations, then the errors are independent and uncorrelated. Then $\bar{y}$, the experimentally determined mean, varies about $E(y)$, the true mean, with variance $\sigma^2/n$, where $n$ is the number of observations in $\bar{y}$. Thus, if one measures something

several times today, and each day, and the measurements have the same distribution, then the variance of the means decreases with the number of samples in each day's measurement *n*. Of course, other factors (weather, weekends) may make the observations on different days *not* distributed identically.

Consider next the problem of estimating the error in a variable that cannot be measured directly but must be calculated based on results of other measurements. Suppose the computed value $Y$ is a linear combination of the measured variables $\{y_i\}$, $Y = \alpha_1 y_1 + \alpha_2 y_2 + \ldots$. Let the random variables $y_1, y_2, \ldots$ have means $E(y_1), E(y_2), \ldots$ and variances $\sigma^2(y_1), \sigma^2(y_2), \ldots$. The variable $Y$ has mean

$$E(Y) = \alpha_1 E(y_1) + \alpha_2 E(y_2) + \cdots$$

and variance (Cropley, 1978)

$$\sigma^2(Y) = \sum_{i=1}^{n} \alpha_i^2 \sigma_i^2(y_i) + 2\sum_{i=1}^{n}\sum_{j=i+1}^{n} \alpha_i \alpha_j \mathrm{Cov}(y_i, y_j)$$

If the variables are uncorrelated and have the same variance, then

$$\sigma^2(Y) = \left(\sum_{i=1}^{n} \alpha_i^2\right)\sigma^2$$

Next suppose the model relating $Y$ to $\{y_i\}$ is nonlinear, but the errors are small and independent of one another. Then a change in $Y$ is related to changes in $y_i$ by

$$dY = \frac{\partial Y}{\partial y_1} dy_1 + \frac{\partial Y}{\partial y_2} dy_2 + \cdots$$

If the changes are indeed small, then the partial derivatives are constant among all the samples. Then the expected value of the change $E(dY)$ is zero. The variances are related by the following equation (Box et al., 2005):

$$\sigma^2(dY) = \sum_{i=1}^{N} \left(\frac{\partial Y}{\partial y_i}\right)^2 \sigma_i^2$$

Thus, the variance of the desired quantity $Y$ can be found. This gives an independent estimate of the errors in measuring the quantity $Y$ from the errors in measuring each variable it depends upon.

***Example*** Suppose one wants to measure the thermal conductivity of a solid $k$. To do this, one needs to measure the heat flux $q$, the thickness of the sample $d$, and the temperature difference across the sample $\Delta T$. Each measurement has some error. The heat flux $q$ may be the rate of electric heat input $\dot{Q}$ divided by the area $A$, and both quantities are measured to some tolerance. The thickness of the sample is measured with some accuracy, and the temperatures are probably measured with a thermocouple to some accuracy. These measurements are combined, however, to obtain the thermal conductivity, and it is desired to know the error in the thermal conductivity. The formula is

$$k = \frac{d}{A\Delta T}\dot{Q}$$

The variance in the thermal conductivity is then

$$\sigma_k^2 = \left(\frac{k}{d}\right)^2 \sigma_d^2 + \left(\frac{k}{\dot{Q}}\right)^2 \sigma_Q^2 + \left(\frac{k}{A}\right)^2 \sigma_A^2 + \left(\frac{k}{\Delta T}\right)^2 \sigma_{\Delta T}^2$$

## ANALYSIS OF VARIANCE (ANOVA) AND FACTORIAL DESIGN OF EXPERIMENTS

Statistically designed experiments consider the effect of primary variables, but they also consider the effect of extraneous variables and the interactions between variables, and they include a measure of the random error. Primary variables are those whose effect you wish to determine. These variables can be quantitative or qualitative. The quantitative variables are ones you may fit to a model in order to determine the model parameters (see the section Least Squares). Qualitative variables are ones whose effect you wish to know, but you do not try to quantify that effect other than to assign possible errors or magnitudes. Qualitative variables can be further subdivided into Type I variables, whose effect you wish to determine directly, and Type II variables, which contribute to the performance variability and whose effect you wish to average out. For example, if you are studying the effect of several catalysts on yield in a chemical reactor, each different type of catalyst would be a Type I variable because you would like to know the effect of each. However, each time the catalyst is prepared, the results are slightly different due to random variations; thus, you may have several batches of what purports to be the same catalyst. The variability between batches is a Type II variable. Since the ultimate use will require using different batches, you would like to know the overall effect including that variation, since knowing precisely the results from one batch of one catalyst might not be representative of the results obtained from all batches of the same catalyst. A randomized block design, incomplete block design, or Latin square design (Box et al., 2005), for example, all keep the effect of experimental error in the blocked variables from influencing the effect of the primary variables. Other uncontrolled variables are accounted for by introducing randomization in parts of the experimental design. To study all variables and their interaction requires a factorial design, involving all possible combinations of each variable, or a fractional factorial design, involving only a selected set. Statistical techniques are then used to determine which are the important variables, what are the important interactions, and what the error is in estimating these effects. The discussion here is only a brief overview of the excellent book by Box et al. (2005).

**ANOVA** Suppose we have two methods of preparing some product and we wish to see which treatment is better. When there are only two treatments, then the sampling analysis discussed in the section Two-Population Test of Hypothesis for Means can be used to deduce if the means of the two treatments differ significantly. When there are more treatments, the analysis is more detailed. The goal is to see if the treatments differ significantly from each other; that is, whether their means are different when the samples have the same variance. The hypothesis is that the treatments are all the same, and the null hypothesis is that they are different. The statistical validity of the hypothesis is determined by an analysis of variance.

***Example*** Suppose the experimental results of the four treatments are arranged as shown in the table: several measurements for each treatment. Are the treatments significantly different from each other? The data are a modified table from Box et al. (2005).

**Analysis of Variance: Estimating the Variance of Four Treatments**

| | Treatment | | | |
|---|---|---|---|---|
| | 1 | 2 | 3 | 4 |
| | 63 | 65 | 71 | 62 |
| | 59 | 63 | 68 | 61 |
| | 63 | 71 | 68 | 63 |
| | | 64 | 68 | 56 |
| | | 67 | | 64 |
| | | | | 56 |
| Treatment average | 61.67 | 66.00 | 68.75 | 60.33 |
| Grand average | | 64.00 | | |
| Sample variance | 5.333 | 10.000 | 2.250 | 12.267 |

The data for $k = 4$ treatments is arranged in the table. For each treatment, there are $n_t$ experiments, and the outcome of the $i$th experiment with treatment $t$ is called $y_{ti}$. Compute the treatment average

$$\bar{y}_t = \frac{\sum_{i=1}^{n_t} y_{ti}}{n_t}$$

Also compute the grand average

$$\bar{y} = \frac{\sum_{t=1}^{k} n_t \bar{y}_t}{N}, N = \sum_{t=1}^{k} n_t$$

Next compute the sum of squares of deviations from the average within the $t$th treatment

$$S_t = \sum_{i=1}^{n_t} (y_{ti} - \bar{y}_t)^2$$

Since each treatment has $n_t$ experiments, the number of degrees of freedom is $n_t - 1$. Then the sample variances are

$$s_t^2 = \frac{S_t}{n_t - 1}$$

The within-treatment sum of squares is

$$S_R = \sum_{t=1}^{k} S_t$$

and the within-treatment sample variance is

$$s_R^2 = \frac{S_R}{N - k} = 8.482$$

Now, if there is no difference between treatments, a second estimate of $\sigma^2$ could be obtained by calculating the variation of the treatment averages about the grand average. Thus compute the between-treatment mean square

$$S_T = \sum_{t=1}^{k} n_t (\bar{y}_t - \bar{y})^2, \quad s_T^2 = \frac{S_T}{k-1} = 69.08$$

Basically the test for whether the hypothesis is true hinges on a comparison of the within-treatment estimate $s_R^2$ (with $\nu_R = N - k$ degrees of freedom) with the between-treatment estimate $s_T^2$ (with $\nu_T = k - 1$ degrees of freedom). The ratio of variances $s_T^2/s_R^2 = 8.145$. The test is made based on the $F$ distribution for $\nu_T$ and $\nu_R$ degrees of freedom, FINV($\alpha$/2, $\nu_T$, $\nu_R$) = $f$ (the order of the degrees of freedom is important) where

$$\text{Probability}\,[1/f \le s_T^2/s_R^2 \le f] = \alpha$$

Here FINV(0.05, 3, 14) = 3.344; the rejection region is $F > 3.344$. Since the ratio of variances is 8.145 and larger than 3.344, the hypothesis is rejected; the four treatments are not statistically the same at the 10 percent level. Alternatively, $F = 8.145$ at a $p$ value of about 0.002, and the null hypothesis is rejected.

Randomized blocking can be used to eliminate the effect of some variable whose effect is of no interest, such as the batch-to-batch variation of the catalysts in the chemical reactor example. See Box et al., 2005 for details.

**Factorial Design** To measure the effects of variables on a single outcome, a factorial design is appropriate. In a two-level factorial design, each variable is considered at two levels only, a high and low value, often designated as a + and −. The two-level factorial design is useful for indicating trends and showing interactions, and it is also the basis for a fractional factorial design. As an example, consider a $2^3$ factorial design with 3 variables and 2 levels for each. The experiments are indicated in the factorial design table.

**Two-Level Factorial Design with Three Variables**

| | Variable | | |
|---|---|---|---|
| Run | 1 | 2 | 3 |
| 1 | − | − | − |
| 2 | + | − | − |
| 3 | − | + | − |
| 4 | + | + | − |
| 5 | − | − | + |
| 6 | + | − | + |
| 7 | − | + | + |
| 8 | + | + | + |

The main effects are calculated by calculating the difference between results from all high values of a variable and all low values of a variable; the result is divided by the number of experiments at each level. For example, for the first variable

$$\text{Effect of variable 1} = \frac{(y_2 + y_4 + y_6 + y_8) - (y_1 + y_3 + y_5 + y_7)}{4}$$

Note that all observations are being used to supply information on each of the main effects, and each effect is determined with the precision of a fourfold replicated difference. The advantage of a one-at-a-time experiment is the gain in precision if the variables are additive and the measure of nonadditivity if it occurs (Box et al., 2005).

Interaction effects between variables 1 and 2 are obtained by calculating the difference between the results obtained with the high and low value of 1 at the low value of 2 compared with the results obtained with the high and low value of 1 at the high value of 2. The 12 interaction is

$$12\text{-interaction} = \frac{(y_4 - y_3 + y_8 - y_7) - (y_2 - y_1 + y_6 - y_5)}{2}$$

The key step is to determine the errors associated with the effect of each variable and each interaction so that the significance can be determined. Thus, standard errors need to be assigned. This can be done by repeating the experiments, but it can also be done by using higher-order interactions (such as 123 interactions in a $2^4$ factorial design). These are assumed negligible in their effect on the mean but can be used to estimate the standard error. Then calculated effects that are large compared with the standard error are considered important, while those that are small compared with the standard error are considered to be due to random variations and are unimportant.

In a fractional factorial design, one does only part of the possible experiments. When there are $k$ variables, a factorial design requires $2^k$ experiments. When $k$ is large, the number of experiments can be large; for $k = 5$, $2^5 = 32$. For a $k$ this large, Box et al. (2005) do a fractional factorial design. In the fractional factorial design with $k = 5$, only 16 experiments are done. Cropley (1978) gives an example of how to combine heuristics and statistical arguments in application to kinetics mechanisms in chemical engineering.

## DIMENSIONAL ANALYSIS

Dimensional analysis allows the engineer to reduce the number of variables that must be considered to model experiments or correlate data. Consider a simple example in which two variables $F_1$ and $F_2$ have the units of force, and two additional variables $L_1$ and $L_2$ have the units of length. Rather than having to deduce the relation of one variable on the other three, $F_1 = \text{fn}(F_2, L_1, L_2)$, dimensional analysis can be used to show that the relation must be of the form $F_1/F_2 = \text{fn}(L_1/L_2)$. Thus considerable experimentation is saved. Historically, dimensional analysis can be done using the Rayleigh method or the Buckingham pi method. This brief discussion is equivalent to the Buckingham pi method but uses concepts from linear algebra; see Amundson, N. R., *Mathematical Methods in Chemical Engineering*, Prentice-Hall, Englewood Cliffs, N.J., 1966, p. 54, for further information.

The general problem is posed as finding the minimum number of variables necessary to define the relationship between $n$ variables. Let $\{Q_i\}$ represent a set of fundamental units, such as length, time, force, and so on. Let $[P_i]$ represent the dimensions of a physical quantity $P_i$; there are $n$ physical quantities. Then form the matrix $\alpha_{ij}$

| | $[P_1]$ | $[P_2]$ | … | $[P_n]$ |
|---|---|---|---|---|
| $Q_1$ | $\alpha_{11}$ | $\alpha_{12}$ | … | $\alpha_{1n}$ |
| $Q_2$ | $\alpha_{21}$ | $\alpha_{22}$ | … | $\alpha_{2n}$ |
| … | | | | |
| $Q_m$ | $\alpha_{m1}$ | $\alpha_{m2}$ | … | $\alpha_{mn}$ |

in which the entries are the number of times each fundamental unit appears in the dimensions $[P_i]$. The dimensions can then be expressed as follows:

$$[P_i] = Q_1^{\alpha_{1i}} Q_2^{\alpha_{2i}} \cdots Q_m^{\alpha_{mi}}$$

Let $m$ be the rank of the $\alpha$ matrix. Then $p = n - m$ is the number of dimensionless groups that can be formed. One can choose $m$ variables $\{P_i\}$ to be the basis and express the other $p$ variables in terms of them, giving $p$ dimensionless quantities.

***Example: Buckingham Pi Method—Heat-Transfer Film Coefficient*** It is desired to determine a complete set of dimensionless groups with which to correlate experimental data on the film coefficient of heat transfer between the walls of a straight conduit with circular cross section and a fluid flowing in that conduit. The variables and the dimensional constant believed to be involved and their dimensions in the engineering system are given below:

Film coefficient $= h = F/L\theta T$
Conduit internal diameter $= D = L$
Fluid linear velocity $= V = L/\theta$
Fluid density $= \rho = M/L^3$
Fluid absolute viscosity $= \mu = M/L\theta$
Fluid thermal conductivity $= k = F/\theta T$
Fluid specific heat $= c_p = FL/MT$
Dimensional constant $= g_c = ML/F\theta^2$

The matrix $\alpha$ in this case is as follows:

| | | $[P_i]$ | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | | $h$ | $D$ | $V$ | $\rho$ | $\mu$ | $k$ | $C_p$ | $g_c$ |
| $Q_j$ | $F$ | 1 | 0 | 0 | 0 | 0 | 1 | 1 | −1 |
| | $M$ | 0 | 0 | 0 | 1 | 1 | 0 | −1 | 1 |
| | $L$ | −1 | 1 | 1 | −3 | −1 | 0 | 1 | 1 |
| | $\theta$ | −1 | 0 | −1 | 0 | −1 | −1 | 0 | −2 |
| | $T$ | −1 | 0 | 0 | 0 | 0 | −1 | −1 | 0 |

Here $m \le 5$, $n = 8$, and $p \ge 3$. Choose $D$, $V$, $\mu$, $k$, and $g_c$ as the primary variables. By examining the $5 \times 5$ matrix associated with those variables, we can see that its determinant is not zero, so the rank of the matrix is $m = 5$; thus, $p = 3$. These variables are thus a possible basis set. The dimensions of the other three variables $h$, $\rho$, and $C_p$ must be defined in terms of the primary variables. This can be done by inspection, although linear algebra can be used, too.

$$[h] = D^{-1}k^{+1};\ \text{thus}\ \frac{h}{D^{-1}k} = \frac{hD}{k}\ \text{is a dimensionless group}$$

$$[\rho] = \mu^{1}V^{-1}D^{-1};\ \text{thus}\ \frac{\rho}{\mu^{1}V^{-1}D^{-1}} = \frac{\rho VD}{\mu}\ \text{is a dimensionless group}$$

$$[C_p] = k^{1}\mu^{-1};\ \text{thus}\ \frac{C_p}{k^{+1}\mu^{-1}} = \frac{C_p\mu}{k}\ \text{is a dimensionless group}$$

Thus, the dimensionless groups are

$$\frac{[P_i]}{Q_1^{\alpha 1i}Q_1^{\alpha 2i}\cdots Q_m^{\alpha mi}}: \frac{hD}{k}, \frac{\rho VD}{\mu}, \frac{C_p\mu}{k}$$

The dimensionless group $hD/k$ is called the Nusselt number, $N_{Nu}$, and the group $C_p\mu/k$ is the Prandtl number, $N_{Pr}$. The group $DV\rho/\mu$ is the familiar Reynolds number, $N_{Re}$, encountered in fluid-friction problems. These three dimensionless groups are frequently used in heat-transfer-film-coefficient correlations. Functionally, their relation may be expressed as

$$\phi(N_{Nu}, N_{Pr}, N_{Re}) = 0 \qquad (3\text{-}100)$$

or as

$$N_{Nu} = \phi_1(N_{Pr}, N_{Re})$$

It has been found that these dimensionless groups may be correlated well by an equation of the type

$$hD/k = K(c_p\mu/k)^a(DV\rho/\mu)^b$$

in which $K$, $a$, and $b$ are experimentally determined dimensionless constants. However, any other type of algebraic expression or perhaps simply a graphical relation among these three groups that accurately fits the experimental data would be an equally valid manner of expressing Eq. (3-100).

Naturally, other dimensionless groups might have been obtained in the example by employing a different set of five repeating quantities that would not form a dimensionless group among themselves. Some of these groups may be found among those presented in Table 3-5. Such a complete set of three dimensionless groups might consist of Stanton, Reynolds, and Prandtl numbers or of Stanton, Peclet, and Prandtl numbers. Also such a complete set different from that obtained in the preceding example will result from a multiplication of appropriate powers of the Nusselt, Prandtl, and Reynolds numbers. For such a set to be complete, however, it must satisfy the condition that each of the three dimensionless groups is independent of the other two.

**TABLE 3-5 Dimensionless Groups in the Engineering System of Dimensions**

| | | |
|---|---|---|
| Biot number | $N_{Bi}$ | $hL/k$ |
| Condensation number | $N_{Co}$ | $(h/k)(\mu^2/\rho^2 g)^{1/3}$ |
| Number used in condensation of vapors | $N_{Cv}$ | $L^3\rho^2 g\lambda/(k\mu\,\Delta t)$ |
| Euler number | $N_{Eu}$ | $g_c(-dp)/\rho V^2$ |
| Fourier number | $N_{Fo}$ | $k\,\theta/\rho cL^2$ |
| Froude number | $N_{Fr}$ | $V^2/Lg$ |
| Graetz number | $N_{Gz}$ | $wc/kL$ |
| Grashof number | $N_{Gr}$ | $L^3\rho^2\beta g\,\Delta T/\mu^2$ |
| Mach number | $N_{Ma}$ | $V/V_a$ |
| Nusselt number | $N_{Nu}$ | $hD/k$ |
| Peclet number | $N_{Pe}$ | $DV\rho c/k$ |
| Prandtl number | $N_{Pr}$ | $c\mu/k$ |
| Reynolds number | $N_{Re}$ | $DV\rho/\mu$ |
| Schmidt number | $N_{Sc}$ | $\mu/\rho D_u$ |
| Stanton number | $N_{St}$ | $h/cV\rho$ |
| Weber number | $Nw_e$ | $LV^2\rho/\sigma g_c$ |

# PROCESS SIMULATION

Widagdo, *Product and Process Design Principles: Synthesis, Analysis, and Evaluation,* 3d ed., Wiley, New York, 2009.

## CLASSIFICATION

*Process simulation* refers to the activity in which mathematical systems of chemical processes and refineries are modeled with equations, usually on the computer. The usual distinction must be made between steady-state models and transient models, following the ideas presented in the introduction to this section. In a chemical process, of course, the process is nearly always in a transient mode, at some level of precision, but when the time-dependent fluctuations are below some value, a steady-state model can be formulated. This subsection presents briefly the ideas behind steady-state process simulation (also called *flowsheeting*), which are embodied in commercial codes. The transient simulations are important

for designing the start-up of plants and are especially useful for the operation of chemical plants.

## THERMODYNAMICS

The most important aspect of the simulation is that the thermodynamic data of the chemicals be modeled correctly. It is necessary to decide what equation of state to use for the vapor phase (ideal gas, Soave-Redlich-Kwong, Peng-Robinson, etc.) and what model to use for liquid activity coefficients [ideal solutions, solubility parameters, Wilson equation, nonrandom two liquid (NRTL), UNIFAC, etc.]. See Sec. 4, Thermodynamics, and Sandler (2015). It is necessary to consider mixtures of chemicals, and the interaction parameters must be predictable. The best case is to determine them from data, and the next-best case is to use correlations based on the molecular weight, structure, and normal boiling point. To validate the model, the computer results of vapor-liquid equilibria could be checked against experimental data to ensure their validity before the data are used in more complicated computer calculations.

## PROCESS MODULES OR BLOCKS

At the first level of detail, it is not necessary to know the internal parameters for all the units, since what is desired is just the overall performance. For example, in a heat exchanger design, it suffices to know the heat duty, total area, and temperatures of the output streams; the details such as the percentage baffle cut, tube layout, or baffle spacing can be specified later when the details of the proposed plant are better defined. It is important to realize the level of detail modeled by a commercial computer program. For example, a chemical reactor could be modeled as an equilibrium reactor, in which the input stream is brought to a new temperature and pressure and the output stream is in chemical equilibrium at those new conditions. Or, it may suffice to simply specify the conversion, and the computer program will calculate the outlet compositions. In these cases, the model equations are algebraic ones, and you do not learn the volume of the reactor. A more complicated reactor might be a stirred tank reactor, and then you would have to specify kinetic information so that the simulation can be made, and one output would be either the volume of the reactor or the conversion possible in a volume you specify. Such models are also composed of sets of algebraic equations. A plug flow reactor is modeled as a set of ordinary differential equations as initial-value problems, and the computer program must use numerical methods to integrate them. See Numerical Solution of Ordinary Differential Equations as Initial-Value Problems. Kinetic information must be specified, and one learns the conversion possible in a given reactor volume, or, in some cases, the volume reactor that will achieve a given conversion. The simulation engineer determines what a reactor of a given volume will do for the specified kinetics and reactor volume. The design engineer, however, wants to achieve a certain result and wants to know the volume necessary. Simulation packages are best suited for the simulation engineer, and the design engineer must vary specifications to achieve the desired output.

Distillation simulations can be based on shortcut methods, using correlations based on experience, but more rigorous methods involve solving for the vapor-liquid equilibrium on each tray. The shortcut method uses relatively simple equations, and the rigorous method requires solution of huge sets of nonlinear equations. The computation time of the latter is significant, but the rigorous method may be necessary when the chemicals you wish to distill are not well represented in the correlations. Then the designer must specify the number of trays and determine the separation that is possible. This, of course, is not what she or he wants: the number of trays needed to achieve a specified objective. Thus, again, some adjustment of parameters is necessary in a design situation.

Absorption columns can be modeled in a plate-to-plate fashion (even if it is a packed bed) or as a packed bed. The former model is a set of nonlinear algebraic equations, and the latter model is an ordinary differential equation. Since streams enter at both ends, the differential equation is a two-point boundary-value problem, and numerical methods are used (see Numerical Solution of Ordinary Differential Equations as Initial-Value Problems).

If one wants to model a process unit that has significant flow variation, and possibly some concentration distributions as well, one can consider using computational fluid dynamics (CFD) to do so. These calculations are very time-consuming, however, so that they are often left until the mechanical design of the unit. The exception would occur when the flow variation and concentration distribution had a significant effect on the output of the unit so that mass and energy balances couldn't be made without it.

The process units are described in greater detail in other sections of the Handbook. In each case, parameters of the unit are specified (size, temperature, pressure, area, and so forth). In addition, in a computer simulation, the computer program must be able to take any input to the unit and calculate the output for those parameters. Since the entire calculation is done iteratively, there is no assurance that the input stream is a "reasonable" one, so that the computer codes must be written to give some sort of output even when the input stream is unreasonable. This difficulty makes the iterative process even more complicated.

## PROCESS TOPOLOGY

A chemical process usually consists of a series of units, such as distillation towers, reactors, and so forth (see Fig. 3-65). If the feed to the process is known and the operating parameters of the units are specified by the user, then one can begin with the first unit, take the process input, calculate the unit output, carry that output to the input of the next unit, and continue the process. However, if the process involves a recycle stream, as nearly all chemical processes do, then when the calculation is begun, it is discovered that the recycle stream is unknown. This situation leads to an iterative process: the flow rates, temperature, and pressure of the unknown recycle stream are guessed, and the calculations proceed as before. When one reaches the end of the process, where the recycle stream is formed to return to the first unit, it is necessary to check to see if the recycle stream is the same as assumed. If not, an iterative procedure must be used to cause convergence. Possible techniques are described in Numerical Solutions of Nonlinear Equations in One Variable and Numerical Solution of Simultaneous Equations. The direct method (or successive substitution method) just involves calculating around the process over and over. The Wegstein method accelerates convergence for a single variable, and Broyden's method does the same for multiple variables. The Newton method can be used provided there is some way to calculate the derivatives (possibly by using a numerical derivative). Optimization methods can also be used (see Optimization in this section). In the description given here, the recycle stream is called the *tear stream*: this is the stream that must be guessed to begin the calculation. When there are multiple recycle streams, convergence is even more difficult, since more guesses are necessary, and what happens in one recycle stream may cause difficulties for the guesses in other recycle streams. See Seader (1985) and Mah (1990).

It is sometimes desired to control some stream by varying an operating parameter. For example, in a reaction/separation system, if there is an impurity that must be purged, a common objective is to set the purge fraction so that the impurity concentration into the reactor is kept at some moderate value. Commercial packages contain procedures for doing this, using what are often called *control blocks*. However, this can also make the solution more difficult to find.

An alternative method of solving the equations is to solve them as simultaneous equations. In that case, one can specify the design variables and the desired specifications and let the computer figure out the process parameters that will achieve those objectives. It is possible to overspecify the system or to give impossible conditions. However, the biggest drawback to

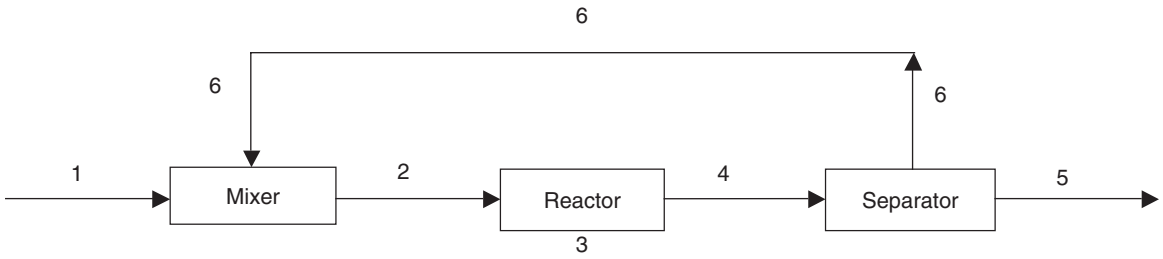

**FIG. 3-65** Prototype flowsheet.

this method of simulation is that large sets (tens of thousands) of nonlinear algebraic equations must be solved simultaneously. As computers become faster, this is less of an impediment, provided efficient software is available.

Dynamic simulations are also possible, and these require solving differential equations, sometimes with algebraic constraints. If some parts of the process change extremely quickly when there is a disturbance, that part of the process may be modeled in the steady state for the disturbance at any instant. Such situations are called *stiff*, and the methods for them are discussed in Numerical Solution of Ordinary Differential Equations as Initial-Value Problems. It must be realized, though, that a dynamic calculation can also be time-consuming, and sometimes the allowable units are lumped-parameter models that are simplifications of the equations used for the steady-state analysis. Thus, as always, the assumptions need to be examined critically before accepting the computer results. The dynamic simulators can also be used to simulate operations with the objective to maintain purity and standards of the product.

## COMMERCIAL PACKAGES

Computer programs are provided by many companies, and they range from empirical models to deterministic models. For example, if one wanted to know the pressure drop in a piping network, one would normally use a correlation for friction factor as a function of Reynolds number to calculate the pressure drop in each segment. A sophisticated turbulence model of fluid flow is not needed in that case. As computers become faster, however, more and more models are deterministic. Since the commercial codes have been used by many customers, the data in them have been verified, but possibly not for the case you want to solve. Thus, you must test the thermodynamics correlations carefully. In 2015, there were a number of computer codes, but the company names change constantly. Here are a few of them for process simulation: Aspen Tech (Aspen Plus), Chemstations (CHEMCAD), Honeywell (UniSim Design), ProSim (ProSimPlus), and Pro II. The CAPE-OPEN project is working to make details as transferable as possible.

## Nomenclature and Units

Correlation- and application-specific symbols are not shown.

| Symbol | Definition | SI units | U.S. Customary System units |
|---|---|---|---|
| $A$ | Molar (or unit-mass) Helmholtz energy† or dimensionless equation of state parameter | J/mol [J/kg] | Btu/lb·mol [Btu/lbm] |
| $A_x$ | Cross-sectional area in flow | $m^2$ | $ft^2$ |
| $a_i$ | Activity of species $i$ in solution | Dimensionless | Dimensionless |
| $B$ | 2d virial coefficient or dimensionless equation of state parameter | $cm^3$/mol | $cm^3$/mol |
| $B_{ij}$ | Interaction 2d virial coefficient | $cm^3$/mol | $cm^3$/mol |
| $C_P$ | Heat capacity at constant pressure | J/(mol·K) | Btu/(lb·mol·°R) |
| $C_V$ | Heat capacity at constant volume | J/(mol·K) | Btu/(lb·mol·°R) |
| $f_i$ | Fugacity of pure species $i$ | kPa | psi |
| $\hat{f}_i$ | Fugacity of species $i$ in solution | kPa | psi |
| $G$ | Molar (or unit-mass) Gibbs energy† | J/mol [J/kg] | Btu/(lb·mol) [Btu/lbm] |
| $g$ | Acceleration of gravity | $m/s^2$ | $ft/s^2$ |
| $H$ | Molar (or unit-mass) enthalpy† | J/mol [J/kg] | Btu/(lb·mol) [Btu/lbm] |
| $h_i$ | Henry's volatility constant for solute species at $T$ and $P°$ | kPa | psi |
| $K_i$ | Equilibrium $K$ value, $y_i/x_i$ | Dimensionless | Dimensionless |
| $K_{a,j}$ | Equilibrium constant for chemical reaction $j$ | Dimensionless | Dimensionless |
| $k_{H,i}$ | Henry's solubility constant for solute species $i$ in molal units | mol/kg·kPa | mol/kg·psi |
| $M$ | Molar or unit-mass solution property† ($A$, $G$, $H$, $S$, $U$, $V$) | | |
| $M_i$ | Molar or unit-mass pure-species property† ($A_i$, $G_i$, $H_i$, $S_i$, $U_i$, $V_i$) | | |
| $\overline{M}_i$ | Partial property of species $i$ in solution ($\overline{A}_i$, $\overline{G}_i$, $\overline{H}_i$, $\overline{S}_i$, $\overline{U}_i$, $\overline{V}_i$) | | |
| $M^{dep}$ | Departure thermodynamic property† ($A^{dep}$, $G^{dep}$, $H^{dep}$, $S^{dep}$, $U^{dep}$, $V^{dep}$) | | |
| $M^E$ | Excess thermodynamic property† ($A^E$, $G^E$, $H^E$, $S^E$, $U^E$, $V^E$) | | |
| $\overline{M}_i^E$ | Partial molar excess thermodynamic property | | |
| $\Delta M$ | Property change of mixing† ($\Delta A$, $\Delta G$, $\Delta H$, $\Delta S$, $\Delta U$, $\Delta V$) | | |
| $\Delta M_j°$ | Standard property change of reaction $j$ ($\Delta G_j°$, $\Delta H_j°$, $\Delta C_{Pj}°$) | | |
| $m$ | Mass | kg | lbm |
| $\dot{m}$ | Mass flow rate | kg/s | lbm/s |
| $n$ | Number of moles | | |
| $\dot{n}$ | Molar flow rate | | |
| $n_i$ | Number of moles of species $i$ | | |
| $P$ | Pressure | kPa | psi |
| $P_i^{sat}$ | Saturation or vapor pressure of species $i$ | kPa | psi |
| $q$ | Quality (vapor fraction) | Dimensionless | Dimensionless |
| $Q$ | Heat per mole or mass† | J/mol [J/kg] | Btu/lb·mol [Btu/lbm] |
| $\dot{Q}$ | Rate of heat transfer per mole or mass† | J/(mol·s) [J/kg·s] | Btu/(lb·mol·s) [Btu/(lbm·s)] |
| $R$ | Universal gas constant | J/(mol·K) | Btu/(lb·mol·°R) |
| $S$ | Molar (or unit-mass) entropy† | J/(mol·K) [J/(kg·K)] | Btu/(lb·mol·°R) [Btu/(lbm·°R)] |
| $\dot{S}_{gen}$ | Rate of entropy generation per mole or unit mass† | J/(K·mol·s) [J/(K·kg·s)] | Btu/(lb·mol·°R·s) [Btu/(lbm·°R·s)] |
| $T$ | Temperature | K | °R |
| $T_c$ | Critical temperature | K | °R |
| $U$ | Molar (or unit-mass) internal energy† | J/mol [J/kg] | Btu/(lb·mol) [Btu/lbm] |
| $v$ | Fluid velocity | m/s | ft/s |
| $V$ | Molar (or unit-mass) volume† | $m^3$/mol [$m^3$/kg] | $ft^3$/(lb·mol) [$ft^3$/lbm] |
| $W$ | Work per mole or unit mass† | J/mol [J/kg] | Btu/lb·mol [Btu/lbm] |
| $\dot{W}_s$ | Shaft work for flow process† | J/mol [J/kg] | Btu/lb·mol [Btu/lbm] |
| $\dot{W}_S$ | Shaft power for flow process† | J/(mol·s) [J/(kg·s] | Btu/(lb·mol·s) [Btu/(lbm·s)] |
| $x_i$ | Mole fraction in general | | |
| $x_i$ | Mole fraction of species $i$ in liquid phase | | |
| $y_i$ | Mole fraction of species $i$ in vapor phase | | |
| $Z$ | Compressibility factor | Dimensionless | Dimensionless |
| $z$ | Elevation above a datum level | m | ft |

### Superscripts

| | |
|---|---|
| cond | Condensed phase, e.g. liquid or solid |
| dep | Departure thermodynamic property |
| $E$ | Excess thermodynamic property |
| id | Value for an ideal solution |
| ig | Value for an ideal gas |
| $L$ | Liquid phase |
| $V$ | Vapor phase |
| vap | Phase transition, liquid to vapor |
| ∞ | Value at infinite dilution |

### Subscripts

| | |
|---|---|
| $c$ | Value for the critical state |
| cv | Control volume |
| fs | Flowing streams |
| $n$ | Normal boiling point |
| $r$ | Reduced value |
| $R$ | Reference state |

### Greek Letters

| | | | |
|---|---|---|---|
| α, β | As superscripts, identify phases | | |
| β | Volume expansivity | $K^{-1}$ | $°R^{-1}$ |
| $\varepsilon_j$ | Reaction coordinate for reaction $j$ | mol | lb·mol |
| γ | Heat capacity ratio $C_P/C_V$ | Dimensionless | Dimensionless |
| $\gamma_i$ | Activity coefficient of species $i$ in solution for the Lewis-Randall rule, a superscript * denotes Henry's law activity coefficient | Dimensionless | Dimensionless |
| κ | Isothermal compressibility | $kPa^{-1}$ | $psi^{-1}$ |
| $\mu_i$ | Chemical potential of species $i$ | J/mol | Btu/(lb·mol) |
| $\nu_{i,j}$ | Stoichiometric number of species $i$ in reaction $j$ | Dimensionless | Dimensionless |
| ρ | Molar or mass density | mol/$m^3$ [kg/$m^3$] | lb·mol/$ft^3$ [lbm/$ft^3$] |
| $\phi_i$ | Fugacity coefficient of pure species $i$ | Dimensionless | Dimensionless |
| $\hat{\phi}_i$ | Fugacity coefficient of species $i$ in solution | Dimensionless | Dimensionless |
| ω | Acentric factor | Dimensionless | Dimensionless |

†When underlined, denotes extensive thermodynamic property [e.g., energy] or total work or heat [e.g., energy].

# INTRODUCTION

Thermodynamics is the branch of science that deals with energy transformation and the state of equilibrium in macroscopic systems. The laws of thermodynamics are shown by experience to apply to all such transformations. The first law states that energy can take many forms, but it cannot be created or destroyed (except that nuclear reactions may contribute components outside the norm). The second law concerns the distribution of the energy and of the material components comprising a system, traditionally described in terms of the order or disorder of the system. It states that maintaining a nonequilibrium or unnaturally ordered state requires work. The systematic analysis of these two laws leads to profound insights pervading chemistry, physics, and biology, especially when combined with molecular insights through statistical thermodynamics. In the context of chemical engineering, it is important to include one additional conservation law, the material balance. Similar to energy, mass is neither created nor destroyed in (nonnuclear) systems. The material balance is not technically a law of thermodynamics, but it is necessary to fully characterize the equilibrium systems that are central to thermodynamics.

While the first law of thermodynamics is the basis for the energy balance, the second law is the basis for the concept of entropy. The second law states that the entropy of the universe (defined in terms of reversible heat flow divided by absolute temperature) must increase through the conduct of any practical process, meaning that the entropy of individual subsystems may increase or decrease but the sum of entropy changes across all subsystems and surroundings must increase. As a consequence, thermal energy spontaneously flows from a hotter body to a cooler one, and statistical mechanics indicates a general tendency for a system to move toward spatial homogeneity.

Energy, on the other hand, has a tendency to pull things together. Molecules are attracted to one another as evidenced by the energy of vaporization required to increase the intermolecular distances when converting liquid to vapor. Thus, nature exhibits a competition between energetic and entropic driving forces when temperature and pressure are fixed. When these competing driving forces are perfectly balanced, the situation is described as *equilibrium*. A simple form of equilibrium is evidenced by a vapor in equilibrium with a liquid at its boiling point. Entropy is driving the molecules toward the vapor while energy is pulling molecules into the liquid. At a given temperature for a pure fluid, the rate of evaporation equals the rate of condensation at one specific pressure, comprising equilibrium, and referred to as the *saturation pressure* or *vapor pressure*.

Remarkably, the same equations and concepts of energy, entropy, and equilibrium describe all the phenomena of phase equilibria in mixtures. Tracing the energy transformations through a process is relatively straightforward. However, mixing and separation become quite complicated in the presence of aqueous streams mixed with organic compounds and possibly electrolytes, the mixing of which may form multiple solid, liquid, or vapor phases. The application of thermodynamic theory in chemical engineering practice yields models describing all these different phases at equilibrium. A deviation from the equilibrium composition is the driving force for many chemical separation processes, and many are modeled as equilibrium staged processes even when perfect equilibrium is not achieved at any particular point in the process. As a real process can only approach equilibrium (the thermodynamic limit), such an analysis allows the process designer to characterize separation difficulty and the magnitude of the opportunity for further improvement.

Another form of equilibrium in mixtures occurs when one considers that individual atoms can be rearranged within and among molecules, also known as *chemical reaction equilibrium*. By controlling the components in a mixture and through the use of catalysts that favor selected pathways, chemical engineers can synthesize desirable products from crude raw materials on a very large scale. Each step in the synthesis process is constrained by reaction thermodynamics. The desired products can be formed only if the equilibrium constant is favorable.

The mass, energy, and entropy balances of multicomponent, multiphase, reacting systems at thermodynamic equilibrium comprise significant coverage of the chemical engineering discipline. The rates at which systems move toward equilibrium comprise another fundamental field of study, and often an analysis of process performance requires an assessment as to which phenomenon is the dominant factor controlling performance—the equilibrium state or the rate of mass transfer or chemical reaction exhibited by a system in moving toward that state ( for fundamentals, see Sections 5-7). Identifying and addressing key equilibrium limitations and/or rate-limiting resistances is a fundamental approach to improving process designs.

For most chemical engineers, a process simulator is the primary interface for engaging thermodynamics. The intent of this section is to expose the thermodynamics while simplifying the computational rigor, with the emphasis placed on nonelectrolyte systems.

## ELEMENTARY VARIABLES AND DEFINITIONS

It is necessary to define several common quantities before developing the key equations to be applied in further analysis.

**Mass $m$** *Mass* is the magnitude of the interaction of a physical body in response to an external force. (We ignore relativistic influences in this discussion.) Commonly, the external force is gravity, and the mass is given by the weight at sea level. The mass also describes the resistance of the body to acceleration in the presence of any force, as in $F = ma$.

**System or Control Volume** A region in space that identifies the portion of the universe under consideration at a particular juncture.

**Density ρ** The mass or moles per unit volume. We use the same symbol ρ for both mass and molar density where the units are inferred by the particular context.

**Pressure $P$** The force per unit area of molecules on the surface of their container.

**Internal Energy $U$** Energy can be transformed into many forms, such as work, heat, or kinetic energy. To be clear, it is necessary to define each form of energy distinctly. To begin, internal energy is energy inherent to a system as determined by the kinetic and intermolecular potential energy of its constituent molecules. The kinetic energy of the molecules is described below in terms of temperature. The intermolecular potential energy arises from the tendency of molecules to attract and repel one another. Attractions are responsible for the heat of vaporization. Repulsions explain why "you can't put two things in the same place at the same time." Depending on the reference state, $U$ may also include the energy of forming the molecule from the elements.

**Heat Capacity at Constant Volume $C_V$** $C_V \equiv (\partial U/\partial T)_V$ The translational and vibrational molecular energies are largely unaffected by changes in density and can be represented by the ideal gas heat capacity $C_V^{ig}$. The departures of internal energy and heat capacity from ideal gas behavior are discussed in the subsection Departure Functions from PVT Correlations.

**Enthalpy $H$** Enthalpy is a combination of internal energy, pressure, and molar volume ($H \equiv U + PV$) that is convenient for computations involving systems that are classified as "open," as defined shortly after Eq. (4-3). Note that molar volume $V$ is the reciprocal of molar density.

**Heat Capacity at Constant Pressure $C_P$** $C_P \equiv (\partial H/\partial T)_P$ Similar to the heat capacity at constant volume, the enthalpy of a fluid varies with

temperature. Empirical equations relating $C_P^{ig}$ to $T$ are available for many pure gases; a common form is either a polynomial like Eq. (4-1) or the form used by DIPPR, Eq. (4-2) (R. L. Rowley et al., *DIPPR Data Compilation of Pure Chemical Properties,* Design Institute for Physical Properties, AIChE, New York, 2006)

$$C_P^{ig} = A + BT + CT^2 + DT^3 + ET^4 \tag{4-1}$$

$$C_P^{ig} = A + B\left[\frac{C/T}{\sinh(C/T)}\right]^2 + D\left[\frac{E/T}{\cosh(E/T)}\right]^2 \tag{4-2}$$

where $A$, $B$, $C$, $D$, and $E$ are constants characteristic of the particular gas, and for Eq. (4-2) either $C$ or $D$ is zero. The DIPPR form derives from the plateaus inherent in heat capacity due to quantum energy levels [Aly, F. A., and L. L. Lee, *Fluid Phase Equilibr.* **6**: 169 (1981)].

**Expansion/Contraction Work $W_{EC}$** Work interaction of the system with the surroundings due to force at the surface of interaction through a distance is given by

$$W_{EC} = -\int P\,dV \tag{4-3}$$

**Mass, Energy, and Entropy Balances** Mass, energy, and entropy balances for any system are written with respect to a region of space known as a *system* or *control volume*, bounded by an imaginary *control surface* that separates it from the surroundings, forming a system or subsystem. This surface may follow fixed walls or be arbitrarily placed; it may be rigid or flexible. A primary step in any chemical process analysis or design is the mass balance. A system is defined as *open* if any mass crosses the system boundary. If the mass flowing into the system equals the mass flowing out, and all intensive (state) variables are invariant with time at all positions within the system, then the system is said to be at *steady state*.

# GENERAL BALANCES

## THE MASS BALANCE

Because mass is conserved, the time rate of change of mass within the control volume equals the net rate of flow of mass into the control volume (cv). The flow is positive when directed into the control volume and negative when directed out. The mass balance is expressed mathematically by

$$\sum_{\text{streams}} \dot{m}_i\,dt = d(m_{cv}) \tag{4-4}$$

The mass flow rate $\dot{m}$ can be expressed in terms of the stream velocity as

$$\dot{m}_i = (\rho v A_x)_i\,[=]\,\text{kg/s} \tag{4-5}$$

Substitution gives

$$\Delta(\rho v A_x)_{fs} = \frac{dm_{cv}}{dt} \tag{4-6}$$

The operator $\Delta$ signifies the difference between exit and entrance flows, and the subscript fs indicates that the term encompasses all flowing streams. This form of the mass balance equation is often called the *continuity equation*, an important equation in the analysis of transport processes, such as fluid flow or absorption. For the special case of *steady-state* flow, the control volume contains a constant mass of fluid, and the right-hand side of Eq. (4-6) is zero. Additional constraints for steady-state systems are discussed in the subsection The General Energy Balance.

**Mass Balances for Chemical Manufacturing Processes** Mass balances can be especially useful for multicomponent processes of multiple-unit operations. A spreadsheet calculation can suffice for many applications. A process flow diagram (PFD) is required, representing the unit operations and streams connecting them. Figure 4-1 shows a sample PFD for the dimethyl ether (DME) synthesis process ($2CH_3OH \rightarrow CH_3OCH_3 + H_2O$). Streams are numbered to provide unique identifiers. The masses in each stream are computed sequentially, depending on the unit operation.

For example, the mass of each component in stream 2 is the sum of the component mass entering from stream 1 and stream 11. Note that the flow of stream 11 may not be known at the outset, requiring an iterative process to determine its value. As another example, the mass of methanol in stream 5 is determined from the fractional conversion specification for methanol ($X$), and the masses of the other components are determined by the reaction stoichiometry. The flow rates of components in streams 8 and 9 are determined from the *split* specifications on the distillation column. The *split* is defined as the fraction of the component that exits the column as distillate. The light key component is the least volatile component that has a split fraction greater than 0.5. In consequence, any components more volatile than the light key are often assumed to exit completely in the distillate with a split of 100 percent. Similarly, the heavy key is the most volatile component that has a split fraction less than 0.5, and components less volatile than the heavy key are often assumed to exit the column with a split of 0 percent. The requisite computations to complete the mass balance are illustrated in Example 4-1.

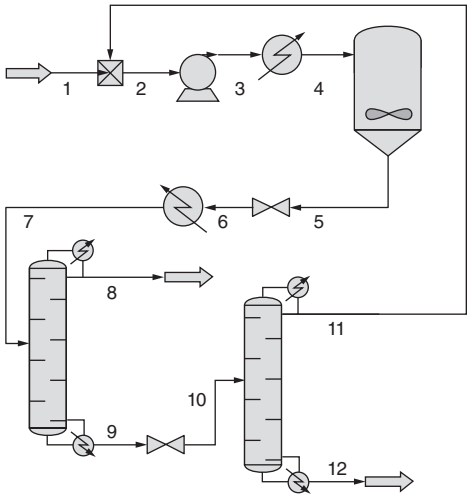

**FIG. 4-1** PFD for DME synthesis.

***Example 4-1 Mass Balances for the DME Process*** Dimethyl ether (DME) synthesis provides a simple prototype of many petrochemical processes. Ten tonnes (10,000 kg) per hour of methanol are fed at 25°C. The entire process operates at roughly 10 bar. The feed stream is mixed with the recycle stream (11), compressed and passed through a heat exchange to form stream 4 at 75°C. The methanol is 50 percent converted to DME and water at 250°C. The reactor effluent is cooled to 75°C and sent to a distillation column where 99 percent of the entering DME exits the top with 1 percent of the entering methanol and no water. This DME product stream (8) exits as liquid at 44°C while the bottom stream (9) exits at 152°C. The bottoms of the first column (9) are sent to a second column where 99 percent of the entering methanol exits the top as liquid at 136°C, along with all DME and 1 percent of the entering water, and is recycled. The bottoms of the second column exit at 179°C and are sent for wastewater treatment. Determine the masses of each component in each stream.

*Solution* A preliminary step is to write the reaction stoichiometry: $2CH_3OH \rightarrow H_2O + DME$. Since the reaction requires mass balances in terms of molar stoichiometry, we convert 10,000 kg/h to 312.11 kmol/h for stream 1. The solution for stream 2 depends on the recycle stream, for which the flow is not known at the outset. Modern spreadsheets facilitate an iterative solution for the recycle stream. Making an initial guess that 50 percent of the feed methanol (156.05 kmol/h) is being recycled in stream 11 with zero DME or $H_2O$ gives a flow of 468.16 for stream 2, as tabulated below. With 50 percent conversion of the methanol in stream 2, the tabulated flows of methanol, DME, and $H_2O$ in stream 5 are obtained. The masses are unaffected by the heat exchanger, resulting in stream 7. Applying the 99 and 1 percent splits gives the flow of streams 8 and 9. Similar computations give the flow of streams 11 and 12, at which point we note that the initial guess for stream 11 was substantially in error. At this point, the correct component masses of stream 11 could be added to stream 1 and the next iteration could proceed. Alternatively, Microsoft Excel offers an "iteration" feature that can be enabled through the calculation options. Implementing this feature leads to the mass flows (kmol/h) in the second table.

Initial guess assuming 156.05 kmol/h MeOH recycle.

## INTRODUCTORY STATE CALCULATIONS

Values of energy require calculation of fluid properties for each component relative to the reference state, plus the property state changes involved in mixing components. For changes in state properties in nonreactive systems, the reference state drops out. However, for reactive systems, the reference states must be included. The energy balances are generalized most easily by including a reference state of the elements that comprise each molecule in the stream. Most process simulators default to use a reference state of the elements in their naturally occurring state at 1 bar and 298.15 K. For expediency, we provide ideal gas properties here to introduce the energy balances and in subsection Departure Functions for PVT Relations we discuss the contributions due to nonideal gas behavior.

For an ideal gas,

$$PV = RT \quad \text{or} \quad P\underline{V} = nRT \tag{4-7}$$

Using a reference state of the elements at 298.15 K and 1 bar,

$$U^{\text{ig}} = \int_{298.15}^{T} C_V\, dT + \Delta U^f_{298.15} \tag{4-8}$$

where $\Delta U^f_{298.15}$ is the energy of formation. More typically for flow problems, the enthalpy is used. Enthalpy is defined for convenience because the combination $U + PV$ appears often:

$$H \equiv U + PV \tag{4-9}$$

The enthalpy change of an ideal gas is

$$\Delta H^{\text{ig}} = \int_{T_1}^{T_2} C_P\, dT \tag{4-10}$$

The enthalpy of an ideal gas is

$$H^{\text{ig}} = \int_{298.15}^{T} C_P\, dT + \Delta H^f_{298.15} \tag{4-11}$$

where $\Delta H^f_{298.15}$ is the enthalpy of formation. Enthalpies of formation are commonly available (c.f. Sec. 2, Tables 2-94 and 2-95). The energy of formation can be calculated from the enthalpy of formation by adapting Eq. (4-9), $\Delta U^f_{298.15} = \Delta H^f_{298.15} - \Delta(PV)$, where the $PV$ term is on the basis of 1 mol of the substance being formed. The $PV$ term is typically negligible for condensed phases (e.g., solid carbon), and the value is $RT$ for each mole of ideal gas, so the correction term can typically be written $\Delta n^{\text{ig}} RT$ when the formation reaction stoichiometry is balanced for 1 mol of the substance being formed.

Gas-phase nonidealities are calculated with the departure function at the same temperature and pressure, denoted for enthalpy as $(H - H^{\text{ig}})$ as discussed in the subsection Departure Functions from PVT Calculations resulting in $H^V = \Delta H^V_{\text{mix},T} + \sum_i x_i[(H^V - H^{\text{ig}})_T + \int_{298.15}^{T} C_P\, dT + \Delta H^f_{298.15}]$. For condensed phases the enthalpy of phase transformations are added (subsection *Phase Changes*), and any state changes of mixing (subsection *Property Changes of Mixing*) and a pressure correction. Mixing changes are large for acids, bases, and salts with water, but are generally a small contribution for organic mixture streams. When mixing changes are included, the enthalpy of a liquid stream with conventional liquid components would be

$$H^L = \Delta H^L_{\text{mix},T} + \sum_i x_i[V_i^L(P - P^{\text{sat}}_{i,T}) - \Delta H^{\text{vap}}_T + (H^V - H^{\text{ig}})_T + \int_{298.15}^{T} C_P\, dT + \Delta H^f_{298.15}] \tag{4-12}$$

For equation of state modeling of vapor phases, mixing process are usually included in the mixture departure function, resulting in $H^V = (H^V - H^{\text{ig}})_T + \sum_i x_i[\int_{298.15}^{T} C_P\, dT + \Delta H^f_{298.15}]$. For equation of state modeling of liquid phases, the mixing, pressure correction, and vaporization terms are included in the departure function, $H^L = (H^L - H^{\text{ig}})_T + \sum_i x_i[\int_{298.15}^{T} C_P\, dT + \Delta H^f_{298.15}]$.

**Phase Changes** Vaporization of a pure fluid occurs at constant temperature at the species vapor pressure $P^{\text{sat}}(T)$. The heat of vaporization is directly related to the slope of the vapor-pressure curve.

$$\Delta H^{\text{vap}} = T\,\Delta V^{\text{vap}} \frac{dP^{\text{sat}}}{dT} \tag{4-13}$$

Known as the *Clapeyron equation*, this exact thermodynamic relation provides the connection between the properties of the liquid and vapor phases at saturation. An empirical parameter frequently used in characterization of fluid properties is the *acentric factor*, defined by

$$\omega \equiv -1 - \log(P^{\text{sat}}/P_c)\big|_{T_r = 0.7} \tag{4-14}$$

where $T_r \equiv T/T_c$ is the *reduced temperature*. In application, an empirical vapor pressure versus temperature relation is commonly used such as the Antoine equation

$$\log(P^{\text{sat}}) = A - \frac{B}{T + C} \tag{4-15}$$

Experimentally, $\log P^{\text{sat}}$ is not quite linear with $1/T$ (in $\text{K}^{-1}$); however, use of Eq. (4-15) with $C = 0$ and $T$ in K is also sufficient for interpolation between reasonably spaced values of $T$. The acentric factor can be used for crude estimates of vapor pressure by neglecting the slight curvature

$$\log(P^{\text{sat}}/P_c) = (7/3)(1 + \omega)(1 - T_c/T) \tag{4-16}$$

where $T$ is in Kelvin. This approximation is sometimes referred to as *Wilson's vapor pressure equation*, but the exact attribution has been lost. More accurate equations are listed in the correlations of Sec. 2. Accurate correlations for $\Delta H^{\text{vap}}$ are available in Sec. 2, but in this section we apply a simple approximation

$$\frac{\Delta H^{\text{vap}}}{RT_c} = 7(1 - T_r)^{0.354} + 11\omega(1 - T_r)^{0.456} \qquad \text{when} \qquad P > P^{\text{sat}} \tag{4-17}$$

Equations (4-16) and (4-17) are accurate to roughly 15 percent for hydrocarbons when $T_r > 0.5$.

## THE GENERAL ENERGY BALANCE

Because energy, like mass, is conserved, the time rate of change of energy within the control volume equals the net rate of energy transfer into the control volume. Streams flowing into and out of the control volume have energy associated with them in the internal, potential, and kinetic forms, and all contribute to the energy change of the system. Energy may also flow across the control surface as heat and work. General References 1, 3 through 6, and 8 through 12 show that the general energy balance for flow processes is

$$\frac{d\left(m\left(U + \frac{v^2}{2g_c} + \frac{zg}{g_c}\right)\right)_{\text{cv}}}{dt} = \underline{\dot{Q}} + \underline{\dot{W}} + \sum_{\text{streams}}\left[\left(H + \frac{v^2}{2g_c} + \frac{zg}{g_c}\right)\dot{m}\right]_i \tag{4-18}$$

The work rate $\dot{W}$ may be of several forms. Most commonly there is shaft work $\dot{W}_s$. Work may be associated with expansion or contraction of the control volume, and there may be stirring work. Note that when a gas expands from inlet to outlet across a pressure drop, flow work is inherently included in the definition of enthalpy and not the work term. The velocity $v$ in the kinetic energy term is the bulk mean velocity as defined by the equation $v = \dot{m}/(\rho A_x)$; $z$ is elevation above a datum level, $g$ is the local acceleration of gravity, and $g_c$ is the gravitational units conversion constant.

**Energy Balances for Closed Systems** In closed systems, all mass flows across system boundaries are zero, so the last term of Eq. (4-18) is zero. The simplified energy balance then becomes

$$d\left(m\left(U + \frac{v^2}{2g_c} + \frac{zg}{g_c}\right)\right)_{\text{cv}} = \underline{\dot{Q}}\,dt + \underline{\dot{W}}\,dt \tag{4-19}$$

The most common form of energy balance is obtained by noting that changes in the velocity and altitude of most systems are usually negligible when temperature changes are present. Noting that $\underline{Q} \equiv \int \underline{\dot{Q}}\, dt$ and $\underline{W} \equiv \int \underline{\dot{W}}\, dt$, we find that

$$\Delta U = Q + W \tag{4-20}$$

***Example 4-2 Adiabatic Reversible Compression of Air*** One stroke of a positive displacement compressor is analogous to the piston-cylinder arrangement of a bicycle pump. If the stroke is fast enough, heat transfer can be neglected for the purpose of a single stroke. Suppose a pump is 35 cm long and has a 3-cm diameter with ambient air initial pressure $P_1 = 0.1$ MPa. Estimate the pressure and temperature achieved at the end of the stroke using the ideal gas law and the work done (J/mol), assuming air enters at 25°C and a weight of 80 kg is applied.

*Solution* $dU = C_V\, dT = dQ + dW = dW_{EC} = -P\, dV = -RT\, dV/V$; let $L \equiv$ length (cm) of the cylinder after compression. Rearranging gives $C_V\, dT/T = R\, dV/V$ $\Rightarrow$ $T_2/T_1 = (V_1/V_2)^{R/C_V} = (P_2/P_1)^{R/C_P}$. For the given conditions, $P_{2,\text{weight}}$ = 80 kg/(0.015$^2$ π) = 113,177 kg/m$^2$ · 9.8066 N/kg = 1.1099 MPa = 161 psig, to which we add 0.1 MPa for absolute pressure, $P_2$ = 1.21 MPa. By the ideal gas law, $P_2/P_1 = (T_2/T_1)(35/L) = (P_2/P_1)^{R/C_P}(35/L)$. Rearranging gives $L = 35(P_1/P_2)^{C_V/C_P} = 5.89$ cm; $T_2 = 608$ K = 335°C. The work done is $W_{EC} = (5/2)(8.314)(607.9 - 273.15) = 6960$ J/mol.

This example includes the ideal gas law approximation. Air near room temperature and pressure can be approximated as an ideal gas composed of nitrogen and oxygen, both of which have roughly constant $C_P$ values of 3.5$R$, and $C_V = C_P - R$ for ideal gases. Guidelines for ideal gas behavior are:

$$T/T_c \equiv T_r > 0.5 + 2(P/P_c) \quad \text{or} \quad V/V_c > 4 \quad \text{Conditions applicable to ideal gases} \tag{4-21}$$

The definition of $C_V$ leads to the substitution for the $dU$ term. The temperature rise during adiabatic compression can be quite large. We have implicitly assumed that the pressure inside the cylinder is uniformly equal to the pressure applied externally, signifying a reversible process. Hence the result for $T_2/T_1$ can be applied to any reversible, adiabatic, ideal gas process. Through the ideal gas law, this result becomes,

$$T_2/T_1 = (V_1/V_2)^{(R/C_V)} = (P_2/P_1)^{(R/C_P)} \Rightarrow PV^{\gamma} = \text{constant, ad. rev. ideal gas, } \gamma \equiv C_P/C_V \tag{4-22}$$

**Energy Balances for Steady-State Flow Processes** Flow processes for which the left-hand side of Eq. (4-18) is zero are said to occur at *steady state*. As discussed with respect to the mass balance, this means that the mass of the system within the control volume is constant; it also means that no changes occur with time in the properties of the fluid within the control volume or at its entrances and exits. The only work of the process commonly present is shaft work, and the simplified form of the general energy balance for a single inlet and single outlet, becomes

$$\Delta\left[\left(H + \frac{1}{2}\frac{v^2}{g_c} + \frac{zg}{g_c}\right)\dot{m}\right] = \underline{\dot{Q}} + \underline{\dot{W}}_s \tag{4-23}$$

Note that the sign appears to change relative to Eq. (4-18) because Δ is defined as outlet – inlet and here the absolute values of the mass flows should be used, whereas outlet mass flows inherently have negative signs in Eq. (4-18). Simplifying further, the most common energy balance for open steady-state systems neglects changes in kinetic energy and altitude.

$$\Delta H = Q + W_s \tag{4-24}$$

***Example 4-3 Continuous Adiabatic Reversible Compression of Air*** The energy balance changes when the system is viewed from a steady-state perspective. The individual strokes of the compressor, or even whether it is a positive displacement or centrifugal compressor, are irrelevant. Only the continuous flows of energy into and out of the system matter. To illustrate, consider the following example where air enters a continuous reversible compressor at 25°C and 1 bar and is adiabatically compressed to 6 bar. Compute the outlet temperature and work requirement (J/mol).

*Solution* Due to the adiabatic assumption, the heat term drops out of Eq. (4-24) and we seek $\Delta H$ to find the work. The air is treated as an ideal gas. Noting the words *adiabatic, reversible,* and *ideal gas*, we can immediately apply Eq. (4-22). The definition of $C_P$ leads to a subtle but significant distinction relative to the previous example. The energy balance simplifies as $\Delta H = \int C_P dT = Q + W = W_s$

$$W_s = C_P(T_2 - T_1) = C_P T_1\left[\left(\frac{P_2}{P_1}\right)^{R/C_P} - 1\right] \tag{4-25}$$

Substituting numerical values gives

$$T_2 = T_1(6/1)^{(1/3.5)} = 497.5\text{ K} = 224.3°\text{C} \qquad W_s = 3.5 \times 8.314(497.5 - 298.15) = 5801\text{ J/mol}$$

**Energy Balances for Chemical Manufacturing Processes** Similar to mass balances, energy balances are applicable to composite systems as well as individual subsystems. Thus it is valuable to extend PFD computations to include stream enthalpies as well as component mass flows. Highly accurate estimation of stream enthalpies is quite complicated because it involves accurate estimation of the enthalpy of compressed gases and nonideal liquids that may exhibit substantial heats of mixing. Such an approach would be very computationally intensive, hence the necessity of a process simulator. We convey the general concepts by presenting the general equations, and then we illustrate the connection between the general equations and the pathway to properties by using computationally expedient models. The general equations can be revisited at various stages to show improvements in accuracy with increasingly sophisticated computational models.

The essential relation for estimating stream enthalpies is given by

$$H(T,P,z) = \sum_i z_i\left(\Delta H_{f,i,T_R}^{o,\text{ig}}(T_R) + \int_{T_R}^{T} C_P^{\text{ig}}\, dT\right) + q(H^V(T,y) - H^{\text{ig}}) + (1-q)(H^L(T,x) - H^{\text{ig}}) \tag{4-26}$$

where $z_i$ is the overall mole fraction, and $q$ is the stream's molar vapor fraction. Here we have assumed that the reference state is defined relative to the elements at 25°C and 1 bar as in Eq. (4-12). To apply this rigorously, equations of state are used (see the subsection *Departure Functions from PVT Correlations*). For shortcut calculations, the contributions can be written,

$$(H^L(T,x) - H^{\text{ig}}) = \Delta H_{\text{mix}}^L + \sum_i x_i\left(\left(H_i^V(T, P_i^{\text{sat}}) - H_i^{\text{ig}}\right) - \Delta H_T^{\text{vap}} + V_i^L\left(P - P_{i,T}^{\text{sat}}\right)\right) \tag{4-27}$$

$$(H^V(T,y) - H^{\text{ig}}) = \left(\sum_i x_i\left(H_i^V - H_i^{\text{ig}}\right)\right) + \Delta H_{\text{mix}}^V \tag{4-28}$$

where $H^{\text{ig}}$ is calculated using Eq. (4-11). For the purpose of illustrating the pathway to computing stream enthalpies, we can make the following shortcut approximations: (1) $C_P^{\text{ig}} = C_P^{\text{ig}}(25°\text{C}) =$ constant. This is reasonably accurate for $T < 100°$C. (2) $(H^V - H^{\text{ig}}) = 0$. It neglects departures for compressed vapors and heats of mixing for vapors, but is reasonable when $P < 5$ bar. (3) $(H^L - H^{\text{ig}}) = -\sum x_i \Delta H_i^{\text{vap}}$. This neglects heats of mixing and enthalpy increases due to increased pressure.

***Example 4-4 Energy Balances for the DME Process*** The formulas above make it possible to compute an enthalpy flow (MJ/h) for each stream in Example 4-1. Heats of formation for methanol, DME, and $H_2O$ are –200.94, –184.1, and –241.835 kJ/mol. The ideal gas heat capacities at 25°C are 43.9, 65.7, and 33.6 J/mol·K. All the streams are liquid except stream 5. Tabulate these enthalpies and compute (1) the net heat flow (kW) of the heat exchanger after the reactor and (2) the net power flow (kW) for the overall process.

*Solution* Illustrating the procedure for one liquid stream and one vapor stream should suffice. Stream 5 is all vapor. From Example 4-1, the stream species flows are 306.0, 154.6, and 154.6 kmol/h. Applying Eq. (4-28),

$$\underline{\dot{H}}_5 = [306.0(-200940 + 43.9(250 - 25)) + 155.6(-184100 + 65.7(250 - 25)) + 155.6(-241835 + 33.6(250 - 25))]/1000 = -120846\text{ MJ/h}$$

Note that we retain a larger number of significant figures than would normally be warranted for such imprecise estimates. This is so because the heats of formation play a significant role in each stream enthalpy. When we take differences, the large heat of formation terms cancel for control volumes without reactions, but are necessary for control volumes that include reactions. Stream 7 is interesting as a sample stream that is liquid and relates to the heat exchanger. The ideal gas contribution can be computed as for stream 5.

$$\underline{\dot{H}}_7\,(\text{ig}) = [306.0(-200940 + 43.9\,(75 - 25)) + 155.6\,(-184100 + 65.7(75 - 25)) + 155.6(-241835 + 33.6(75 - 25))]/1000 = -125883\text{ MJ/h}$$

Applying Eq. (4-17) at 75°C for stream 7 gives 35.75, 14.19, and 42.99 kJ/mol for the heats of vaporization. Adding this to the ideal gas contribution gives

$$\underline{\dot{H}}_7 = -125883 + [306.0(-35750) + 155.6(-14190) + 155.6(-42990)]/1000 = -145661\text{ MJ/h}$$

Repeating the procedure for the other streams gives the enthalpy flows $\underline{\dot{H}} = \dot{n}H$,

| Stream | 1 | 2 | 5 | 7 | 8 | 9 | 11 | 12 |
|---|---|---|---|---|---|---|---|---|
| $\underline{\dot{H}}$(GJ/h) | –75.1 | –143.8 | –120.8 | –145.7 | –31.3 | –110.5 | –68.4 | –42.4 |

The energy balance for heat exchanger: No work is accomplished so $\Delta \underline{\dot{H}} = \underline{\dot{Q}} + \underline{\dot{W}} = \underline{\dot{Q}}$.

$$\underline{\dot{Q}} = (-145.7 + 120.8)\ (1{,}000{,}000)/(3600\ \text{s/h}) = -6900\ \text{kW}$$

The net energy balance for process involves streams 1, 8, and 12: No pumps or turbines appear in this process, so $\Delta \underline{\dot{H}} = \underline{\dot{Q}}$.

$$\underline{\dot{Q}} = (-42.4 - 31.3 + 75.1)(1{,}000{,}000)/(3600\ \text{s/h}) = 390\ \text{kW}$$

These results show that net heat addition is required even though the heat of reaction is negative. Note that the outlet streams are hotter than the inlet streams, and despite the exothermic heat of reaction, the heat exchangers, reboilers, and condensers must balance this heat duty.

## THE GENERAL ENTROPY BALANCE

The primary engineering purpose of entropy is to evaluate process thermodynamic reversibility. Entropy is defined in a closed system as

$$\Delta \underline{S} = \int_{T_1}^{T_2} \frac{\underline{Q}_{\text{rev}}}{T_{\text{cv}}}\, dT \tag{4-29}$$

where $\underline{Q}_{\text{rev}}$ is reversible heat transfer, and $T_{\text{cv}}$ is the control volume temperature at the surface where heat is transferred. Entropy changes for an ideal gas using $T$ and $P$ as independent variables can be calculated using a formula derived from Eq. (4-29) by combining an isothermal step and an isobaric step:

$$\Delta S^{\text{ig}} = \int_{T_1}^{T_2} \frac{C_P}{T}\, dT - R \ln \frac{P_2}{P_1} \quad \text{or} \quad S^{\text{ig}} = \int_{T_{\text{ref}}}^{T_2} \frac{C_P}{T}\, dT - R \ln \frac{P_2}{P_{\text{ref}}} + S_{\text{ref}} \tag{4-30}$$

Commonly $S_{\text{ref}} = 0$. If the reference state uses the elements in the naturally occurring state of aggregation, then $\Delta S^f_{T_{\text{ref}}, P_{\text{ref}}} = (\Delta H^f_{T_{\text{ref}}, P_{\text{ref}}} - \Delta G^f_{T_{\text{ref}}, P_{\text{ref}}})/T_{\text{ref}}$ is added to the last expression. The entropy balance differs from an energy balance in a very important way—entropy is not conserved and is generated by irreversibilities. Entropy generation is always $\underline{\dot{S}}_{\text{gen}} \geq 0$, where the equality applies for (hypothetical) reversible processes. The statement of balance for a control volume, expressed as rates, is therefore

$$\left\{\begin{array}{c}\text{Rate of entropy}\\ \text{change of}\\ \text{control volume}\end{array}\right\} = \left\{\begin{array}{c}\text{net rate of}\\ \text{entropy transport}\\ \text{into control volume}\end{array}\right\} + \left\{\begin{array}{c}\text{rate of entropy}\\ \text{change due to heat}\\ \text{transfer at surfaces}\end{array}\right\} + \left\{\begin{array}{c}\text{rate of}\\ \text{entropy}\\ \text{generation}\end{array}\right\}$$

The equivalent *entropy balance* is

$$\frac{d(mS)_{\text{cv}}}{dt} = -\Delta(\dot{m}S)_{\text{fs}} + \sum_{\text{surfaces}} \frac{\dot{Q}}{T_{\text{cv}}} + \underline{\dot{S}}_{\text{gen}} \tag{4-31}$$

where $\underline{\dot{S}}_{\text{gen}}$ is the entropy generation term. This equation is the general *rate* form of the entropy balance, applicable at any instant. In general application, the contribution of flowing streams is most easily incorporated by adding the sum of entropy flow $\sum(\dot{m}S)$ of the incoming streams and subtracting the sum of entropy flow of outgoing streams. The entropy calculations for streams extend the process set forth above for enthalpy. However, the entropy of mixing (see subsections *Property Changes on Mixing* and *Ideal Solution Model and Henry's Law*) cannot and should not be neglected.

For any process, the two kinds of irreversibility are (1) those *internal* to the control volume and (2) those resulting from heat transfer across finite temperature differences that may exist between the system and surroundings. When a temperature gradient exists at a boundary, the entropy balance for the boundary itself must be included when determining the entropy change of the universe. In the limiting case where for the universe (system + boundary + surroundings) $\underline{\dot{S}}_{\text{gen}} = 0$, the process is *completely reversible*, implying that

- The process is internally reversible within the control volume.
- Heat transfer between the control volume and its surroundings is reversible.

A sample application of the entropy balance is given below under the heading Turbines.

**Entropy Balances for Composite Systems** As for the energy balance, entropy balances can be useful in analyzing processes from an overall perspective. The most common applications involve idealized 100 percent reversible processes such as the Carnot engine. However, it can be meaningful to consider irreversible processes using entropy as a measure of overall thermodynamic efficiency, as in the case of availability or exergy analysis.

***Example 4-5 Carnot Efficiency*** A heat engine is to run between 340 and 260 K. As an approximation, we can assume that the engine follows the Carnot process of adiabatic reversible compression to 340 K, isothermal heat addition, adiabatic reversible expansion to 260 K, and isothermal heat removal. For the purposes of this illustration, assume the process is working on propane, where heat addition or removal could be accomplished isothermally by boiling and condensing. The entropies of the saturated vapor and saturated liquid at 340 K would define the entropy range of operation.

The equations that apply to reversible Carnot engines are as follows:

By the first law: $|\underline{W}_{\text{net}}| = |\underline{Q}_H| - |\underline{Q}_C|$

By the second law ( for a reversible process): $\dfrac{\underline{Q}_H}{T_H} + \dfrac{\underline{Q}_C}{T_C} = 0 \Rightarrow \dfrac{|\underline{Q}_H|}{|\underline{Q}_C|} = \dfrac{T_H}{T_C}$

The initial implementation of the second law recognizes that heat flows are of opposite sign for heating and cooling. The second form helps to minimize sign confusion during application.

In combination:

$$|\underline{W}_{\text{net}}| = |\underline{Q}_C| \left(\frac{T_H}{T_C} - 1\right) = |\underline{Q}_H| \left(\frac{T_H - T_C}{T_H}\right) \tag{4-32}$$

Here $|\underline{W}_{\text{net}}|$ is the net work produced by the Carnot engine after accounting for both compression and expansion; $|\underline{Q}_H|$ is the heat transferred at the hot temperature, i.e., to vaporize the propane; $T_H$ and $T_C$ are the hot and cold temperatures of the heat reservoirs between which the heat engine operates, or 340 and 260 K, respectively.

## FUNDAMENTAL RELATIONS OF CLASSICAL THERMODYNAMICS

Multivariable calculus provides a number of relations between thermodynamic variables that are quite useful for estimating stream properties. The key point is that specification of two independent variables suffices to define the state of a pure system. For example, if $T$ and ρ are known, the other properties (such as $P$, $U$, $H$, $S$) and their changes from state are implied. Through the equations of classical thermodynamics, we find that all the properties can be derived from an equation of state $P = P(\rho, T)$ by characterizing departures from ideal gas behavior.

**The Fundamental Property Relation for Pure Fluids** Energy and entropy balances can be combined to eliminate references to heat and work in favor of state variables. For a single-component, reversible, closed system, Eq. (4-31) becomes

$$d(S)_{\text{cv}} = \frac{\dot{Q}\, dt}{T_{\text{cv}}} \tag{4-33}$$

Similarly, Eqs. (4-33) and (4-19) combine to give for a simple system with uniform $T$,

$$d(U)_{\text{cv}} = \dot{Q}\, dt + \dot{W}\, dt = T\, dS + \dot{W}\, dt \tag{4-34}$$

Noting that only $W_{\text{EC}}$ is relevant for a reversible, closed system, Eqs. (4-3) and (4-34) give

$$dU = T\, dS - P\, dV \tag{4-35}$$

Equation (4-35) is the fundamental property relation. After substituting the definition of $H \equiv U + PV$, then $dH = dU + d(PV) = dU + P\, dV + V\, dP$, and

$$dH = T\, dS + V\, dP \tag{4-36}$$

The transformation from Eq. (4-35) to Eq. (4-36) suggests two additional relations, $A \equiv U - TS$ and $G \equiv U + PV - TS$, resulting in

$$dA = -S\, dT - P\, dV \tag{4-37}$$

$$dG = -S\, dT + V\, dP \tag{4-38}$$

**Relations Using Desired Independent Variables** For practical application, it is useful to select easily measured properties as desired independent variables for use in calculation of *U, H, A,* and *G*. Because the differentials of these state functions are *exact differential expressions*, application of the reciprocity relation for such expressions produces the common Maxwell relations as described in Sec. 3 in the subsection *Multivariable Calculus Applied to Thermodynamics*, and the four most frequently used Maxwell relations are developed in texts [see Elliott and Lira (2012)]. Combining Maxwell's relations with Eqs. (4-35) through (4-38) and the chain rule provides a number of useful relations.

$$dU(T,V)=\left(\frac{\partial U}{\partial T}\right)_V dT+\left(\frac{\partial U}{\partial V}\right)_T dV=C_V\,dT+\left(T\left(\frac{\partial P}{\partial T}\right)_V-P\right)dV \quad (4\text{-}39)$$

$$dH(T,P)=C_P\,dT+\left(V-T\left(\frac{\partial V}{\partial T}\right)_P\right)dP \quad (4\text{-}40)$$

$$dS(T,P)=\frac{C_P}{T}dT-\left(\frac{\partial V}{\partial T}\right)_P dP \quad (4\text{-}41)$$

$$dS(T,V)=\frac{C_V}{T}dT+\left(\frac{\partial P}{\partial T}\right)_V dV \quad (4\text{-}42)$$

As an example application of these differentials, consider the pressure correction for enthalpy due to pressure at constant temperature. If we neglect the usually small contribution of $T(\partial V/\partial T)_P$ in Eq. (4-40), then for a liquid where the fluid is approximately incompressible, the effect of pressure gives $V^L(P_2-P_1)$ as implemented in Eq. (4-27) relative to the species vapor pressure.

## BALANCE APPLICATIONS TO FLOW PROCESSES

**Duct Flow of Compressible Fluids** Thermodynamics provides equations interrelating pressure changes, velocity, duct cross-sectional area, enthalpy, entropy, and specific volume within a flowing stream. Consider the adiabatic, steady-state, one-dimensional flow of a compressible fluid in the absence of shaft work and changes in potential energy. The appropriate energy balance Eq. (4-23) with $Q$, $W_s$, and $\Delta z$ all set equal to zero is

$$\Delta H+\frac{\Delta v^2}{2g_c}=0$$

In differential form,

$$dH=-v\,dv/g_c \quad (4\text{-}43)$$

The mass balance (continuity) Eq. (4-6) here becomes $d(\rho v A_x)=d(vA_x/V)=0$, which gives

$$\frac{dV}{V}-\frac{dv}{vg_c}-\frac{dA_x}{A_x}=0 \quad (4\text{-}44)$$

Most common chemical engineering processes occur at fluid velocities substantially less than sonic. Therefore, we confine further discussion to subsonic flow. Discussion relating to near sonic or supersonic flow is available in Smith, Van Ness, and Abbott (2005). Flow rates should always be checked and recourse taken to account for supersonic effects if high flow rates are experienced.

**Nozzles** Nozzle flow is quite specialized in that a properly designed nozzle varies its cross-sectional area with length in such a way as to make the flow nearly frictionless. The limit is adiabatic, reversible flow, for which the rate of entropy increase is zero. An analytical expression relating velocity to pressure in an isentropic nozzle is readily derived for an ideal gas with constant heat capacities. Combination of Eqs. (4-36) and (4-43) for isentropic flow gives

$$v\,dv/g_c=-V\,dP$$

Integration, with nozzle entrance and exit conditions denoted by 1 and 2, yields for an ideal gas with constant $\gamma\equiv C_P/C_V$

$$\frac{v_2^2-v_1^2}{g_c}=-2\int_{P_1}^{P_2}V\,dP=\frac{2\gamma P_1V_1}{\gamma-1}\left[1-\left(\frac{P_2}{P_1}\right)^{(\gamma-1)/\gamma}\right] \quad (4\text{-}45)$$

where the final term is obtained upon elimination of $V$ by $PV^\gamma$ = constant, following Eq. (4-22).

**Throttling Processes** Fluid flowing through a restriction, such as an orifice, without appreciable change in kinetic or potential energy undergoes a finite pressure drop. This *throttling process* produces no shaft work, and in the absence of heat transfer, Eq. (4-24) reduces to $\Delta H=0$ or $H_2=H_1$. The process therefore occurs at constant enthalpy.

The temperature of an ideal gas is not changed by a throttling process because $dH^{ig}=C_P\,dT$. For most real gases at moderate conditions of $T$ and $P$, a reduction in pressure at constant enthalpy results in a decrease in temperature, although the effect is usually small.

Throttling of a wet vapor causes the liquid to evaporate, resulting in a considerable temperature drop because of the evaporation of liquid, and depending on the pressure drop, the evaporation may be complete.

If a saturated liquid is throttled to a lower pressure, some of the liquid vaporizes or *flashes*, producing a mixture of saturated liquid and vapor at the lower pressure. For a pure fluid, the outlet temperature is the saturation temperature at the outlet pressure, which may be very cold.

**Turbines (Expanders)** High-velocity streams from nozzles impinging on blades attached to a rotating shaft from a turbine (or expander) through which vapor or gas flows in a steady-state expansion process that converts the internal energy of a high-pressure stream into shaft work. The motive force is usually provided by a (steam) turbine or a high-pressure (gas) expander.

In any properly designed adiabatic turbine, heat transfer and changes in potential and kinetic energy are negligible. Equation (4-24) therefore reduces to

$$W_s=\Delta H=H_2-H_1 \quad (4\text{-}46)$$

The rate form of this equation is

$$\dot{W}_s=\dot{m}\Delta H=\dot{m}(H_2-H_1) \quad (4\text{-}47)$$

When inlet conditions $T_1$ and $P_1$ and discharge pressure $P_2$ are known, the value of $H_1$ is fixed. In Eq. (4-46) both $H_2$ and $W_s$ are unknown, and the energy balance alone does not allow their calculation. However, if the fluid expands *reversibly and adiabatically* in the turbine, then the process is isentropic ($S_2=S_1$). This entropy balance establishes the final state of the fluid and allows calculation of $H_2$. Equation (4-47) then gives the isentropic (reversible) work, and the prime denotes the reversible process:

$$W_s'=\Delta H' \quad (4\text{-}48)$$

The absolute value $|W_s'|$ is the *maximum* work that can be produced by an adiabatic turbine with given inlet conditions and given discharge pressure. Because the actual expansion process is irreversible, *expander efficiency* is defined as

$$\eta_E\equiv\frac{W_s}{W_s'}$$

where $W_s$ is the actual shaft work. By Eqs. (4-47) and (4-48),

$$\eta_E=\frac{\Delta H}{\Delta H'} \quad (4\text{-}49)$$

Values of $\eta_E$ usually range from 0.7 to 0.8.

***Example 4-6 Turbine Process Design*** Steam is expanded in a turbine from 500°C and 1.4 MPa to an outlet of 0.6 MPa. If the turbine is 75 percent efficient, how much work can be obtained per kilogram of steam (kJ/kg)? Use the steam tables from Elliott and Lira (2012).

*Solution* The inlet conditions are $H_1$ = 3474.8 kJ/kg and $S_1$ = 7.6047 kJ/kg·K. To apply Eq. (4-49) the reversible calculation is performed first. Interpolating at the outlet state pressure using $S_2'$ = 7.6047 kJ/kg·K gives $H_2'$ = 3202.8 kJ/kg. Then $\Delta H=W_S=\Delta H'$ $\eta_E=(3202.8-3474.8)(0.75)=-204$ kJ/kg.

**Compressors** Compressors, pumps, fans, blowers, and vacuum pumps are all devices designed to produce pressure increases. The energy Eqs. (4-43) through (4-48) are the same for adiabatic compression, based on the same assumptions, as for turbines or expanders. A specialized equation of state (EOS) would be applied for steam or polar fluids, whereas a generalized EOS typically would be applied for the fluids involved in compressors.

The isentropic work of compression, as given by Eq. (4-48), is the *minimum* shaft work required for compression of a gas from a given initial state to a given discharge pressure. *Compressor efficiency* is defined as (again using the prime to denote the reversible process)

$$\eta_C \equiv \frac{W_s'}{W_s}$$

The relation between the reversible and actual process is inverted relative to a turbine. In view of Eqs. (4-46) and (4-48), this becomes

$$\eta_C \equiv \frac{\Delta H'}{\Delta H} \tag{4-50}$$

Compressor efficiencies are usually in the range of 0.7 to 0.8.

**Pumps** Liquids are moved by pumps, and the same equations apply to adiabatic pumps as to adiabatic compressors. Thus, Eqs. (4-46) to (4-48) and (4-50) are valid. However, application of Eq. (4-46) requires values of the enthalpy of compressed (subcooled) liquids, and these are seldom available. The enthalpy relation, Eq. (4-36), provides an alternative. For an isentropic process,

$$dH = V\,dP \text{ (constant } S\text{)}$$

Combining this with Eq. (4-48) yields

$$W_s' = \Delta H' = \int_{P_1}^{P_2} V\,dP$$

The usual assumption for liquids (at conditions well removed from the critical point) is that $V$ is independent of $P$. Integration then gives

$$W_s' = \Delta H' = V(P_2 - P_1) = \Delta P/\rho \tag{4-51}$$

# PROPERTY CALCULATIONS FROM EQUATIONS OF STATE

The most satisfactory calculation procedure for the thermodynamic properties of gases and vapors is based on ideal gas state heat capacities and quantification of the nonidealities using departure functions. Of primary interest are the enthalpy and entropy departures, defined as the difference between the state properties of the real fluid and an ideal gas at the same *pressure* and *temperature*:

$$(H - H^{ig}) \equiv H^{dep} \quad \text{and} \quad (S - S^{ig}) \equiv S^{dep} \tag{4-52}$$

These departures are integrated into the process calculations, e.g., see Eq. (4-12). The reader is cautioned that departure functions are sometimes called *residual properties*, and sign conventions for the definitions differ in literature.

## DEPARTURE FUNCTIONS FROM *PVT* CORRELATIONS

The departure functions of gases and vapors depend on their *PVT* behavior. This is often expressed through correlations for the compressibility factor $Z$, defined by

$$Z \equiv PV/(RT) \tag{4-53}$$

Analytical expressions for $Z$ as functions of $T$ and $P$ or $T$ and $V$ are known as *equations of state* (EOSs). Since most EOSs are in terms of $T$ and $V$, the most useful relations are Eqs. (4-37) and (4-39). Elliott and Lira (2012) show how these can be rearranged in the most convenient form:

$$\left(\frac{\partial U}{\partial V}\right)_T = T\left(\frac{\partial P}{\partial T}\right)_V - P \Rightarrow \frac{U^{dep}}{RT} = \int_0^{\rho} -T\left(\frac{\partial Z}{\partial T}\right)_\rho \frac{d\rho}{\rho} \tag{4-54}$$

$$\left(\frac{\partial A}{\partial V}\right)_T V = -PV \Rightarrow \frac{A^{dep}_{T,V}}{RT} = \int_0^{\rho} \frac{Z-1}{\rho}\,d\rho \tag{4-55}$$

The subscript $T, V$ in Eq. (4-55) indicates that this departure is evaluated at the same $T, V$ for the real fluid and ideal gas: $A^{dep}_{T,V} = A(T, V) - A^{ig}(T,V)$. Most applications require residuals at given $T, P$. The properties of the real fluid imply unique values of $T, P$, and $V$, but the pressure obtained from the ideal gas equation given $T, V$ is not equal to the real fluid's $P$. A translation in the ideal gas state of $\ln Z$ is used to obtain $A^{dep} = A(T, P) - A^{ig}(T, P)$.

$$\frac{A^{dep}}{RT} = \frac{A^{dep}_{T,V}}{RT} - \ln Z = \int_0^{\rho} \frac{Z-1}{\rho}\,d\rho - \ln Z \tag{4-56}$$

Other departure functions can be derived from the definitions of $U, H, A, G$, and $S$.

$$\frac{S^{dep}}{R} = \frac{U^{dep} - A^{dep}}{RT} - \ln Z = -\int_0^{\rho} \left[T\left(\frac{\partial Z}{\partial T}\right)_\rho + (Z-1)\right]\frac{d\rho}{\rho} - \ln Z \tag{4-57}$$

$$\frac{H^{dep}}{RT} = \frac{U^{dep} + PV - (PV)^{ig}}{RT} = -\int_0^{\rho} T\left(\frac{\partial Z}{\partial T}\right)_\rho \frac{d\rho}{\rho} + Z - 1 \tag{4-58}$$

$$\frac{G^{dep}}{RT} = \frac{A^{dep}}{RT} + Z - 1 = \int_0^{\rho} \frac{Z-1}{\rho}\,d\rho + Z - 1 - \ln Z \tag{4-59}$$

A few EOSs may be reformulated to give $P$ as a function of $T$ and $V$ or $V$ as a function of $T$ and $P$, in which case Eqs. (4-38) and (4-40) are more convenient.

$$\left(\frac{\partial H}{\partial P}\right)_T = V - T\left(\frac{\partial V}{\partial T}\right)_P \Rightarrow \frac{H^{dep}}{RT} = -\int_0^{P} T\left(\frac{\partial Z}{\partial T}\right)_P \frac{dP}{P} \tag{4-60}$$

$$P\left(\frac{\partial G}{\partial P}\right)_T = PV \Rightarrow \frac{G^{dep}}{RT} = \int_0^{P} \frac{Z-1}{P}\,dP \tag{4-61}$$

$$\frac{S^{dep}}{R} = -\int_0^{P} \left[T\left(\frac{\partial Z}{\partial T}\right)_P + Z - 1\right]\frac{dP}{P} \tag{4-62}$$

## CHEMICAL POTENTIAL, FUGACITY, AND FUGACITY COEFFICIENT

The chemical potential $\mu$ plays a vital role in both phase and chemical reaction equilibria. However, the chemical potential exhibits certain unfortunate characteristics that discourage its use in the solution of practical problems. For pure fluids, $\mu = G \equiv H - TS$ defines $\mu$ in terms of the internal energy and entropy, both primitive quantities for which absolute values are unknown. Moreover, $\mu$ approaches negative infinity when $P$ approaches zero. While these characteristics do not preclude the use of chemical potentials, the application of equilibrium criteria is facilitated by introduction of the *fugacity*, a quantity that takes the place of $\mu$ and overcomes its less desirable characteristics. The Gibbs energy departure of a real fluid is related to the fugacity by

$$G^{dep} = G - G^{ig} = RT \ln \frac{f}{P} \tag{4-63}$$

The dimensionless ratio $f/P$ is another new property called the *fugacity coefficient* $\phi$. Thus,

$$G^{dep} = RT \ln \phi \tag{4-64}$$

where

$$\phi \equiv \frac{f}{P} \quad \text{or} \quad f = \phi P \tag{4-65}$$

The definition of fugacity is completed by setting the ideal gas state fugacity of pure species $i$ equal to its pressure, $f_i^{ig} = P$. Thus for the special case of an ideal gas, $G_i^{dep} = 0$, $\phi_i = 1$. From the phase equilibrium criterion, $\mu^\alpha = \mu^\beta$ when phases $\alpha$ and $\beta$ are in equilibrium. Substitution into Eq. (4-63) shows that $f^\alpha = f^\beta$ is equivalent.

$$\mu^\alpha = \mu^\beta \qquad f^\alpha = f^\beta \tag{4-66}$$

For condensed phases, Eq. (4-65) is used to calculate the saturation fugacity (at the vapor pressure or sublimation pressure), and then Eq. (4-38) is used to add a pressure correction,

$$f^{cond} = \phi^{sat} P^{sat} \exp[V^{cond}(P - P^{sat})/(RT)] \tag{4-67}$$

where the exponential term is known as the *Poynting correction*, and $V^{\text{cond}}$ is the molar volume of the condensed phase. As written, the Poynting correction assumes the condensed phase is incompressible.

## APPLICATIONS OF DEPARTURE FUNCTIONS

**Virial Equations of State** The virial equation in *density* is an infinite series expansion of the compressibility factor $Z$ in powers of molar density $\rho$ (or reciprocal molar volume $V^{-1}$) about the real gas state at zero density (zero pressure):

$$Z = 1 + B\rho + C\rho^2 + D\rho^3 + \cdots \tag{4-68}$$

The density series virial coefficients $B$, $C$, $D$, … depend on temperature and composition only. In practice, truncation is to two terms. For engineering purposes, $P$ is more convenient than density, and the pressure through mathematical reversion of the series is

$$Z = 1 + BP/(RT) + \cdots \tag{4-69}$$

For a pure fluid, Eq. (4-61) gives

$$\phi = \exp(BP/(RT)) \tag{4-70}$$

The composition dependency of $B$ is given by the exact *mixing rule*

$$B = \sum_i \sum_j y_i y_j B_{ij} \tag{4-71}$$

where $y_i$ and $y_j$ are mole fractions for a gas mixture and $i$ and $j$ identify species. The coefficient $B_{ij}$ characterizes a bimolecular interaction between molecules $i$ and $j$, and therefore $B_{ij} = B_{ji}$. Two kinds of second virial coefficient arise: $B_{ii}$ and $B_{jj}$ (the subscripts are the same), and $B_{ij}$ (they are different). The first is a virial coefficient for a pure species; the second is a mixture property, called a *cross-coefficient*.

An extensive set of three-parameter corresponding-states correlations has been developed by Pitzer and coworkers [Pitzer, *Thermodynamics*, 3d ed., App. 3, McGraw-Hill, New York, 1995]:

$$\frac{BP_c}{RT_c} = B^0 + \omega B^1 \tag{4-72}$$

with the *acentric factor* defined by Eq. (4-14). For pure chemical species $B^0$ and $B^1$ are functions of reduced temperature only. Substitution for $B$ in Eq. (4-69) by this expression gives

$$Z = 1 + (B^0 + \omega B^1)\frac{P_r}{T_r} \tag{4-73}$$

where $T_r = T/T_c$ and $P_r = P/P_c$ are the *reduced temperature* and *reduced pressure*. Detailed discussion of $B^0$ and $B^1$ and their derivatives is given in Elliott and Lira (2012, p. 259):

$$B^0 = 0.083 - \frac{0.422}{T_r^{1.6}} \tag{4-74}$$

$$B^1 = 0.139 - \frac{0.172}{T_r^{4.2}} \tag{4-75}$$

Substituting into Eqs. (4-60) and (4-62) and integrating give

$$\frac{H^{\text{dep}}}{RT} = -P_r\left(\frac{1.0972}{T_r^{2.6}} - \frac{0.083}{T_r} + \omega\left(\frac{0.8944}{T_r^{5.2}} - \frac{0.139}{T_r}\right)\right) \tag{4-76}$$

$$\frac{S^{\text{dep}}}{R} = -P_r\left(\frac{0.675}{T_r^{2.6}} + \omega\frac{0.722}{T_r^{5.2}}\right) \tag{4-77}$$

$$\frac{G^{\text{dep}}}{RT} = \frac{H^{\text{dep}}}{RT} - \frac{S^{\text{dep}}}{R} \tag{4-78}$$

Although limited to pressures where the two-term virial equation in pressure has approximate validity, these correlations are applicable for many chemical processing conditions. The second virial equation is reliable at higher pressures when the temperature is also higher in accordance with the following guideline:

$$T_r > 0.686 + 0.439P_r \qquad \text{or} \qquad V_r > 2.0 \tag{4-79}$$

Values for the cross coefficients $B_{ij}$, with $i \neq j$, and their derivatives are provided by Eq. (4-72) written in extended form:

$$B_{ij} = \frac{RT_{cij}}{P_{cij}}(B^0 + \omega_{ij}B^1) \tag{4-80}$$

where $B^0$ and $B^1$ are the same functions of $T_r$ as given by Eqs. (4-74) and (4-75), and $T_{rij} = T/T_{cij}$. The combining rules for $\omega_{ij}$, $T_{cij}$, and $P_{cij}$ are given by Elliott and Lira (2012, p. 580).

A primary merit of Eqs. (4-74) and (4-75) for second virial coefficients is simplicity. Generalized correlations for $B$ are given by Meng, Duan, and Li [*Fluid Phase Equilibr.* **226**:109–120 (2004)]. More complex correlations of somewhat wider applicability include those by Tsonopoulos [*AIChE J.* **20:** 263–272 (1974); **21:** 827–829 (1975); **24:** 1112–1115 (1978); *Adv. in Chemistry Series* 182, pp. 143–162 (1979)]. For polar and associating molecules, the correlation of Hayden and O'Connell [*Ind. Eng. Chem. Proc. Des. Dev.* **14:** 209–216 (1975)] is generally preferred. For aqueous systems, see Bishop and O'Connell [*Ind. Eng. Chem. Res.* **44:** 630–633 (2005)].

**Extended Virial and Multiparameter Equations** Another class of equations, known as an *extended* virial equation, was introduced by Benedict, Webb, and Rubin [*J. Chem. Phys.* **8:** 334–345 (1940); **10:** 747–758 (1942)]. This equation contains eight parameters, all functions of composition. It and its modifications, despite their complexity, find application in the petroleum and natural gas industries for light hydrocarbons and a few other commonly encountered gases [Lee and Kesler, *AIChE J.* **21:** 510–527 (1975)].

Similar in spirit to the Benedict, Webb, and Rubin (BWR) model, highly accurate equations can be developed when extensive experimental data are available. These equations are generally written as density expansions of the Helmholtz energy that may involve up to 54 parameters. For example, the IAPWS equation [Wagner, W., and A. Pruss, *J. Phys. Chem. Ref. Data* **31:** 387–535 (2002)] for the properties of steam applies this approach. Solution for the compressibility factor and internal energy can be obtained by differentiating the Helmholtz energy according to

$$Z - 1 = \frac{\rho}{RT}\left(\frac{\partial(A - A^{\text{ig}})_{T,V}}{\partial\rho}\right)_T \tag{4-81}$$

$$\frac{U - U^{\text{ig}}}{RT} = \frac{1}{RT}\left(\frac{\partial((A - A^{\text{ig}})_{T,V}/T)}{\partial(1/T)}\right)_\rho \tag{4-82}$$

The NIST Chemistry Webbook [E. W. Lemmon, M. O. McLinden, and D. G. Friend, "Thermophysical Properties of Fluid Systems," in NIST Standard Reference Database 69, eds. W. G. Mallard and P. J. Linstrom, http://webbook.nist.gov, Gaithersburg, MD, 2016 (retrieved Nov. 8, 2016)] implements the IAPWS equation and similar equations for roughly 100 compounds common in natural gas and refrigeration industries. The relatively small list of compounds for which multiparameter equations exist has been somewhat limiting for these types of models. Recent progress has expanded this list considerably, however, with the promise of greater expansions in the near future. Another traditional limitation has been the extension to mixtures, but similar recent progress has established the GERG-2008 model as a viable method for high-accuracy treatment of streams related to the natural gas industry [O. Kunz and W. Wagner, *J. Chem. Eng. Data* **57:** 3032 (2012)]. It is likely that highly accurate equations will become available for 200 to 300 pure compounds and nonpolar mixtures within the next 5 to 10 years.

**Cubic Equations of State** The modern development of cubic equations of state started in 1949 with publication of the Redlich-Kwong (RK) equation [*Chem. Rev.* **44:** 233–244 (1949)], and many others have since been proposed. An extensive review is given by Valderrama [*Ind. Eng. Chem. Res.* **42:** 1603–1618 (2003)]. Of the equations published more recently, the two most popular are the Soave-modified RK (SRK) equation [*Chem. Eng. Sci.* **27:** 1197–1203 (1972)] and the Peng-Robinson (PR) equation [*Ind. Eng. Chem. Fundam.* **15:** 59–64 (1976)]. Since these two are functionally equivalent, the present discussion focuses arbitrarily on the PR model

$$P = \frac{RT}{V - b} - \frac{a(T)}{(V^2 + 2Vb - b^2)}, \quad Z = \frac{1}{1 - b\rho} - \frac{a}{bRT}\frac{b\rho}{[1 + 2b\rho - (b\rho)^2]} \tag{4-83}$$

where parameters $a(T)$ and $b$ are substance-dependent.

$$a(T) = 0.45723553\frac{\alpha(T_r)R^2T_c^2}{P_c} \tag{4-84}$$

$$b = 0.0777960\frac{RT_c}{P_c} \tag{4-85}$$

Function $\alpha(T_r)$ is an empirical expression specific to a particular form of the equation of state.

$$\alpha \equiv \left[1+\kappa\left(1-\sqrt{T_r}\right)\right]^2 \qquad \kappa \equiv 0.37464+1.54226\omega-0.26992\omega^2$$

As an equation cubic in $V$ or $\rho$, Eq. (4-83) has three roots, of which two may be complex numbers. Physically meaningful values of $V$ are always real numbers, positive and greater than parameter $b$. The quantity $b\rho$ is effectively the packing fraction and must range between 0 and 1.0. When $T > T_c$, solution at any positive value of $P$ yields only one real positive root. When $T = T_c$, this is also true, except at the critical pressure, where three roots exist, all equal. For $T < T_c$, only one real positive (liquid-like) root exists at high pressures, but for a range of lower pressures there are three. Here, the middle root is of no significance; the smallest root is a liquid or liquid-like volume, and the largest root is a vapor or vapor-like volume. In principle, cubic equations have the advantage that they can be solved analytically. This may be convenient for some calculations, but most process simulators apply iterative solution. Reasons are that the analytical solution may have round-off errors for the liquid root at low temperatures [R. Monroy-Loperena, *Ind. Eng. Chem. Res.* **51:** 6972 (2012)], and also because iterative Newton-like methods enable avoiding trivial solutions through the use of the pseudo-root technique, as described on page 4-25.

Cubic equations of state may be applied to mixtures through expressions that give the parameters as functions of composition. No established theory strictly prescribes the form of this dependence, and empirical *mixing rules* are often used to relate mixture parameters to pure-species parameters. The simplest realistic expressions (known as van der Waal's mixing rules) are a linear mixing rule for parameter $b$ and a quadratic mixing rule for parameter $a$

$$b = \sum_i x_i b_i \tag{4-86}$$

$$a = \sum_i \sum_j x_i x_j a_{ij} \tag{4-87}$$

with $a_{ij} = a_{ji}$. The $a_{ij}$ are of two types: pure-species parameters (identical subscripts) and interaction parameters (unlike subscripts). Parameter $b_i$ is for pure species $i$. The interaction parameter $a_{ij}$ is often evaluated from pure-species parameters by a geometric mean *combining rule* known as the *Lorentz-Berthelot rule*

$$a_{ij} = (a_i a_j)^{1/2}(1 - k_{ij}) \tag{4-88}$$

where $k_{ij}$ is an empirical binary parameter that should be fit to experimental data. These traditional equations yield mixture parameters solely from parameters for the pure constituent species. They are most likely to be satisfactory for mixtures composed of simple and chemically similar molecules. Because cubic equations provide reasonable results for nonpolar mixtures, and they have been available since the mid-1970s, they have become the workhorses for chemical process modeling. In cases where their deficiencies are unacceptable, customized empirical adaptations are generally developed. This leads to some fracturing of modeling efforts as specialists in different companies make the adaptations and they become private. Over the long term, however, there is a tendency for the more accurate adaptations to find their way into process simulators. In particular, the modified Huron-Vidal [cf. M. Michelsen, *Fluid Phase Equilibr.* **60:** 213 (1990)] and Wong-Sandler [*AIChE J.* **38:** 671 (1992)] mixing rules are similar in flexibility to the activity models discussed below, while maintaining the applicability of equations of state to dense, near-critical fluids.

One desirable feature of the cubic EOSs is the simplicity of their working equations for departure functions. As an example, the departure functions for the Peng-Robinson EOS are

$$\frac{H^{\text{dep}}}{RT} = Z - 1 - \frac{A}{B\sqrt{8}}\left(1+\frac{\kappa\sqrt{T_r}}{\sqrt{\alpha}}\right)\ln\left[\frac{Z+(1+\sqrt{2})B}{Z+(1-\sqrt{2})B}\right] \tag{4-89}$$

$$\frac{S^{\text{dep}}}{R} = \ln(Z-B) - \frac{A}{B\sqrt{8}}\frac{\kappa\sqrt{T_r}}{\sqrt{\alpha}}\ln\left[\frac{Z+(1+\sqrt{2})B}{Z+(1-\sqrt{2})B}\right] \tag{4-90}$$

$$\frac{G^{\text{dep}}}{RT} \equiv \ln\phi = Z - 1 - \ln(Z-B) - \frac{A}{B\sqrt{8}}\ln\left[\frac{Z+(1+\sqrt{2})B}{Z+(1-\sqrt{2})B}\right] \tag{4-91}$$

where the parameters are made dimensionless

$$A \equiv aP/(RT)^2 \qquad B \equiv bP/(RT) \tag{4-92}$$

and for a mixture, the parameters of Eqs. (4-86) to (4-88) are similarly made dimensionless. Do not confuse $A$ with Helmholtz energy, nor confuse $B$ with the virial coefficient.

***Example 4-7 Estimating Enthalpy Using the PR EOS*** Compute the enthalpies (kJ/kg) of saturated vapor and liquid methane and the enthalpy of vaporization, using the PR EOS at 115 K, and compare to the values given in the NIST Webbook. Also compare the heat of vaporization computed by the shortcut equation. Use the ideal gas elements at 25°C and 1 bar as the reference state for the PR EOS.

*Solution* The density is most easily solved by rearranging the PR EOS in terms of $Z$:

$$Z = \frac{1}{1-b\rho} - \frac{a}{bRT}\frac{b\rho}{[1+2b\rho-(b\rho)^2]} = \frac{1}{1-B/Z} - \frac{A}{B}\frac{B/Z}{[1+2B/Z-(B/Z)^2]} \tag{4-93}$$

Cross-multiplying and collecting terms give

$$Z^3 - Z^2(1-B) + Z(A-3B^2-2B) - (AB-B^2-B^3) = 0 \tag{4-94}$$

In principle, solving for vapor pressure using an EOS involves trial and error. We can take Eq. (4-16) as an initial guess, giving $P^{\text{sat}} \approx 0.130$ MPa. This leads to $A = 0.04178$ and $B = 0.003627$. Solving the cubic equation with an initial guess of $Z = 1$ gives $Z^V = 0.9606$ and $f^V = 0.1246$ MPa. Solving with an initial guess of $Z = 0$ gives $Z^L = 0.004627$ and $f^L = 0.1280$ MPa. Iterating on $P^{\text{sat}}$ to obtain $f^V = f^L$ gives $P^{\text{sat}} = 0.1332$, with $\rho^V = 0.002329$ g/cm$^3$, $(H^{\text{dep}})^V = -93.63$ J/mol; $f^V = 0.1280$ MPa; $\rho^L = 0.4695$ g/cm$^3$, $(H^{\text{dep}})^L = -8200.51$ J/mol; $f^L = 0.1280$ MPa. A polynomial form for methane is $C_p^{ig} = 19.25 + 0.05213T + 1.197(10^{-5})T^2 - 1.132(10^{-8})T^3$. Noting that $\Delta H_f^\circ = -74{,}893.6$ J/mol and applying Eq. (4-26), we have $H^V = -5022.61$ and $H^L = -5528.05$ kJ/kg. Taking the difference gives $\Delta H^{\text{vap}} = 505.4$ kJ/kg. This compares to 506.4 from Eq. (4-17). The NIST Webbook gives $P = 0.1322$ MPa, $H^L = 11.687$, and $H^V = 516.28$, leading to $\Delta H^{\text{vap}} = 504.6$ kJ/kg. Using the Webbook as a basis for comparison, the PR EOS gives a 0.76 percent deviation in $P^{\text{sat}}$ and 0.17 percent in $H^{\text{vap}}$. Equations (4-16) and (4-17) give 2.0 percent and 0.34 percent deviations. Example 4-7 gives a 0.040 percent deviation in $\Delta H^{\text{vap}}$. Several notes can be made about these results:

1. These deviations pertain to comparisons at only a single point. Similar comparisons at 100 K give 1.2 percent and 0.087 percent deviations in $P^{\text{sat}}$ and $\Delta H^{\text{vap}}$ for the PR EOS relative to 2.4 percent and 1.8 percent for Eqs. (4-16) and (4-17), respectively. More comparisons at 175 K give 0.81 percent and 3.6 percent deviations in $P^{\text{sat}}$ and $\Delta H^{\text{vap}}$ for the PR EOS relative to 2.2 percent and 0.53 percent for Eqs. (4-16) and (4-17).
2. For whatever model an engineer may be using, the model estimates should be validated against the experiment. When a multiparameter EOS is available, the NIST results can be relied upon as accurate characterizations of experimental data. In general, NIST's ThermoLit resource [http://trc.nist.gov/thermolit/main/home.html#home] provides a reliable summary of the available experimental literature. The above example illustrates the procedure for validating models for $P^{\text{sat}}$ and $\Delta H^{\text{vap}}$. It is simply a summary of deviations over the conditions' range of interest.
3. The PR EOS generally provides superior accuracy relative to Eqs. (4-16) and (4-17). This might be more apparent if our comparison were based on a component other than methane, which played a substantial role in the development of Eqs. (4-16) and (4-17).
4. Equations (4-16) and (4-17) provide reasonable estimates, especially for methane. Equation (4-16) is exact at $T_r = 0.7$ and 1.0 because it is a linear interpolation between these two points, so comparisons at these conditions (133 K and 191 K for methane) would make the model look uncharacteristically accurate.
5. When using Eq. (4-17) with (4-27), the accuracy of $H^L$ depends on inclusion of the $(H^{\text{dep}})^V$ even when Eq. (4-17) is accurate. While it might be possible to provide a shortcut estimate of $(H^{\text{dep}})^V$, the PR EOS is reliable and readily available in process simulators. Shortcut estimates should only be used as checks that can be performed with hand calculations.
6. The values of enthalpy from the various sources cannot be compared directly. For example, the values of $H^V$ at 115 K are –5022.61 kJ/kg by the PR EOS, and 516.28 on the Webbook. These large discrepancies are due to different reference states. If interest is limited to a single component, then the reference state can be chosen arbitrarily, but that would be a poor practice in the general case of multicomponent process simulations.
7. Solving for vapor pressure of an EOS requires iteration until the fugacities of vapor and liquid are equal.
8. Incorporation of the PR EOS into manual calculations is facilitated by software available at websites such as CheThermo.net. The PREOS.xls workbook was used for the computations illustrated here.

**Pitzer (Lee-Kesler) Correlations** In addition to the corresponding-states correlation for the second virial coefficient, Pitzer and coworkers [*Thermodynamics*, 3d ed., App. 3, McGraw-Hill, New York, 1995] developed a full set of generalized correlations. They have as their basis an equation for the compressibility factor, given by

$$Z = Z^0 + \omega Z^1 \tag{4-95}$$

where $Z^0$ and $Z^1$ are each functions of reduced temperature $T_r$ and reduced pressure $P_r$. The acentric factor $\omega$ is defined by Eq. (4-14).

Pitzer's original correlations for $Z$ and the derived quantities were determined graphically and presented in tabular form. Since then, analytical refinements to the tables have been developed, with extended range and accuracy. The most popular Pitzer-type correlation is that of Lee and Kesler [*AIChE J.* **21:** 510–527 (1975)]; the advent of computers has made the original tabular and graphical implementations obsolete.

Although the Pitzer correlations are based on data for pure materials, they may also be used for the calculation of mixture properties. A set of recipes is

required relating the parameters $T_c$, $P_c$, and ω for a mixture to the pure-species values and to composition. One such set is given by Eqs. (2-80) through (2-82) in the Seventh Edition of *Perry's Chemical Engineers' Handbook* (1997). These equations define *pseudoparameters*, so called because the defined values of $T_{pc}$, $P_{pc}$, and $\omega_{pc}$ have no physical significance for the mixture. The Lee-Kesler correlations provide reliable data for nonpolar and slightly polar fluids; errors of less than 3 percent are likely. Larger errors can be expected in applications to highly polar and associating fluids.

**Wertheim's Theory and SAFT Equations of State** The reader may have noticed caveats pertaining to polar molecules for all the models mentioned so far. To clarify, the term *polar* is generally applied to molecules that may be either mildly polar, such as $CO_2$, or associating, such as $H_2O$. A particularly common form of association is hydrogen bonding, which occurs in $H_2O$, alcohols, aldehydes, some amides, and some amines. The primary distinction between association and mild polarity is that association leads to specific orientations between molecules where interactions are quite strong, while polarity leads to a broader distribution of orientations that are generally favored. For example, inaccuracies in the PR EOS may be small for mildly polar pure fluids, but larger for associating fluids. The inaccuracies might be much larger when mixing mildly polar fluids with associating fluids because polarity without association is generally correlated with strong asymmetry in either acid or base character. The statistical associating fluid theory (SAFT) family of equations was developed to address limitations related to molecular polarity [W. G. Chapman, K. E. Gubbins, G. Jackson, and M. Radosz, *Fluid Phase Equilibr.* **52:** 31 (1989)]. Many implementations of this theory have been developed since the 1990s. A recent review [S. P. Tan, H. Adidharma, and M. Radosz, *Ind. Eng. Chem. Res.* **47:** 8063 (2008)] concluded that PC-SAFT [J. Gross and G. Sadowski, *Ind. Eng. Chem. Res.* **40:** 1244 (2001)] provided a reasonable representation of what can generally be achieved. The SAFT EOSs are best expressed in terms of the Helmholtz energy:

$$\frac{(A-A^{\text{ig}})_{T,V}}{RT}=\frac{(A_0-A^{\text{ig}})_{T,V}}{RT}+\frac{A_1}{T}+\frac{A_2}{T^2}+A^{\text{assoc}} \tag{4-96}$$

The equations for $A_0$, $A_1$, $A_2$, and $A^{\text{assoc}}$ are semiempirical in the sense that their qualitative behavior has been validated with comparison to molecular simulation data.

The association term was specifically developed based on Wertheim's theory, a rigorous theory for associating molecules [M. S. Wertheim, *J. Stat. Phys.* **35:** 19 (1984)]. Wertheim's theory is equivalent to modeling association as weak chemical reactions under certain conditions [J. R. Elliott, S. J. Suresh, M. D. Donohue, *Ind. Eng. Chem. Res.* **29:** 1476, (1990), A. M. Bala, C. T. Lira, *Fluid Phase Equilibr,* **430**: 47 (2016)], but Wertheim's use of site balances rather than species balances facilitates more general application. Molecules that are polar but not strictly associating can also be approximated with this theory. The significance of having a close relationship between the equation of state and the rigors of molecular simulation is that the firm theoretical basis provides insights into the proper mixing rules. Another advantage of Wertheim's theory is realized when taking the limit of the association energy to infinity. A reasonable model of a covalently bonded chain is obtained, mimicking polymeric species, again with validated behavior relative to molecular simulation.

Wertheim's theory has also been implemented to achieve a smooth transition between cubic equations and an association model. The Cubic Plus Association (CPA) model applies the SRK model for nonassociating species and an adaptation of Wertheim's theory for associating species [G. M. Kontogeorgis, M. L. Michelsen, G. K. Folas, S. Derawi, N. von Solms, and E. H. Stenby, *Ind. Eng. Chem. Res.* **45:** 4869 (2006)]. This has the advantage of carrying over accumulated expertise based on the SRK model while gaining the benefits of Wertheim's theory when necessary. A related alternative is the ESD model [S. J. Suresh, J. R. Elliott, *Ind. Eng. Chem. Res.* **31:** 2783 (1992)], which naturally reduces to a cubic equation in the absence of association. When molecules in a mixture have similar site types such that the geometric mean of the association constants can be used for cross-interactions, computational efficiency can be improved [J. R. Elliott, *Ind. Eng. Chem. Res.* **35:** p. 1624, (1996)], which sacrifices slightly on generality but is roughly 3 times faster for binary mixtures, and much faster for multicomponent mixtures.

At present, SAFT models are superior to cubic equations for mixtures involving molecules with high molecular weights, above about 1200 g/mol. Readers should be careful to validate the model as implemented in their software of choice. Check that parameters are available for the components of interest, especially the association parameters. As always, include comparison of the model to experimental data for as many systems as are available.

### LIQUID-PHASE PROPERTIES

The simplicity and generality of Eq. (4-26) recommend it when properties need to be computed consistently for streams that may contain mixed phases and reactive compositions, and modern equations of state can provide accurate characterizations of vapor-liquid transitions. However, calculation of property changes from one liquid state to another can be based on Eqs. (4-40) and (4-41) where the pressure-dependent contributions are either ignored or treated as small corrections. The main challenge for mixtures is to estimate the properties with greater accuracy than can be obtained from the pathway of Eq. (4-26).

## SYSTEMS OF VARIABLE COMPOSITION

The composition of a system may vary because the system is open or because of chemical reactions even in a closed system. The equations developed here apply regardless of the cause of composition changes. The objectives of this analysis are twofold: (1) to enable more accurate estimation of mixed stream properties with Eq. (4-26) through a more detailed treatment of departure functions and heats of mixing and (2) to articulate the necessary relations for evaluating the activities of components in mixtures.

While computations of thermodynamic properties such as *U*, *H*, and *S* dominate in the analysis of processes involving pure compounds, processes involving mixtures tend to focus foremost on computing the equilibrium phase behavior. State conditions such as *T*, *P* that lead to a vapor phase at one composition may yield a liquid at another composition, so determining the state(s) of the phase(s) in question is not as straightforward as for single-component systems. Occasionally, paradoxical quantities are encountered, such as the liquid solubility of a "noncondensable" gas. Computation of bulk phase thermodynamic properties is straightforward once the phase behavior has been resolved.

Coverage of mixtures begins with a review of fundamentals. Briefly, the Gibbs energy is minimized at equilibrium, suggesting the importance of derivative properties. This leads to the formulation of phase and reaction equilibrium criteria. These criteria are general, but they require models of the Gibbs energy for implementation. The two classes of models most commonly used are equations of state and activity models. Activity models are quite successful for modeling in most common industrial situations. Therefore, we cover first activity models and then EOSs. We return to Henry's law after EOSs to facilitate discussion of how gaseous species are treated in the two approaches.

### CHEMICAL POTENTIAL

For an *open* single-phase system, we add the dependence of energy on composition, $nU=\underline{U}(nS, nV, n_1, n_2, n_3, \ldots)$. In consequence,

$$d(nU)=T\,d(nS)-P\,d(nV)+\sum_i\left[\frac{\partial(nU)}{\partial n_i}\right]_{nS,nV,n_{j\neq i}} dn_i \tag{4-97}$$

where the summation is over all species present in the system and subscript $n_{j\neq i}$ indicates that all mole numbers are held constant except the $i^{\text{th}}$. Equation (4-97) is the *fundamental property relation* for mixed single-phase *PVT* systems, from which all other equations connecting properties of such systems are derived. The partial derivative in Eq. (4-97) has special significance for phase equilibria in mixtures, and it is called the *chemical potential.* Treatment of the other basic properties *H, A,* and *G* results in similar relations, the most important of which is

$$d(nG)=-nS\,dT+nV\,dP+\sum_i\left(\frac{\partial(nG)}{\partial n_i}\right)_{T,P,n_{j\neq i}} dn_i \tag{4-98}$$

where chemical potential is given equivalently by

$$\mu_i\equiv\left(\frac{\partial(nU)}{\partial n_i}\right)_{nS,nV,n_{j\neq i}}=\left(\frac{\partial(nG)}{\partial n_i}\right)_{T,P,n_{j\neq i}} \tag{4-99}$$

## PARTIAL MOLAR PROPERTIES

For a homogeneous *PVT* system composed of any number of chemical species, let symbol $M$ represent the molar value of an extensive thermodynamic property, say, $U$, $H$, $S$, $A$, or $G$. The extensive quantity can be expressed as

$$nM = \underline{M}(T, P, n_1, n_2, n_3, \ldots)$$

Their derivatives at constant $T$, $P$ and all $n$ except $i$ are given the generic symbol $\bar{M}_i$ and are defined as a *partial molar property* by

$$\bar{M}_i \equiv \left[\frac{\partial(nM)}{\partial n_i}\right]_{T,P,n_{j\neq i}} \tag{4-100}$$

where the derivative constraints are part of the definition. A result of this definition is that the molar property can be obtained by

$$M = \sum_i x_i \bar{M}_i \qquad \text{and} \qquad nM = \sum_i n_i \bar{M}_i \tag{4-101}$$

The definition of a partial molar quantity can be applied to all intensive properties yielding the partial-property relations

$$\bar{H}_i = \bar{U}_i + P\bar{V}_i \qquad \bar{A}_i = \bar{U}_i - T\bar{S}_i \qquad \bar{G}_i = \bar{H}_i - T\bar{S}_i$$

These equations illustrate the parallelism that exists between the equations for a constant-composition solution and those for the corresponding partial properties. This parallelism exists whenever the solution properties in the parent equation are related linearly (in the algebraic sense). The partial molar Gibbs energy should be recognized as the *chemical potential*, $\mu$.

**The Gibbs-Duhem Equation** Partial molar quantities must satisfy the Gibbs-Duhem relation [cf. Tester and Modell (1997)]

$$\left(\frac{\partial M}{\partial T}\right)_{P,x} dT + \left(\frac{\partial M}{\partial P}\right)_{T,x} dP - \sum_i x_i \, d\bar{M}_i = 0 \tag{4-102}$$

Frequently, the first two terms are small, resulting in the approximate relation

$$\sum_i x_i \, d\bar{M}_i = 0 \qquad \text{(constant } T, P\text{)} \tag{4-103}$$

## PROPERTIES OF IDEAL GAS MIXTURES

The ideal gas mixture model is useful because it is molecularly based, is analytically simple, is realistic in the limit of zero pressure, and provides a conceptual basis for solution thermodynamics. A simple molar average applies for internal energy, $U$, and volume, $V$, and thus enthalpy, $H = U + PV$,

$$M^{ig} = \sum_i y_i \, M_i^{ig} \tag{4-104}$$

where $M^{ig}$ can represent $U$, $V$, or $H$. For the entropy an additional term is required to account for the distinguishability of species in a mixture:

$$S^{ig} = \sum_i y_i \, S_i^{ig} - R \sum_i y_i \ln y_i \tag{4-105}$$

For the Gibbs energy, $G^{ig} = H^{ig} - TS^{ig}$ whence by Eqs. (4-104) and (4-105)

$$G^{ig} = \sum_i y_i \, G_i^{ig} + RT \sum_i y_i \ln y_i \tag{4-106}$$

The ideal gas model may serve as a reasonable approximation to reality under conditions indicated by Eq. (4-21), where molar averages are applied to the critical properties.

Chemical potential for an ideal gas is obtained by applying Eq. (4-100)

$$\mu_i^{ig} \equiv \bar{G}_i^{ig} = G_i^{ig} + RT \ln y_i \tag{4-107}$$

Elimination of $G_i^{ig}$ from this equation is accomplished through Eq. (4-38), written for pure species $i$ as an ideal gas at the temperature of the system:

$$dG_i^{ig} = V_i^{ig} \, dP = \frac{RT}{P} dP = RT \, d \ln P \qquad \text{(constant } T\text{)}$$

Integration at constant temperature and standard state pressure $P^\circ$ gives

$$G_i^{ig} = \Gamma_i(T) + RT \ln P \tag{4-108}$$

where the integration constant $\Gamma_i(T)$ includes $RT \ln P^\circ$ and is a function of temperature and standard state pressure only. Equation (4-107) now becomes

$$\mu_i^{ig} = \bar{G}_i^{ig} = \Gamma_i(T) + RT \ln (y_i P) \tag{4-109}$$

leading to

$$G^{ig} = \sum_i y_i \Gamma_i(T) + RT \sum_i \ln (y_i P) \tag{4-110}$$

A dimensional ambiguity is implied with Eqs. (4-108) through (4-110) in that $P$ has units, whereas ln $P$ must be dimensionless. Although the units cancel with the standard state pressure, in practice this is of no consequence, because only *differences* in Gibbs energy appear, along with *ratios* of the quantities with units of pressure in the arguments of the logarithm. Consistency in the units of pressure is, of course, required; if the standard state is 1 bar, use bars for all computations involving reactions.

## COMPONENT FUGACITY

The definition of the fugacity of a species in solution is parallel to the definition of the pure-species fugacity. An equation analogous to the ideal gas expression, Eq. (4-109), is written for species $i$ in a fluid mixture

$$\mu_i \equiv \Gamma_i(T) + RT \ln \hat{f}_i \tag{4-111}$$

where the partial pressure $y_i P$ is replaced by $\hat{f}_i$, the fugacity of species $i$ in solution. Because it is not a partial property, it is identified by a circumflex rather than an overbar. The fugacity of an ideal gas component is apparent by comparing Eqs. (4-111) and (4-109):

$$\hat{f}_i^{ig} = y_i P \tag{4-112}$$

**Ideal Solution Model and Henry's Law** The ideal gas model is useful as a standard of comparison for real gas behavior. This is formalized through departure functions. The *ideal solution* is similarly useful as a standard to which real solution behavior may be compared and is common for liquid solutions.

The partial molar Gibbs energy or chemical potential of species $i$ in an ideal gas mixture is given by Eq. (4-107), written as

$$\mu_i^{ig} = \bar{G}_i^{ig} = G_i^{ig}(T, P) + RT \ln y_i$$

This equation takes on new meaning when $G_i^{ig}(T, P)$ is replaced by $G_i(T, P)$, the Gibbs energy of pure species $i$ in its *real physical state* of gas, liquid, or solid at the mixture $T$ and $P$. The ideal solution is therefore *defined* as one for which

$$\mu_i^{id} = \bar{G}_i^{id} \equiv G_i(T, P) + RT \ln x_i \tag{4-113}$$

where superscript id denotes an ideal solution property and $x_i$ represents the mole fraction because application is usually to liquids.

This relation requires

$$\bar{V}_i^{id} = V_i; \qquad \bar{U}_i^{id} = U_i \tag{4-114}$$

and

$$\bar{S}_i^{id} = S_i - R \ln x_i \tag{4-115}$$

Because $\bar{H}_i^{id} = \bar{G}_i^{id} + T\bar{S}_i^{id}$, substitutions by Eqs. (4-113) and (4-115) yield

$$\bar{H}_i^{id} = H_i \tag{4-116}$$

The mixture property can be calculated by the mole-fraction-weighted sum of partial molar properties, Eq. (4-101). For the special case of an ideal solution, incorporating Eqs. (4-113) through (4-116) gives:

$$G^{id} = \sum_i x_i G_i + RT \sum_i x_i \ln x_i \tag{4-117}$$

$$V^{id} = \sum_i x_i V_i \tag{4-118}$$

$$S^{id} = \sum_i x_i S_i - R \sum_i x_i \ln x_i \tag{4-119}$$

$$H^{id} = \sum_i x_i H_i \tag{4-120}$$

A simple equation for the fugacity of a species in an ideal solution follows. For the special case of species $i$ in an ideal solution, Eq. (4-113) becomes

$$\mu_i^{id} = \bar{G}_i^{id} = \Gamma_i(T) + RT \ln \hat{f}_i^{id} \tag{4-121}$$

When this equation and Eq. (4-111) are combined with Eq. (4-117), $\Gamma_i(T)$ is eliminated, and the resulting expression reduces to

$$\hat{f}_i^{id} = x_i f_i \tag{4-122}$$

This equation, known as the *Lewis-Randall rule*, shows that the fugacity of each species in an ideal solution is proportional to its mole fraction; the proportionality constant is the fugacity of *pure* species $i$ in the same physical state as the solution and at the same $T$ and $P$. Division of both sides of Eq. (4-122) by $x_i P$ and substitution of $\hat{\phi}_i^{id}$ for $\hat{f}_i^{id}/x_i P$ [Eq. (4-130)] and of $\phi_i$ for $f_i/P$ [Eq. (4-64)] give the alternative form for equations of state

$$\hat{\phi}_i^{id} = \phi_i \tag{4-123}$$

Thus the fugacity coefficient of species $i$ in an ideal solution equals the fugacity coefficient of *pure* species $i$ in the same physical state as the solution and at the same $T$ and $P$. Ideal solution behavior is often approximated by solutions composed of molecules not too different in size and of the same chemical nature. Thus, a mixture of isomers conforms very closely to ideal solution behavior. So do mixtures of adjacent members of a homologous series.

An alternative ideal solution results when the standard state is at infinite dilution rather than at purity, which results in the Henry law ideal solution, here written using the Henry volatility constant common in chemical engineering literature:

$$\hat{f}_i^{id} = x_i h_i \tag{4-124}$$

While Eqs. (4-122) and (4-124) hint that $h_i$ and $f_i$ might be the same, they are equal only when a solution follows ideal solution behavior at all compositions, which is rare. Henry's law is named after the English chemist who examined the solubilities of gases in water in the early 19th century [*Phil. Trans. R. Soc. Lond.* **93:** pp. 29 and 274 (1803)].

In casual terms we would state that the concentration of a dissolved solute in a liquid is proportional to its partial pressure in the vapor phase, and the proportionality constant, at a given temperature, is referred to as Henry's "constant" (although it varies with temperature). Formally, Henry's law can be expressed as a limiting fugacity

$$h_i = \lim_{x_i \to 0} \frac{\hat{f}_i}{x_i} \tag{4-125}$$

where $\hat{f}_i$ is the fugacity of component $i$ and $x_i$ is its liquid mole fraction. Application of the rigorous limit is often a problem in practice, and hence other considerations need to be adopted. For example, a reference fluid of pure sodium ions would be impractical when concerned with salt solutions.

Over the past two centuries, scientists and engineers have built upon Henry's seminal discovery to develop a comprehensive theoretical framework and extensive databases for the correlation of solute solubilities over a wide range of temperature, pressure, and liquid- and vapor-phase concentrations. This background is presented in the section following discussion of activity models.

## PHASE EQUILIBRIA CRITERIA

The criteria for internal thermal and mechanical equilibrium simply require uniformity of temperature and pressure throughout the system. The criteria for phase equilibria at constant $T$ and $P$ require that the Gibbs energy for the overall system be minimized. For a two-phase system, each phase taken separately is an *open* system, capable of exchanging mass with the other. The criteria for phase equilibria are derived in textbooks. The general result is

$$\mu_i' = \mu_i'' = \mu_i''' = \cdots \tag{4-126}$$

Substitution for each $\mu_i$ by Eq. (4-111) produces the equivalent result:

$$\hat{f}_i' = \hat{f}_i'' = \hat{f}_i''' = \cdots \tag{4-127}$$

These are the criteria of phase equilibrium applied in the solution of practical problems.

For the case of equilibrium with respect to chemical reaction within a single-phase closed system, at constant $T$ and $P$, Eq. (4-98) simplifies to

$$\sum_i \mu_i \, dn_i = 0 \tag{4-128}$$

For a system in which both phase and chemical reaction equilibrium prevail, the criteria of Eqs. (4-127) and (4-128) are superimposed.

## PHASE RULE

The *intensive* state of a *PVT* system is established when its temperature and pressure and the compositions of all phases are fixed. However, for equilibrium states not all these variables are independent, and fixing a limited number of them automatically establishes the others. This number of independent intensive variables is given by the phase rule, and it is called the *number of degrees of freedom* of the system. It is the number of variables that may be arbitrarily specified and that must be so specified in order to fix the *intensive* state of a system at equilibrium. This number is the difference between the number of variables needed to characterize the system and the number of equations that may be written connecting these variables.

For a system containing $N$ chemical species distributed at equilibrium among $\pi$ phases, the phase rule variables are $T$ and $P$, presumed uniform throughout the system, and $N-1$ mole fractions in each phase. The number of these variables is $2 + (N-1)\pi$. The masses of the phases are not phase rule variables, because they have nothing to do with the intensive state of the system.

The equilibrium equations that may be written to express chemical potentials or fugacities as functions of $T$, $P$, the phase compositions, and the phase rule variables:

1. Equation (4-127) for each species, giving $(\pi - 1)N$ phase equilibrium equations
2. Equation (4-128) for each independent chemical reaction, giving $r$ equations

The total number of independent equations is therefore $(\pi - 1)N + r$. Because the degrees of freedom $F$ is the difference between the number of variables and the number of equations,

$$F = 2 + (N-1)\pi - (\pi - 1)N - r$$

or

$$F = 2 - \pi + N - r \tag{4-129}$$

The number of independent chemical reactions $r$ can be determined as follows:

1. Write *formation* reactions from the elements for each chemical compound present.
2. Combine these reaction equations so as to eliminate from the set all elements not present as elements in the system. A systematic procedure is to select one equation and combine it with each of the other equations of the set so as to eliminate a particular element. This usually reduces the set by one equation for each element eliminated, although two or more elements may be simultaneously eliminated.

The resulting set of $r$ equations is a complete set of independent reactions. More than one such set is often possible, but all sets number $r$ and are equivalent.

***Example 4-8 Application of the Phase Rule*** Consider the following cases.

*a.* For a system of two miscible nonreacting species in vapor/liquid equilibrium,

$$F = 2 - \pi + N - r = 2 - 2 + 2 - 0 = 2$$

The 2 degrees of freedom for this system may be satisfied by setting $T$ and $P$, or $T$ and $y_1$, or $P$ and $x_1$, or $x_1$ and $y_1$, etc., at fixed values. Thus for equilibrium at a particular $T$ and $P$, this state (if possible at all) exists only at one liquid and one vapor composition. Once the 2 degrees of freedom are used up, no further specification is possible that would restrict the phase rule variables. For example, one cannot *in addition* require that the system form an azeotrope (assuming this is possible), for this requires $x_1 = y_1$, an equation not taken into account in the derivation of the phase rule. Thus the requirement that the system form an azeotrope imposes a special constraint, making $F = 1$.

*b.* For a gaseous system consisting of CO, $CO_2$, $H_2$, $H_2O$, and $CH_4$ in chemical reaction equilibrium,

$$F = 2 - \pi + N - r = 2 - 1 + 5 - 2 = 4$$

The value of $r = 2$ is found from the formation reactions:

$$C + \tfrac{1}{2}O_2 \rightarrow CO \qquad C + O_2 \rightarrow CO_2$$

$$H_2 + \tfrac{1}{2}O_2 \rightarrow H_2O \qquad C + 2H_2 \rightarrow CH_4$$

Systematic elimination of C and $O_2$ from this set of chemical equations reduces the set to 2. Three possible pairs of equations may result, depending on how the combination of equations is effected. Any *pair* of the following three equations represents a complete set of independent reactions, and all pairs are equivalent.

$$CH_4 + H_2O \rightarrow CO + 3H_2$$

$$CO + H_2O \rightarrow CO_2 + H_2$$

$$CH_4 + 2H_2O \rightarrow CO_2 + 4H_2$$

The result, $F = 4$, means that one is free to specify, for example, $T$, $P$, and two mole fractions in an equilibrium mixture of these five chemical species, provided nothing else is arbitrarily set. Thus it cannot simultaneously be required that the system be prepared from specified amounts of particular constituent species.

## APPROACHES FOR PHASE AND REACTION EQUILIBRIA MODELING

**Component Fugacity and Activity Coefficients** While Eqs. (4-126) to (4-128) form the basis of phase and chemical equilibria, they do not dictate the methods to be used to calculate the properties of the phases. Acknowledging that equilibria can be expressed in terms of chemical potential or fugacity, chemical engineering practice has evolved to use fugacity. We express the fugacity of the real gas or liquid relative to one of the idealized states (ideal gas, Lewis-Randall ideal solution, or Henry's law ideal solution). When the fugacity is calculated relative to the ideal gas, the departure function is used, resulting in the component *fugacity coefficient*. Subtracting Eq. (4-107) from Eq. (4-111), both written for the same temperature, pressure, and composition, yields after including (4-108)

$$\mu_i - \mu_i^{ig} = RT \ln \frac{\hat{f}_i}{y_i P} \equiv RT \ln \hat{\phi}_i \tag{4-130}$$

where by definition $\hat{\phi}_i \equiv \hat{f}_i / (y_i P)$, or

$$\hat{f}_i = y_i \hat{\phi}_i P \tag{4-131}$$

The dimensionless ratio $\hat{\phi}_i$ is called the *fugacity coefficient of species i in solution*.

Using the Lewis-Randall rule, typically for condensed phases and thus the use of $x$ gives

$$\hat{f}_i^{\text{cond}} = x_i \gamma_i f_i^{\text{cond}} = x_i \gamma_i \phi_i^{\text{sat}} P_i^{\text{sat}} \exp\left(\frac{V_i^{\text{cond}}(P - P_i^{\text{sat}})}{RT}\right) \tag{4-132}$$

where the activity coefficient $\gamma_i$ characterizes the deviations from an ideal solution and $f_i^{\text{cond}}$ is given by Eq. (4-67). For Henry's law volatility constant, typically used for liquid phases,

$$\hat{f}_i^{L} = h_i(T, P_i^o) x_i \gamma_i^* \exp\left(\int_{P_i^o}^{P} \frac{\overline{v}_i^{\infty}}{RT} dP\right) \tag{4-133}$$

The activity coefficient $\gamma_i^*$ of Eq. (4-133) is related, but not equal to the activity coefficient $\gamma_i$ in Eq. (4-132) as discussed later in Eq. (4-199).

For the EOS approach, we use Eq. (4-131) for both vapor and liquid phases, resulting in

$$\hat{\phi}_i^V y_i = \hat{\phi}_i^L x_i \tag{4-134}$$

This introduces compositions $x_i$ and $y_i$ into the equilibrium equations, but neither is explicit, because the $\hat{\phi}_i$ are functions of composition as well as $T$ and $P$. Thus, Eq. (4-134) represents $N$ complex relationships connecting $T$, $P$, $\{\boldsymbol{x}_i\}$, and $\{\boldsymbol{y}_i\}$. The EOS approach is typically successful for nonpolar substances and must be used when fluids are near critical points. Polar substances can be modeled by including association effects or by use of sophisticated mixing rules.

For polar substances the gas phase may be modeled with the EOS approach, while the liquid phase is modeled with deviations from the Lewis-Randall rule. The fugacity of species $i$ in the liquid phase is given by Eq. (4-132), and the vapor-phase fugacity is given by Eq. (4-131). By Eqs. (4-127) and (4-132) the relation becomes

$$\gamma_i x_i \phi_i^{\text{sat}} P_i^{\text{sat}} \exp(V^L(P - P_i^{\text{sat}})/(RT)) = \hat{\phi}_i y_i P \qquad i = 1, 2, \ldots, N \tag{4-135}$$

Identifying superscripts $L$ and $V$ are omitted here with the understanding that $\gamma_i$ is a liquid-phase property, whereas $\hat{\phi}_i$ is a vapor-phase property. Applications of Eq. (4-135) represent the *gamma/phi* approach to VLE calculations, generally applicable below 10 bar.

For Henry's law, we use Eq. (4-131) for the vapor phase and Eq. (4-133) for the liquid phase,

$$\hat{\phi}_i y_i P = h_i(T, P_i^o) x_i \gamma_i^* \exp\left(\int_{P_i^o}^{P} \frac{\overline{v}_i^{\infty}}{RT} dP\right) \tag{4-136}$$

When Henry's law is applied, it is common to use it for some of the components (normally noncondensable components) while using the Lewis-Randall approach, Eq. (4-135), for the remainder of components.

**Excess Properties** An *excess property* $M^E$ is defined as the difference between the actual property value of a solution and the value it would have as an ideal solution at the same $T$, $P$, and composition. Thus,

$$M^E \equiv M - M^{\text{id}} \tag{4-137}$$

where $M$ represents the molar (or unit-mass) value of any extensive thermodynamic property (say, $V$, $U$, $H$, $S$, $G$). This definition is similar to the definition of a departure function as given by Eq. (4-52). However, excess properties have no meaning for pure species, whereas departure functions exist for pure species as well as for mixtures. Partial molar excess properties $\overline{M}_i^E$ are defined analogously:

$$\overline{M}_i^E = \overline{M}_i - \overline{M}_i^{\text{id}} \tag{4-138}$$

Of particular interest is the partial molar excess Gibbs energy. Rewriting Eq. (4-111) as

$$\overline{G}_i = \Gamma_i(T) + RT \ln \hat{f}_i$$

in accord with Eq. (4-122) for an ideal solution, this becomes

$$\overline{G}_i^{\text{id}} = \Gamma_i(T) + RT \ln x_i f_i$$

By differences

$$\overline{G}_i - \overline{G}_i^{\text{id}} = RT \ln \frac{\hat{f}_i}{x_i f_i}$$

The left side is the partial excess Gibbs energy $\overline{G}_i^E$; the dimensionless ratio $\hat{f}_i / x_i f_i$ on the right is the *activity coefficient of species i in solution*, given the symbol $\gamma_i$, and *by definition*,

$$\gamma_i \equiv \frac{\hat{f}_i}{x_i f_i} \tag{4-139}$$

Thus,

$$\overline{G}_i^E = RT \ln \gamma_i \tag{4-140}$$

Comparison with Eq. (4-130) shows that Eq. (4-140) relates $\gamma_i$ to $\overline{G}_i^E$ exactly as Eq. (4-130) relates $\hat{\phi}_i$ to $\overline{G}_i^{\text{dep}}$. For an ideal solution, $\overline{G}_i^E = 0$, and therefore $\gamma_i^{\text{id}} = 1$.

Activity coefficients are key descriptors in the design of chemical separation and reaction operations, liquid product formulations, and other technologies where liquid composition is a key factor affecting performance. In practice, the value of $\gamma_i$ serves as a correction factor for the solute mole fraction concentration $x_i$ to better account for the solute's true chemical potential–driven activity which determines phase equilibrium behavior and reactivity,

$$\mu_i - G_i^{\circ} = RT \ln a_i \tag{4-141}$$

where *activity* is given by $a_i \equiv \hat{f}_i / (f_i^{\circ})$ and for the Lewis-Randall rule, $a_i = \gamma_i x_i$. For a Lewis-Randall ideal solution, $\gamma_i$ is unity; each component acts as if surrounded by its own kind, so phase equilibrium properties are determined according to molar concentration or mole fraction ($a_i = x_i$). For other mixtures, the solute's activity coefficient is usually greater than unity, and the solute behaves as if there is more of it present in the mixture than its mole fraction would indicate ($a_i > x_i$, a *positive* deviation from ideality). This may indicate that solute-solvent interactions are repulsive relative to solvent-solvent interactions or may lead to segregation of the mixture (negative entropic effects). For a vapor-liquid system, such a component has an enhanced tendency to escape from the liquid into the vapor. The solute activity coefficient can also be less than unity such that its effective mole fraction in the mixture is reduced ($a_i < x_i$, a *negative* deviation). This behavior may result from mixing molecules that differ greatly in molecular size (an entropic effect) or by exothermic formation of multicomponent molecular structures

or complexes in solution. The activity coefficient is used to quantify a deviation from ideal mixture behavior, although often the molecular mechanisms responsible for the observed deviation are not fully understood.

The *infinite-dilution* (or limiting) activity coefficient $\gamma_{ij}^{\infty} = \lim_{x_i \to 0} \gamma_i$ is a particularly useful quantity because it represents nonideal interactions for a solute *i* completely surrounded by solvent *j*. Its value normally is the most extreme $\gamma_i$ value for a given binary, and so it serves to characterize the nonideality of the mixture. The limiting activity coefficient is related to the partial molar excess Gibbs energy involved in moving a molecule of solute *i* from its pure liquid reference state into a pool of solvent *j* molecules:

$$RT \ln \gamma_{ij}^{\infty} = \overline{G}_{ij}^{E,\infty} = \overline{H}_{ij}^{E,\infty} - T\overline{S}_{ij}^{E,\infty} \tag{4-142}$$

Once a value for $\gamma_{ij}^{\infty}$ has been determined, by either experiment or prediction, values at other compositions can be estimated by extrapolation using a suitable correlation equation such as those discussed below. In many cases, knowledge of $\gamma_{ij}^{\infty}$ for all binary pairs allows reliable extrapolation to higher concentrations in multicomponent mixed solution—with results suitable for many applications or at least for initial screening studies. In special cases, data for ternary or higher numbers of components in solution may be needed to improve the correlation for final design purposes, especially for systems with unusually strong multicomponent intermolecular interactions or strong association of molecules of the same kind. A database of over 4000 values of $\gamma_{ij}^{\infty}$ has been published by Lazzaroni et al. [*Ind. Chem. Eng. Res.* **44:** 4075–4083 (2005)].

**Property Changes of Mixing** A *property change of mixing* is defined by

$$\Delta M \equiv M - \sum_i x_i M_i \tag{4-143}$$

where *M* represents a molar thermodynamic property of a homogeneous solution and $M_i$ is the molar property of pure species *i* at the *T* and *P* of the solution and in the same physical state. In addition, $\Delta G$, $\Delta V$, $\Delta S$, and $\Delta H$ are the Gibbs energy change of mixing, the volume change of mixing, the entropy change of mixing, and the enthalpy change of mixing, respectively. Applications are usually to liquids.

Each of Eqs. (4-117) through (4-120) is an expression for an ideal solution property, and each may be combined with the defining equation for an excess property. For an ideal solution, each excess property is zero.

Property changes of mixing and excess properties are easily calculated one from the other. The most common property changes of mixing are the volume change of mixing $\Delta V$ and the enthalpy change of mixing $\Delta H$, commonly called the *heat of mixing*. These properties are identical to the corresponding excess properties. Moreover, they are directly measurable, providing an experimental entry into the network of equations of solution thermodynamics.

**Excess and Departure Property Relations** Equations for excess properties are developed in much the same way as those for departure properties. The following equations are in complete analogy to those for departure properties:

$$\frac{V^E}{RT} = \left[\frac{\partial (G^E/RT)}{\partial P}\right]_{T,x} \tag{4-144}$$

$$\frac{H^E}{RT} = -T\left[\frac{\partial (G^E/RT)}{\partial T}\right]_{P,x} \tag{4-145}$$

$$\ln \gamma_i = \left[\frac{\partial n(G^E/RT)}{\partial n_i}\right]_{T,P,n_{j\neq i}} \tag{4-146}$$

This last equation demonstrates that $\ln \gamma_i$ is a partial property with respect to $G^E/RT$, implying also the sum of mole-fraction-weighted partial molar properties to give the excess Gibbs energy can be written using activity coefficients

$$\frac{G^E}{RT} = \sum_i x_i \ln \gamma_i \tag{4-147}$$

$$\left(\frac{\partial \ln \gamma_i}{\partial P}\right)_{T,x} = \frac{\overline{V}_i^E}{RT} \tag{4-148}$$

$$\left(\frac{\partial \ln \gamma_i}{\partial T}\right)_{P,x} = -\frac{\overline{H}_i^E}{RT^2} \tag{4-149}$$

Equation (4-149) is a version of the Gibbs-Helmholtz equation. For a detailed discussion of the origins of this equation, see Mathias [*Ind. Eng. Chem. Res.* **55:** 1076–1087 (2016)]. Analogous to Eqs. (4-144) and (4-145), we can write

$$\frac{V^{\text{dep}}}{RT} = \left[\frac{\partial (G^{\text{dep}}/RT)}{\partial P}\right]_{T,x} \tag{4-150}$$

$$\frac{H^{\text{dep}}}{RT} = -T\left[\frac{\partial (G^{\text{dep}}/RT)}{\partial T}\right]_{P,x} \tag{4-151}$$

Also implicit in Eq. (4-130) is the relation

$$\ln \hat{\phi}_i = \left[\frac{\partial n(G^{\text{dep}}/RT)}{\partial n_i}\right]_{T,P,n_{j\neq i}} \tag{4-152}$$

This equation demonstrates that $\ln \hat{\phi}_i$ is a partial property with respect to $G^{\text{dep}}/RT$. The sum of the mole-fraction-weighted partial molar properties to give the mixture property, relation (4-101), therefore applies, and

$$\frac{G^{\text{dep}}}{RT} = \sum_i x_i \ln \hat{\phi}_i \tag{4-153}$$

Recognizing $\ln \hat{\phi}_i$ as a partial property leads to

$$\left(\frac{\partial \ln \hat{\phi}_i}{\partial P}\right)_{T,x} = \frac{\overline{V}_i^{\text{dep}}}{RT} \tag{4-154}$$

$$\left(\frac{\partial \ln \hat{\phi}_i}{\partial T}\right)_{P,x} = -\frac{\overline{H}_i^{\text{dep}}}{RT^2} \tag{4-155}$$

**Component Fugacity Coefficients from an EOS** Equation (4-152) can be applied readily only to departure functions explicit in *T* and *P*. For departure functions explicit in *T* and *V*, such as a cubic equation of state, an alternative method is used:

$$\ln \hat{\phi}_i = \left[\frac{\partial n(A^{\text{dep}}/RT)}{\partial n_i}\right]_{T,V,n_{j\neq i}} - \ln Z \tag{4-156}$$

***Example 4-9 Derivation of Fugacity Coefficient Expressions*** Application of Eq. (4-152) to an expression giving $G^{\text{dep}}$ as a function of composition yields an equation for $\ln \hat{\phi}_i$. In the simplest case of a gas mixture for which the virial equation [Eqs. (4-69) and (4-71)] is appropriate, Eq. (4-61) provides the relation

$$\frac{nG^{\text{dep}}}{RT} = \frac{P}{RT}(nB)$$

Differentiation in accord with Eqs. (4-152) yields

$$\frac{RT \ln \hat{\phi}_i}{P} = \left[\frac{\partial (nB)}{\partial n_i}\right]_{T,n_{j\neq i}} = \left[\frac{\partial \left(1/n \sum\sum n_k n_j B_{kj}\right)}{\partial n_i}\right]_{T,n_{j\neq i}} = 2\sum_1^n y_j B_{ij} - B \tag{4-157}$$

For EOSs involving $Z(T, V)$ such as cubic EOSs, the differentiation follows Eq. (4-156). For example, when the mixing and combining rules follow Eqs. (4-86) to (4-88) as nondimensionalized by Eq. (4-92), the component fugacity coefficient for the PR EOS is given by

$$\ln \hat{\phi}_i^{\alpha} = \ln\left(\frac{f_i^{\alpha}}{y_i P}\right) = \frac{B_i}{B^{\alpha}}(Z^{\alpha} - 1) - \ln(Z^{\alpha} - B^{\alpha}) - \frac{A^{\alpha}}{B^{\alpha}\sqrt{8}}\left(\frac{2\Sigma z_j A_{ij}}{A^{\alpha}} - \frac{B_i}{B^{\alpha}}\right)\ln\left[\frac{Z^{\alpha} + (1+\sqrt{2})B^{\alpha}}{Z^{\alpha} + (1-\sqrt{2})B^{\alpha}}\right] \tag{4-158}$$

where α indicates the phase (that is, *V* or *L*) and $z_j$ indicates the mole fraction in that phase (typically $y_j$ for vapor and $x_j$ for liquid). The *A* here is not Helmholtz energy and *B* here is not the virial coefficient. Although the formula is the same for all phases, the values of $Z^V$ and $Z^L$ are naturally quite distinct. Similarly, $A^V$, $A^L$ and $B^V$, and $B^L$ differ owing to compositions. Standard texts describe this derivation in detail.

## CORRELATIVE MODELS FOR THE EXCESS GIBBS ENERGY

Excess properties find application in the treatment of liquid solutions. The excess volume for liquid mixtures is usually small, and in accord with Eq. (4-144) the pressure dependence of $G^E$ is usually ignored. Thus, engineering efforts to model $G^E$ center on representing its composition and

temperature dependence. For educational purposes, $G^E$ models such as the Redlich-Kister expansion, Margules models, and the van Laar model are typically covered, but these are simple empirical or semiempirical relations that are best applied to binary systems. Since most realistic applications focus on multicomponent systems, we focus our discussion here on multicomponent $G^E$ models. All of these are typically available in chemical process simulators.

**Margules, Wilson, NRTL, UNIQUAC** When experimental data are available for a system of interest, correlative models are preferred over predictive models if the quality of the data is high. We provide in later sections some recommendations for assessing data by evaluating trends in homologous series of compounds. Methods used to assess thermodynamic consistency are discussed by Kang et al. [*J. Chem. Eng. Data* **55:** 3631 (2010)]. If pure component vapor pressure data are in error, the thermodynamic consistency tests and reliability of the resulting model for multicomponent mixtures likely will be poor. Two subsections immediately following this one address sources of data and methods of reducing the data to relevant model parameters. Four $G^E$ models are applied to correlation most often, most based on the concepts of local compositions and Lewis-Randall activity coefficients: the Margules model, the Wilson model, the NRTL model, and the UNIQUAC model. To illustrate the general form of each model, in the discussion that follows formulas are listed for the activity coefficients of a binary mixture and evaluated for 1-propanol and water at 120°C as an example.

***Margules Equation*** The *Margules equation* is empirical. It is typically equivalent to the Redlich-Kister expansion in its one- to three-parameter form. The two-parameter Gibbs excess energy and activity coefficients can be written as

$$\frac{G^E}{RT} = x_1 x_2 (A_{21} x_1 + x_2 A_{12}) \tag{4-159}$$

$$\ln \gamma_1 = x_2^2 (A_{12} + 2(A_{21} - A_{12}) x_1) \tag{4-160}$$

$$\ln \gamma_2 = x_1^2 (A_{21} + 2(A_{12} - A_{21}) x_2) \tag{4-161}$$

For a mixture of 20 mol% propanol in water: $A_{12}$ = 1.164; $A_{21}$ = 2.244; $\gamma_1$ = 2.777; and $\gamma_2$ = 1.021. The Margules two-parameter model reduces to the one-parameter model when $A_{12} = A_{21}$. The most common extension of the Margules model to multicomponent mixtures is Wohl's expansion [cf. Prausnitz, Lichtenthaler, and de Azevedo (1999, Sec. 6.14)]. Extension of polynomial models for $G^E$ to multicomponent mixtures must be done carefully because the expression for $G^E$ must be invariant to division into identical subcomponents [Michelsen and Kistenmacher, *Fluid Phase Equilib.* **58:** 229 (1990); Mathias, Klotz, and Prausnitz, *Fluid Phase Equilib.* **67:** 31 (1991)]—the so-called invariance criterion. The Wohl expansion shown in the reference does not violate the invariance criterion. However, when models with higher-order binary summations are used, they should be evaluated to ensure that they do not violate this criterion.

Theoretical developments in the molecular thermodynamics of liquid solution behavior are often based on the concept of *local composition*, presumed to account for the short-range order and nonrandom molecular orientations resulting from differences in molecular size and intermolecular forces. Introduced by G. M. Wilson [*J. Am. Chem. Soc.* **86:** 127–130 (1964)] with the publication of a model for $G^E$, this concept prompted the development of alternative local composition models, most notably the NRTL (non-random two-liquid) equation of Renon and Prausnitz [*AIChE J.* **14:** 135–144 (1968)] and the UNIQUAC (UNIversal QUAsi-Chemical) equation of Abrams and Prausnitz [*AIChE J.* **21**: 116–128 (1975)].

***Wilson Equation*** The *Wilson equation* contains just two parameters per binary system ($a_{ij}$ and $a_{ji}$),

$$\frac{G^E}{RT} = -\sum_i x_i \ln\left(\sum_j x_j \Lambda_{ij}\right) \tag{4-162}$$

$$\ln \gamma_i = 1 - \ln\left(\sum_j x_j \Lambda_{ij}\right) - \sum_k \frac{x_k \Lambda_{ki}}{\sum_j x_j \Lambda_{kj}} \tag{4-163}$$

The temperature dependence of the parameters is estimated by

$$\Lambda_{ij} = \frac{V_j}{V_i} \exp \frac{-a_{ij}}{RT} \qquad i \neq j \tag{4-164}$$

where $V_j$ and $V_i$ are the molar volumes of pure liquids $j$ and $i$, respectively, and $a_{ij}$ is a constant independent of composition and temperature. Molar volumes $V_j$ and $V_i$, themselves weak functions of temperature, form ratios that in practice may be taken as independent of $T$ and are usually evaluated at or near 25°C, $\Lambda_{ij} = 1$ for $i = j$, etc. All indices in these equations refer to the same species, and all summations are over *all* species. For each $i, j$ pair there are two parameters, because $\Lambda_{ij} \neq \Lambda_{ji}$. For example, in a ternary system the three possible $i, j$ pairs are associated with the parameters $\Lambda_{12}$, $\Lambda_{21}$; $\Lambda_{13}$, $\Lambda_{31}$; and $\Lambda_{23}$, $\Lambda_{32}$. At infinite dilution for a binary mixture,

$$\ln \gamma_{1,2}^{\infty} = -\ln \Lambda_{12} + 1 - \Lambda_{21}; \quad \ln \gamma_{2,1}^{\infty} = -\ln \Lambda_{21} + 1 - \Lambda_{12}$$

By Eq. 4-164, both $\Lambda_{12}$ and $\Lambda_{21}$ must be positive numbers. These binary relations may be helpful when inferring values of the parameters from experimental data. For a mixture of 20 percent propanol in water, $a_{12}$ = 3793 J/mol; $a_{21}$ = 5844; $V_1$ = 18.76; $V_2$ = 85.71; $\gamma_1$ = 2.561; and $\gamma_2$ = 1.168. The Wilson equation has a well-known limitation owing to the positive nature of Eq. (4-164); it cannot correlate liquid-liquid equilibria (LLE). This can be an advantage for systems that exhibit large positive deviations from ideality, but do not exhibit LLE. More often it is a disadvantage because most systems with such nonideality do phase-separate at some set conditions.

***NRTL Equation*** The *NRTL equation* contains three parameters for a binary system and is written in multicomponent form as [C. Cohen and H. Renon, *Canadian J. Chem. Eng.* **48:** 291–296 (1970)]

$$\frac{G^E}{RT} = \sum_i x_i \frac{\sum_j x_j \tau_{ji} G_{ji}}{\sum_k x_k G_{ki}} \tag{4-165}$$

$$\ln \gamma_i = \frac{\sum_j x_j \tau_{ji} G_{ji}}{\sum_k x_k G_{ki}} + \sum_j \frac{x_i G_{ij}}{\sum_k x_k G_{kj}} \left( \tau_{ij} - \frac{\sum_m x_m \tau_{mj} G_{mj}}{\sum_k x_k G_{kj}} \right) \tag{4-166}$$

where $G$ and $\tau$ are intermediate variables. Here $i$ identifies the species, and $j$, $k$, $m$ are dummy variables.

$$G_{ij} = \exp(-\alpha_{ij} \tau_{ij}) \tag{4-167}$$

and $\alpha_{12} = \alpha_{21} \equiv \alpha$ for a single binary; $\tau_{12} = \dfrac{b_{12}}{RT}$; $\tau_{21} = \dfrac{b_{21}}{RT}$

where $\alpha$, $b_{12}$, and $b_{21}$, parameters specific to a particular pair of species, are independent of composition and temperature. The infinite-dilution values of binary activity coefficients are

$$\ln \gamma_{1,2}^{\infty} = \tau_{21} + \tau_{12} \exp(-\alpha \tau_{12}) \qquad \ln \gamma_{2,1}^{\infty} = \tau_{12} + \tau_{21} \exp(-\alpha \tau_{21})$$

For 20 percent propanol in water with $\alpha$ = 0.3: $b_{12}$ = 75.3 J/mol; $b_{21}$ = 7259; $\gamma_1$ = 2.772; and $\gamma_2$ = 1.131.

***UNIQUAC Equation*** The *UNIQUAC equation* treats $G^E/RT$ as made up of two additive parts, a *combinatorial* term $G^{\text{comb}}$, accounting for molecular size and shape differences, and a *residual* term $G^{\text{res}}$ (which is not the same as "residual property," i.e., departure function), accounting for molecular interactions:

$$G^E = G^{\text{comb}} + G^{\text{res}} \tag{4-168}$$

Function $G^{\text{comb}}$ contains pure-species parameters only, whereas function $G^{\text{res}}$ incorporates two binary parameters for each pair of molecules. For a multicomponent system,

$$\frac{G^{\text{comb}}}{RT} = \sum_i x_i \ln \frac{\Phi_i}{x_i} + 5 \sum_i q_i x_i \ln \frac{\theta_i}{\Phi_i} \tag{4-169}$$

$$\frac{G^{\text{res}}}{RT} = -\sum_i q_i x_i \ln \left( \sum_j \theta_j \tau_{ji} \right) \tag{4-170}$$

where $q$ is a relative surface area of the molecule and $r$ is the relative molecular volume.

$$\Phi_i \equiv \frac{x_i r_i}{\sum_j x_j r_j}; \quad \theta_i \equiv \frac{x_i q_i}{\sum_j x_j q_j} \tag{4-171}$$

Subscript $i$ identifies species, and $j$ is a dummy index; all summations are over all species. Note that $\tau_{ji} \neq \tau_{ij}$; nevertheless, when $i = j$, then $\tau_{ii} = \tau_{jj} = 1$. In these equations $r_i$ (a relative molecular volume) and $q_i$ (a relative molecular surface area) are pure-species constants. The influence of temperature on $G^E/RT$ enters through the interaction parameters $\tau_{ji}$ of Eq. (4-170), which are temperature-dependent:

$$\tau_{ji} = \exp \frac{-a_{ji}}{RT} \tag{4-172}$$

Parameters for the UNIQUAC equation are therefore values of $a_{ji}$.

An expression for $\ln \gamma_i$ is found by application of Eq. (4-146) to the UNIQUAC model for $G^E/RT$ [Eq. (4-168)]. The result is given by the following equations:

$$\ln \gamma_i = \ln \gamma_i^{\text{comb}} + \ln \gamma_i^{\text{res}} \tag{4-173}$$

$$\ln \gamma_i^{\text{comb}} = 1 - \frac{\Phi_i}{x_i} + \ln \frac{\Phi_i}{x_i} - 5q_i \left( 1 - \frac{\Phi_i}{\theta_i} + \ln \frac{\Phi_i}{\theta_i} \right) \tag{4-174}$$

$$\ln \gamma_i^{\text{res}} = q_i \left( 1 - \ln \sum_k \theta_k \tau_{ki} - \sum_j \theta_j \frac{\tau_{ij}}{\sum_k \theta_k \tau_{kj}} \right) \tag{4-175}$$

Again subscript $i$ identifies species, and $j$ and $k$ are dummy indices.

For a mixture of 20 percent propanol in water: $a_{21} = 20.4$ J/mol; $a_{12} = 2551$; $r_1 = 3.25$; $q_1 = 3.13$; $r_2 = 0.94$; $q_2 = 1.40$; $\gamma_1 = 2.721$; and $\gamma_2 = 1.140$.

The NRTL equation is the most flexible for fitting experimental data because it has three parameters per binary system, compared to two parameters for the Wilson or UNIQUAC models. For most applications, the default value of $\alpha = 0.3$ suffices for the NRTL model, making it similar to the others when limited data are available. For multicomponent systems, the subscripted form of $\alpha$ should be used to distinguish, say, $\alpha_{12} (= \alpha_{21})$ from $\alpha_{13} (= \alpha_{31})$. The Wilson parameters $\Lambda_{ij}$, NRTL parameters $G_{ij}$, and UNIQUAC parameters $\tau_{ij}$ inherit a Boltzmann-type $T$ dependence from the origins of the expressions for $G^E$, but it is only approximate. Computations of properties sensitive to this dependence (e.g., heats of mixing and liquid/liquid solubility) are in general only qualitatively correct. All parameters can be characterized from data for binary systems (in contrast to multicomponent), and this makes parameter determination for the local composition models a manageable task.

## PHASE EQUILIBRIUM DATA SOURCES

The literature on phase equilibrium measurements is vast and continually increasing. Keeping track of all the data generated throughout time and across the globe is part of the mission of the Thermodynamics Research Center (TRC) in Boulder, Colorado, a part of the Physical and Chemical Properties Division of the National Institute of Standards and Technology (NIST). The NIST TRC group has developed a website (ThermoLit [ibid]) that compiles literature sources ostensibly covering all known physical property data pertaining to one-, two-, or three-component systems. The resource compiles citations of data for vapor-liquid, liquid-liquid, and solid-fluid equilibria. The Korean Database (KDB) (http://www.cheric.org/research/kdb/hcvle/hcvle.php) provides online tabulation of some experimental data. Another database available in many university libraries is the DECHEMA database of Gmehling, Onken, and Arlt [*Vapor-Liquid Equilibrium Data Collection,* Chemistry Data Series, vol. 1, parts 1–8, DECHEMA, Frankfurt/Main, 1974–1990]. An older but still useful data collection is that of Stephens and Stephens [*Solubilities of Inorganic and Organic Compounds*, vol. 1, pts. 1 and 2, Pergamon, Oxford, England, 1960]. A database of infinite-dilution activity coefficients is included in the supporting information submitted with the article by Lazzaroni et al. [*Ind. Eng. Chem. Res.* **44**(11): 4075–4083 (2005)].

A number of other sources have compiled data from the literature into a single volume or series that may be more convenient than referring to the original literature. Comprehensive collections of phase equilibrium data (including vapor-liquid, liquid-liquid, and solid-liquid data) and infinite-dilution activity coefficients are maintained by the TRC and by DDBST, GmbH. Another database called Infotherm is available from Wiley. Other sources of thermodynamic data include the IUPAC Solubility Data Series published by Oxford University Press. Additional sources of data are discussed by Skrzecz [*Pure Appl. Chem.* (IUPAC), **69**(5): 943–950 (1997)].

**Data Reduction** Correlations for $G^E$ and the activity coefficients are based on VLE data taken at low to moderate pressures. The process of finding a suitable analytic relation for $G^E/RT$ as a function of its independent variables $T$ and $x_1$, thus producing a correlation of VLE data, is known as *data reduction*. Although in principle $G^E/RT$ is also a function of $P$, the dependence is so weak as to be usually neglected. The adjustable parameters of the models are regressed by minimizing the residuals. The maximum-likelihood method [T. F. Anderson and J. M. Prausnitz, *Ind. Eng. Chem. Proc. Res. Dev.* **17:** 552 (1978)] provides consideration that every measurement may include experimental error, but sometimes the method is difficult to reliably converge and thus a least-squares approach on bubble pressure, bubble temperature, or liquid-liquid phase behavior is typical. See also Van Ness [*J. Chem. Thermodyn.* **27:** 113–134 (1995); *Pure & Appl. Chem.* **67:** 859–872 (1995)]. Although the discussion focuses on fitting experimental data, recognize that the predictive methods discussed next may be used to generate excess Gibbs energy or activity coefficient information, and then the model parameters can be regressed against the predictions to provide a tractable multicomponent engineering process model.

## PREDICTIVE AND ADAPTIVE MODELS FOR THE EXCESS GIBBS ENERGY

**Predictive Models: UNIFAC, Solubility Parameter Models, COSMO** For the design of processes that often involve synthesis of new compounds in new combinations or at new conditions, the need to predict mixture behavior is inevitable. Some models, such as UNIFAC, represent extensive correlations with large databases and scores of parameters based on regression of group contributions. Because UNIFAC is correlated by fitting group parameters to experimental data, it might be viewed as interpolations with molecular structure as the independent variable. The group contribution approach makes UNIFAC work well computationally, but provides little intuitive insight. Other models rely on leveraging insights from the analysis of the chemical nature of the molecular structure, such as hydrogen bonding tendencies or localized electron density. These models may be less accurate when compared to a large database, but can be helpful during the conceptual stages of process or product design.

***The UNIFAC Model*** Perhaps the most widely used activity model is the UNIFAC family of group contribution methods. These methods are based on the UNIQUAC equation, such that UNIFAC stands for UNIQUAC functional-group activity coefficients, proposed by Fredenslund, Jones, and Prausnitz [*AIChE J.* **21:** 1086–1099 (1975)] and given detailed treatment by Fredenslund, Gmehling, and Rasmussen [*Vapor-Liquid Equilibrium Using UNIFAC*, Elsevier, Amsterdam, 1977], Fredenslund et al. [*Ind. Eng. Chem. Proc. Des. Dev.* **16**(4): 450–462 (1977)]; and Wittig et al. [*Ind. Eng. Chem. Res.* **42**(1): 183–188 (2003)]. Also see Jakob et al. [*Ind. Eng. Chem. Res.* **45**: 7924–7933 (2006)].

Subsequent development has led to a variety of separate correlations, each focused on specific applications, including liquid/liquid equilibria [Magnussen, Rasmussen, and Fredenslund, *Ind. Eng. Chem. Process Des. Dev.* **20:** 331–339 (1981)], solid/liquid equilibria [Anderson and Prausnitz, *Ind. Eng. Chem. Fundam.* **17:** 269–273 (1978)], solvent activities in polymer solutions [Oishi and Prausnitz, *Ind. Eng. Chem. Process Des. Dev.* **17:** 333–339 (1978)], vapor pressures of pure species [Jensen, Fredenslund, and Rasmussen, *Ind. Eng. Chem. Fundam.* **20:** 239–246 (1981)], gas solubilities [Sander, Skjold-Jørgensen, and Rasmussen, *Fluid Phase Equilibr.* **11:** 105–126 (1983)], and excess enthalpies [Dang and Tassios, *Ind. Eng. Chem. Process Des. Dev.* **25:** 22–31 (1986)].

The range of applicability of the original UNIFAC model has been greatly extended and its reliability enhanced. Its most recent revision and extension is treated by Wittig et al. (2003), wherein are cited earlier pertinent papers. Because it is based on temperature-independent parameters, its application is largely restricted to 0 to 150°C.

Two modified versions of the UNIFAC model, based on temperature-dependent parameters, have come into use. Not only do they provide a wide temperature range of applicability, but also they allow correlation of various kinds of property data, including phase equilibria, infinite-dilution activity coefficients, and excess properties. The most recent revision and extension of the modified UNIFAC (Dortmund) model is provided by Gmehling et al. [*Ind. Eng. Chem. Res.* **41:** 1678–1688 (2002)]. An extended UNIFAC model called KT-UNIFAC is described in detail by Kang et al. [*Ind. Eng. Chem. Res.* **41:** 3260–3273 (2003)], and updated [*Fluid Ph. Equilibr.* **309:** 68–75 (2011)].

The use of UNIFAC for estimating LLE is discussed by Gupte and Danner [*Ind. Eng. Chem. Res.* **26**(10): 2036–2042 (1987)] and by Hooper, Michel, and Prausnitz [*Ind. Eng. Chem. Res.* **27**(11): 2182–2187 (1988)]. Vakili-Nezhand, Modarress, and Mansoori [*Chem. Eng. Technol.* **22**(10): 847–852 (1999)] discuss its use for representing a complex stream containing a large number of components for which available LLE data are incomplete. Similar to UNIQUAC, UNIFAC calculates activity coefficients in two parts:

$$\ln \gamma_i = \ln \gamma_i^{\text{comb}} + \ln \gamma_i^{\text{res}} \tag{4-176}$$

The combinatorial part $\ln \gamma_i^{\text{comb}}$ is calculated from pure-component properties. The residual part $\ln \gamma_i^{\text{res}}$ is calculated by using binary interaction parameters for solute-solvent group pairs determined by regressing the group parameters against a large set of phase equilibrium data. Thus, the predictions are most reliable when the method is applied to monofunctional molecules similar to those used in the regression. With this approach, a molecule is treated as a mixture of various functional groups. The proximity of the groups to one another in the molecule is not taken into account.

***Solubility Parameter Models*** A number of methods based on regular solution theory are also available. Only pure-component parameters are needed to make estimates, so they may be applied when UNIFAC group-interaction parameters are not available. These methods are also sufficiently simple that

they provide intuitive guides as to what compounds might blend well or contribute to desirable solution behavior, such as increasing solution ideality.

***Scatchard-Hildebrand Theory*** Scatchard-Hildebrand solution theory defines $G^E$ in terms of

$$\frac{G^E}{RT}=\frac{U^E}{RT}=\sum x_i V_i(\delta_i-<\delta>)^2+V<<k_{mm}>> \tag{4-177}$$

$$RT\ln\gamma_i=V_i[(\delta_i-<\delta>)^2+2<k_{im}>-<<k_{mm}>>] \tag{4-178}$$

where $<\delta>=\sum\Phi_j\delta_j$, $<<k_{\mathrm{mm}}>>=\sum\Phi_i\delta_i<k_{im}>$, $<k_{im}>=\sum\Phi_j\delta_j k_{ij}$, $\Phi_i=x_iV_i/(\sum x_jV_j)$, and $k_{ij}=k_{ji}=$ a single binary parameter per binary system.

The parameter $\delta$ is known as the *Hildebrand solubility parameter* and defined in terms of pure-component properties at 25°C.

$$\delta\equiv\sqrt{\frac{\Delta U^{\mathrm{vap}}}{V^L}}\approx\sqrt{\frac{\Delta H^{\mathrm{vap}}-298.15R}{V^L}} \tag{4-179}$$

Assuming $k_{ij}=0$ for all *i, j,* the theory is predictive, but always predicts positive deviations from ideal solution behavior. This theory is generally reasonable for hydrocarbons and slightly polar substances, but not for complexing or hydrogen bonding systems. The theory can be derived from the van der Waals EOS based on the assumption of a constant packing fraction for all liquids, so its pedigree is similar in quality to that of most EOS methods. There are two guidelines that are apparent from the defining equations: (1) Systems are more nearly ideal ($G^E\approx 0$) when all the solubility parameters are equal. (2) Larger molecules tend to amplify the nonideality. The first guideline may be more familiar in the form "like dissolves like," although the mathematical model provides a more quantitative suggestion. The second guideline may sound reasonable if you are familiar with the poor mutual solubility of polymers in one another; even polyethylene and polypropylene blend poorly.

***Flory-Huggins Model*** For polymer solutions and blends, the primary workhorse continues to be the Flory-Huggins model. This model is very similar to regular solution theory, but adds a term to recognize that excess entropy ($S^E$) is significant for polymers as well as excess energy ($U^E$).

$$\ln\gamma_i=V_i[(\delta_i-<\delta>)^2+2<k_{im}>-<<k_{mm}>>]/(RT)+\left(1-\Phi_i/x_i\right)+\ln\left(\Phi_i/x_i\right) \tag{4-180}$$

***Hansen Solubility Parameters*** The Hansen solubility parameter model divides the Hildebrand solubility parameter into three parts to obtain parameters $\delta^d$, $\delta^p$, and $\delta^h$ accounting for nonpolar (dispersion), polar, and hydrogen-bonding effects [Hansen, *J. Paint Technol.* **39:** 104–117 (1967)]. An activity coefficient may be estimated by using an equation of the form

$$RT\ln\gamma_i=V_i\{(\delta_i^d-<\delta^d>)^2+0.25[(\delta_i^p-<\delta^p>)^2+(\delta_i^h-<\delta^h>)^2]\} \tag{4-181}$$

where $\delta^2=(\delta^d)^2+0.25[(\delta^p)^2+(\delta^h)^2]$ [Frank, Downey, and Gupta, *Chem. Eng. Prog.* **95**(12): 41–61 (1999)]. Equation (4-181) is equivalent to Eq. (4-178) for nonpolar mixtures with zero binary interaction parameters. The Hansen model has been used for many years to screen solvents and facilitate development of product formulations. Hansen parameters have been determined for more than 500 solvents [Hansen, *Hansen Solubility Parameters: A User's Handbook,* CRC, Boca Raton, Fla., 2000); and *CRC Handbook of Solubility Parameters and Other Cohesion Parameters,* 2d ed., ed. Barton (CRC, Boca Raton, Fla., 1991)].

***MOSCED and SPACE Models*** MOSCED (Modified Separation of Cohesive Energy Density) is another modified Scatchard-Hildebrand solution model. MOSCED utilizes two parameters to represent hydrogen bonding: one for proton donor capability (acidity) and one for proton acceptor capability (basicity) [Thomas and Eckert, *Ind. Eng. Chem. Proc. Des. Dev.* **23**(2): 194–209 (1984)]. This provides a more realistic representation of hydrogen bonding that allows more accurate modeling of a wider range of solvents, and unlike the Hansen model, MOSCED can predict negative deviations from ideal solution (activity coefficients less than 1.0). MOSCED calculates infinite-dilution activity coefficients by using

$$RT\ln\gamma_{2,1}^{\infty}=V_2\left[(\delta_2^d-\delta_1^d)^2+\frac{q_1^2q_2^2(\tau_2^T-\tau_1^T)^2}{\psi_1}+\frac{(\alpha_2^T-\alpha_1^T)(\beta_2^T-\beta_1^T)}{\xi_1}\right]+\left(1-V_2/V_1\right)^{aa}+aa\ln\left(V_2/V_1\right) \tag{4-182}$$

where $\alpha_i^T=\alpha_i\left(\frac{293}{T}\right)^{0.8}$, $\beta_i^T=\beta_i\left(\frac{293}{T}\right)^{0.8}$, $\tau_i^T=\tau_i\left(\frac{293}{T}\right)^{0.4}$

There are five adjustable parameters per molecule: the dispersion parameter $\delta^d$ originally represented as $\lambda$ by Thomas and Eckert; the induction parameter $q$; the polarity parameter $\tau$; the hydrogen-bond acidity parameter $\alpha$; and the hydrogen-bond basicity parameter $\beta$. The induction parameter $q$ often is set to a value of 0.9 or 1.0, yielding a four-parameter model. The terms *aa*, $\psi$, and $\xi$ are asymmetry factors calculated from $\alpha$, $\beta$, and $\tau$ as a function of temperature. The complete model equations and a database of parameter values for approximately 150 compounds are given by Lazzaroni et al. [*Ind. Eng. Chem. Res.* **44**(11): 4075–4083 (2005)]. An application of MOSCED in the study of liquid-liquid extraction is described by Escudero, Cabezas, and Coca [*Chem. Eng. Comm.* **173:** 135–146 (1999)]. Also see Frank et al. [*Ind. Eng. Chem. Res.* **46:** 4621–4625 (2007)]. Methods for predicting unavailable MOSCED parameters have been discussed by Gnap and Elliott, [*Fluid Phase Eq.*, in press (2018)].

Another method closely related to the MOSCED model is the SPACE model for estimating infinite-dilution activity coefficients [Hait et al., *Ind. Eng. Chem. Res.* **32**(11): 2905–2914 (1993)]. The SPACE model utilizes refractive indices and solvatochromic parameters. The solvatochromic parameters are $\alpha$ (acidity), $\beta$ (basicity), $\pi$ (polarity), and $\delta$ (polarizability). These have been measured independently of phase equilibria data using spectroscopic techniques such as NMR and UV. The number of parameters is fewer in the SPACE model, in principle, but there are several generalized correlations required to implement the method. The more recent paper by Lazzaroni et al. offers the simplest and most reliable method between SPACE and MOSCED.

Table 4-1 shows typical values for MOSCED parameters over a range of compounds. In the absence of hydrogen bonding, as in the case of acetone + *n*-octane, mixing follows the formula based on differences in $\delta^d$ and $\tau$; positive deviations are predicted. The acidity and basicity provide the strongest indication of solution nonideality. When both $\alpha$ and $\beta$ are significant for a given compound, mixing with a compound that has small $\alpha$ and $\beta$ leads to large positive deviations from ideality, as in the case of phenol + *n*-decane. An azeotrope or liquid-liquid equilibrium should be suspected for such a system. When one compound is relatively acidic and the other relatively basic, as for phenol + pyridine, negative (exothermic) deviations from ideality should be expected. Finally, when both compounds have similar acidity and basicity, the influences of hydrogen bonding may cancel and the mixture behavior returns to being ideal, as in the case of phenol + benzyl alcohol.

**TABLE 4-1 Sampling of MOSCED Parameters**

| | $\rho_{298}$ | $\delta$(J/cm$^3$)$^{1/2}$ | $\alpha$ | $\beta$ | $\delta^d$ | $\tau$ |
|---|---|---|---|---|---|---|
| Acetic Acid | 1.04 | 19 | 24.03 | 7.5 | 14.96 | 3.23 |
| Acetone | 0.79 | 19.64 | 0 | 11.14 | 13.71 | 8.3 |
| Aniline | 1.02 | 24.12 | 6.51 | 6.34 | 16.51 | 9.41 |
| Benzene | 0.87 | 18.73 | 0.63 | 2.24 | 16.71 | 3.95 |
| Benzyl Alcohol | 1.04 | 24.7 | 15.01 | 6.69 | 16.56 | 5.03 |
| Chloroform | 1.48 | 18.92 | 5.8 | 0.12 | 15.61 | 4.5 |
| *n*-Decane | 0.73 | 15.7 | 0 | 0 | 15.7 | 0 |
| Ethanol | 0.79 | 26.13 | 12.58 | 13.29 | 14.37 | 2.53 |
| Iso-octane | 0.7 | 14.11 | 0 | 0 | 14.11 | 0 |
| Methanol | 0.79 | 29.59 | 17.43 | 14.49 | 14.43 | 3.77 |
| MTBE | 0.74 | 15.17 | 0 | 7.4 | 15.17 | 2.48 |
| *n*-Octane | 0.7 | 15.5 | 0 | 0 | 15.5 | 0 |
| Phenol | 1.06 | 24.63 | 25.14 | 5.35 | 16.66 | 4.5 |
| Pyridine | 0.98 | 21.56 | 1.61 | 14.93 | 16.39 | 6.13 |
| Water | 1 | 47.86 | 52.78 | 15.86 | 10.58 | 10.48 |
| *p*-xylene | 0.86 | 17.9 | 0.27 | 1.87 | 16.06 | 2.7 |

In general, perusing Table 4-1 shows that most alcohols exhibit balanced acidity and basicity, although the magnitudes of $\alpha$ and $\beta$ decrease as the molecular volume increases. Ketones, ethers, aldehydes, amines, and esters tend to be relatively basic. Distinctly acidic behavior is less common, except for aromatic alcohols and, of course, carboxylic acids. These elementary insights can go a long way toward making solution behavior seem less mysterious. We revisit these insights when we consider the guidelines of phase diagrams and Robbins' table.

***COSMO Models: COSMO-RS and COSMO-SAC*** The thermodynamic methods described above glean information from available data to make estimates for other systems. As an alternative approach, quantum chemistry calculations and molecular simulation methods are finding greater use in engineering applications [Gupta and Olson, *Ind. Eng. Chem. Res.* **42**(25): 6359–6374 (2003); and Chen and Mathias, *AIChE J.* **48**(2): 194–200 (2002)]. These methods minimize the need for data; however, the computational effort and specialized expertise required to use them are generally higher, and the accuracy of the

results may not be known. An important method gaining increasing application in the chemical industry is the conductor-like screening model (COSMO) introduced by Klamt and colleagues [Klamt, *J. Phys. Chem.* **99:** 2224 (1995); Klamt and Eckert, *Fluid Phase Equilibr.* **172:** 43–72 (2000); Eckert and Klamt, *AIChE J.* **48**(2): 369–385 (2002); and Klamt, *From Quantum Chemistry to Fluid Phase Thermodynamics and Drug Design,* Elsevier, Amsterdam, 2005]. Also see Grensemann and Gmehling, *Ind. Eng. Chem. Res.* **44**(5): 1610–1624 (2005). This method utilizes computational quantum mechanics to calculate a two-dimensional electron density profile to characterize a given molecule. This profile is then used to estimate phase equilibrium through application of statistical mechanics and solvation theory. The Klamt model is called COSMO-RS ( for realistic solvation). A similar model is COSMO-SAC ( for segment activity coefficient) published by Lin and Sandler [*Ind. Eng. Chem. Res.* **41**(5): 899–913, 2332 (2002)]. Databases of electron density profiles (sigma profiles) are available from a number of vendors and universities. A sigma-profile database of more than 1000 molecules is available from the Virginia Polytechnic Institute and State University [Mullins et al., *Ind. Eng. Chem. Res.* **45**(12): 4389–4415 (2006)]. An application of COSMOS-RS to predict liquid-liquid equilibria is discussed by Banerjee et al. [*Ind. Eng. Chem. Res.* **46**(4): 1292–1304 (2007)].

**Adaptive Models LSER, NRTL-SAC** When data are available for a homologous series of compounds, but not the specific compound of interest, linear solvation energy relationships (LSERs) may be useful. A method developed by Meyer and Maurer [*Ind. Eng. Chem. Res.* **34**(1): 373–381 (1995)] uses the LSER model [Taft et al., *Nature* **313:** 384 (1985); and Taft et al., *J. Pharma Sci.* **74:** 807–814 (1985)] to estimate infinite-dilution partition ratios for solutes distributed between water and an organic solvent. The model uses 36 generalized parameters and 4 solvatochromic parameters to characterize a given solute. Also see Abraham, Ibrahim, and Zissimos, *J. Chromatography* **1037:** 29–47 (2004).

**Other Estimation Methods** Another method for estimating activity coefficients is described by Chen and Song [*Ind. Eng. Chem. Res.* **43**(26): 8354–8362 (2004); **44**(23): 8909–8921 (2005)]. This method involves regression of a small data set in a manner similar to the way the Hansen and MOSCED models typically are used. The model is based on a modified NRTL framework called NRTL-SAC ( for segment activity coefficient) that utilizes only pure-component parameters to represent polar, hydrophobic, and hydrophilic segments of a molecule. An electrolyte parameter may be added to characterize ion-ion and ion-molecule interactions attributed to ionized segments of species in solution. The resulting model may be used to estimate activity coefficients and related properties for nonionic organics plus electrolytes in aqueous and nonaqueous solvents.

Another approach involves use of molecular simulation or electron density calculations to predict values of parameters for phase equilibrium models. An example involves prediction of MOSCED parameters [R. Ley, G. Fuerst, B. Redeker, and A. Paluch, *Ind. Eng. Chem. Res.* **55**(18): 5415–5430 (2016); J. Phifer, K. Soloman, K. Young, and A. Paluch, *AIChE J.* **63:** 781–791 (2017)]. This approach combines molecular modeling and phase equilibrium theory to obtain a predictive tool well suited to early-stage process development.

## MODEL SELECTION

Model selection can seem overwhelming due to the large number of possible models. Use of correlative methods fitted to experimental data is preferred over predictive methods, and sometimes a local fit of parameters is necessary [P. M. Mathias, *J. Chem. Eng. Data.* **61:** 4077–4084 (2016)]. Predictive methods should be used cautiously when the compounds of interest differ from those used in the model development or when multifunctional molecules are present.

For subcritical systems (say, $P < 15$ bar), an activity model is likely to suffice. The NRTL model has the advantage of a third parameter when needed, so try it first with $\alpha = 0.3$, then adjust $\alpha$ if necessary. If the comparison indicates liquid-liquid equilibrium where there is none, try the Wilson model. LLE is indicated by a minimax in the predicted *y-x* curve. If a substantial gap exists in the experimental data along the *x* axis, it may be that the system exhibits LLE.

Careful model validation against experiment is especially critical for the heavy and light key components in distillation. Multiple columns would have multiple keys so each pair would need to be checked. For the components of secondary importance, experimental data should be sought but predictive methods (such as UNIFAC) can be applied if necessary. Generally, different model parameters are needed for VLE and LLE, even with the same model. If a different model or parameter set is best for different unit operations, customize each operation. If multicomponent data are available, a *y-x* comparison to experiment is possible by applying a pseudocomponent basis, $y' = y_L/(y_L + y_H)$, for example. Of course, the experimental data should be as close to process conditions as possible, but data within 50°C of process conditions should suffice. Processes involving components with significant association in the vapor phase (e.g., carboxylic acids) should include an association model such as that of Hayden-O'Connell.

For processes with fluids near a critical point or with retrograde condensation, it is advisable to try an EOS method. The General References include discussions of phase diagrams in the critical region [e.g., Elliott and Lira, chapter 16 (2012)]. It may be necessary to compare several models in these cases. For predictions, the predictive SRK method provides a reasonable start [Horstmann et al., *Fluid Phase Equilibr.* **167:** 173–186 (2000)]. For correlation, the modified Huron-Vidal method prevails in most comparisons. If systems involve heavy components or polymers in important roles, the PC-SAFT model should be considered. The PC-SAFT model shows promise as a basis for both prediction and correlation, but it has not been fully implemented in all process simulators. After EOS methods are tried, activity models should be considered also as long as one of the key components is not supercritical. The model that agrees best with experiment is preferred.

## PRELIMINARY ESTIMATES

It may be advisable to consider some relatively quick guidelines before delving deeply into computer calculations. Often, considering the kinds of phase behavior to be encountered before seeing the computational output may facilitate a critical evaluation of the output. In other cases, applications of interest may require formulations that involve multiple components designed to achieve a certain process objective such as moderating the solution nonideality for an extractive distillation or finding a liquid solvent that extracts the solute of interest from a diluent while maintaining minimal mutual solubility between solvent and diluent. A purely computational approach might involve many random trials and errors, while phenomenological consideration of a model such as MOSCED could help to guide the search. Two useful approaches are outlined briefly below.

**Robbins' Table** The interactions of polar and hydrogen bonding forces evident in the MOSCED, Hansen, and COSMO models lead to intuitive insights about how combinations of chemicals may behave in solution. This insight can be helpful when choosing an entrainer for an azeotropic system or a solvent for liquid-liquid extraction, for example. A well-known guide is Robbins' table (Table 4-2) of solute-solvent interactions [*Chem. Eng. Prog.* **76**(10): 58–61 (1980).] This table indicates whether interactions between compounds are likely to yield positive, negative, or near-zero deviations from ideal solution behavior. Similar tables for anticipating solvent-solute interactions are often cited in discussions of distillation and liquid extraction. These rely largely on classifications of hydrogen bonding and polarity that are similar to the intent to those of Robbins' table, with similar results.

**TABLE 4-2 Robbins' Table (Modified by Gnap and Elliott) of Solute–Solvent Interactions***

| | $\alpha'(J)^{1/2}$ | $\beta'(J)^{1/2}$ | Class | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |

*Detailed class descriptions are given in the text.

The listings of acidity and basicity may be viewed in terms of average acidity or basicity as characterized by the MOSCED model. The entries in the classic Robbins' table can be predicted about 70 percent of the time with the formula

$$\Delta^{is} = \frac{(\alpha_2' - \alpha_1')(\beta_2' - \beta_1')}{(\alpha_2' + \alpha_1')(\beta_2' + \beta_1')} \tag{4-183}$$

where $\alpha_i'$ and $\beta_i'$ are the generalized values. When $\Delta^{is} < -0.2$, a negative deviation is indicated. When $\Delta^{is} > 0.4$, a positive deviation is indicated. For $-0.2 < \Delta^{is} < 0.4$, relatively ideal solution behavior can be expected. The primary source of discrepancies between Eq. (4-183) and Robbins' table involves differences in the assessment of polarity. For example, mixtures of esters with paraffins normally give positive deviations from ideality, but calculated $\Delta^{is}$ values can be close to zero. This discrepancy might be anticipated by including the MOSCED term for polarity in the assessment, but this level of detail would undermine the simplicity of Robbins' table.

In this modified version, the classifications of phenols, acids, and halogenated acids have been adjusted somewhat to take polarity effects into account. The detailed groupings for each classification are as follows: (1) Acids, phenols, active H on multihalogen paraffin; (2) thiols; (3) alcohol,

water; (4) ketones, tertiary amide, sulfone, phosphine; (5) tertiary amine; (6) secondary amine; (7) primary amine, primary amide, $NH_3$; (8) ether, oxide, sulfoxide; (9) ester, aldehyde, carbonate, phosphate, nitrate, nitrite, nitrile, intramolecular H bonding (e.g., *o*-nitrophenol); (10) aromatic, olefin, halogenated aromatic, multihalogen paraffin without active H, and monohalogen paraffin; (11) paraffin and carbon disulfide.

***Example 4-10 Entrainer Selection for Extractive Distillation*** A common problem in gasohol production is overcoming the ethanol + water azeotrope. Extractive distillation involves the addition of a relatively nonvolatile entrainer that is miscible in both components. interacts favorably with the less volatile component (water in this case), and moderates the solution nonideality. Candidates for the entrainer are glycerol triacetate, monoethanolamine, and ethylene glycol. Which candidate is most promising from the perspective of Robbins' table?

*Solution* Glycerol triacetate is an ester with a boiling point near 258°C, monoethanolamine is an alcohol/primary amine with boiling point near 170°C, and ethylene glycol is a diol with a boiling point of 198°C (chemspider.com is convenient for this kind of search). Although the acid/base combination seems favorable for the triacetate, Robbins' table indicates a positive deviation from ideality. The glycol is simply another alcohol, so it indicates zero deviation. The ethanolamine is similar to glycol except that one hydroxyl has been replaced by a primary amine. The primary amine indicates a negative deviation from ideality, suggesting that it should provide more powerful suppression of the water activity, requiring less entrainer. Therefore, monoethanolamine would be recommended by Robbins' perspective. Other considerations such as cost, toxicity, reactivity (the acetate would likely hydrolyze and monoethanolamine may react with trace impurities), or ease of entrainer regeneration must also be considered.

**Phase Diagrams** Either solutions can be ideal, or they can exhibit positive ($\gamma >$ unity) or negative ($\gamma <$ unity) deviations from ideality. Ideal solutions cannot exhibit liquid-liquid equilibrium (LLE) or azeotropes. Negative deviations from ideality cannot result in LLE, but they can result in azeotrope formation. Positive deviations from ideality can result in azeotropes and LLE if the activity coefficients are large enough. For a binary solution, if the geometric mean of the infinite-dilution activity coefficients exceeds 10, the prospect of LLE should be checked. In the case of vapor-liquid equilibria (VLE), the relative volatility is important to consider.

$$\alpha_{ij} \equiv \frac{K_i}{K_j} = \frac{\gamma_i P_i^{\text{sat}}}{\gamma_j P_j^{\text{sat}}} \tag{4-184}$$

where $K_i = y_i/x_i$ is the ratio of vapor mole fraction to liquid mole fraction and the order of $i$ and $j$ is chosen such that $P_i^{\text{sat}} > P_j^{\text{sat}}$, indicating that $\alpha_{ij} > 1$ for an ideal solution. If $\alpha_{ij} < 1$ for some range of compositions, an azeotrope occurs. Azeotropes are important because distillation fails when the vapor and liquid phases have the same composition. Checking the relative volatility of key components at both top and bottom of the column is recommended, deliberately verifying whether it crosses unity.

These cases can be illustrated by Fig. 4-2. *T-xy* diagrams have two advantages: (1) the onset of LLE is easier to show than in a *P-xy* diagram and (2) most

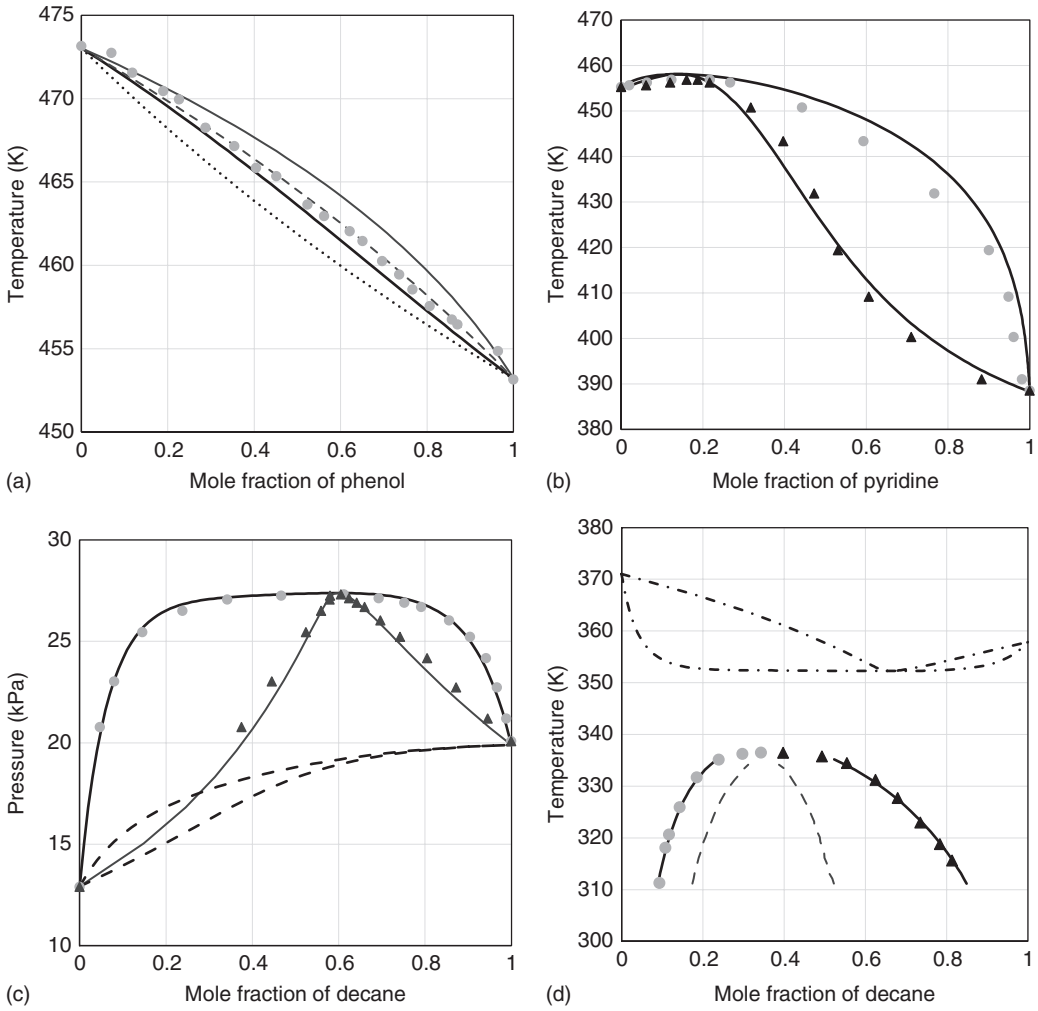

**FIG. 4-2** Phase diagrams fit using the NRTL model. (*a*) *T-xy* for phenol(1) + *p*-cresol(2) at 96.4 kPa. $b_{12} = 1567.2$ J/mol, $b_{21} = -2010.3$, $\alpha = 0.3$. Data of Selvam et al. [*Fluid Phase Equilibr.* **78:** 261–267 (1992). $\gamma_1^\infty$(NRTL) = 0.85, $\gamma_2^\infty = 0.81$. Dotted lines show the ideal solution model. (*b*) *T-xy* for pyridine(1) + phenol(2) at 101.32 kPa. $b_{12} = -7235.8$ J/mol, $b_{21} = 1886.5$, $\alpha = 0.3$. Data of F. A. Assal [*Bull. Acad. Pol. Sci. Ser. Sci. Chim.* **14:** 603 (1966)]. $\gamma_1^\infty$(NRTL) = 0.055, $\gamma_2^\infty = 0.17$. (*c*) *P-xy* for *n*-decane(1) + phenol(2) at 119.8°C. Solid lines use $b_{12} = 4259.6$ J/mol, $b_{21} = 5729.5$, $\alpha = 0.43$, $\gamma_1^\infty$(NRTL) = 12.2, $\gamma_2^\infty = 8.4$. Dotted lines use parameters from figure (*d*), $\gamma_1^\infty$(NRTL) = 2.5, $\gamma_2^\infty = 1.5$. (*d*) *T-xy* for *n*-decane(1) + phenol(2) at 5 kPa. Solid lines use $b_{12} = -71.382T$(K) + 26038 J/mol, $b_{21} = 1.9217T$(K) + 4704.8, $\alpha = 0.3$. Dotted lines using parameters from (*c*). Figures (*c*) and (*d*) use data of Gmehling [*J. Chem. Eng. Data* **27:** 371 (1982)].

phase separation processes are conducted at nearly constant pressure. Figure 4-2*a* shows the case of a nearly ideal solution. Figure 4-2*b* shows a maximum boiling azeotrope. When phenol mixes with *p*-cresol, the solution is nearly ideal, but when it mixes with pyridine, an exothermic acid-base interaction ensues. Since the vapor pressures of phenol and pyridine are similar, the ratio of activity coefficients overwhelms the ratio of vapor pressures in the relative volatility, and a maximum boiling azeotrope results. A similar phenomenon occurs for *n*-decane + phenol, but with large positive deviations from ideality overwhelming the vapor pressure ratio and causing a minimum boiling azeotrope, as shown in Fig. 4-2*c* and *d*. The rationale for associating the system with a minimum boiling azeotrope is most evident in Fig. 4-2*d*, where it is evident that *boiling* refers to the bubble temperature, not bubble pressure. Figure 4-2*c* shows that the *P-xy* diagram is the flipped top-to-bottom image of the *T-xy* diagram for the same system. Also evident in Fig. 4-2*d* is the onset of LLE at temperatures below the bubble point. At higher pressures, the bubble curve would increase to higher temperatures and the LLE would be relatively unaffected. In some mixtures, where the nonideality is larger than for the system illustrated, the VLE curve may intersect with the LLE curve, resulting in VLLE. Finally, Fig. 4-2*c* and *d* illustrates a challenge in representing VLE and LLE simultaneously with universal parameters. The parameters fitted to VLE in Fig. 4-2*c* give a poor representation of LLE in Fig. 4-2*d*. Similarly, the parameters fitted to LLE in Fig. 4-2*d* give a poor representation of VLE in Fig. 4-2*c*. Therefore, the "optimal" assessment depends on the job at hand.

## VAPOR/LIQUID EQUILIBRIUM

Vapor/liquid equilibrium (VLE) relationships (as well as other interphase equilibrium relationships) are needed in the solution of many engineering problems. The general VLE problem treats a multicomponent system of $N$ constituent species for which the independent variables are $T$, $P$, $N-1$ liquid-phase mole fractions and $N-1$ vapor-phase mole fractions. (Note that $\sum_i x_i = 1$ and $\sum_i y_i = 1$, where $x_i$ and $y_i$ represent liquid and vapor mole fractions, respectively.) Thus there are $2N$ independent variables, and application of the phase rule shows that exactly $N$ of these variables must be fixed to establish the intensive state of the system. This means that once $N$ variables have been specified, the remaining $N$ variables can be determined by simultaneous solution of the $N$ equilibrium relations [Eq. (4-127)]. In practice, either $T$ or $P$ *and* either the liquid-phase or vapor-phase composition are specified, thus fixing $1 + N - 1 = N$ independent variables.

***K* Values, VLE, and Flash Calculations** A measure of the distribution of a chemical species between liquid and vapor phases is the $K$ value, defined as the *equilibrium ratio*:

$$K_i \equiv \frac{y_i}{x_i} \tag{4-185}$$

It has no thermodynamic content, but may make for computational convenience through elimination of one set of mole fractions in favor of the other. It does characterize "lightness" of a constituent species. A "light" species, with $K > 1$, tends to concentrate in the vapor phase, whereas a "heavy" species, with $K < 1$, tends to concentrate in the liquid phase. In practice, at least one $K_i \geq 1$, and at least one $K_i \leq 1$.

The defining equation for $K$ can be rearranged as $y_i = K_i x_i$. The sum $\sum_i y_i = 1$ then yields

$$\sum_i K_i x_i = 1 \tag{4-186}$$

With the alternative rearrangement $x_i = y_i/K_i$, the sum $\sum_i x_i = 1$ yields

$$\sum_i \frac{y_i}{K_i} = 1 \tag{4-187}$$

Thus for bubble point calculations, where the $x_i$ are known, the problem is to find the set of $K$ values that satisfies Eq. (4-186), whereas for dew point calculations, where the $y_i$ are known, the problem is to find the set of $K$ values that satisfies Eq. (4-187).

The *flash calculation* is a very common application of VLE. Considered here is the *P, T* flash, in which are calculated the quantities and compositions of the vapor and liquid phases in equilibrium at known $T$, $P$, and *overall* composition. This problem is determinate on the basis of Duhem's theorem: *For any closed system formed initially from given masses of prescribed chemical species, the equilibrium state is completely determined when any two independent variables are fixed.* The independent variables are here $T$ and $P$, and systems are formed from given masses of nonreacting chemical species.

For $F$ moles fed of a system with *overall* composition represented by the set of mole fractions $\{z_i\}$, let $L$ represent the moles of the system that are liquid (mole fractions $\{x_i\}$) and let $V$ represent the moles that are vapor (mole fractions $\{y_i\}$). The material balance equations are

$$L + V = F \qquad \text{and} \qquad z_i F = x_i L + y_i V \qquad i = 1, 2, \ldots, N \tag{4-188}$$

Rearranging for $x_i$ and $y_i$ yields

$$x_i = z_i/(1+(V/F)(K_i-1)), \quad y_i = z_i K_i/(1+(V/F)(K_i-1)) \tag{4-189}$$

Taking the difference in the sums results in the Rachford-Rice flash method [Elliott and Lira (2012, Sec. 10.3)]

$$\sum_i \frac{z_i(1-K_i)}{1+(V/F)(K_i-1)} = 0 \tag{4-190}$$

The initial step in solving a $P$, $T$ flash problem is to find the value of $V/F$ which satisfies Eq. (4-190), and then mole fractions are determined by Eq. (4-189).

**Gamma/Phi Approach** For many VLE systems of interest, the pressure is low enough that evaluation of $\hat{\phi}_i$ is usually by Eq. (4-157), based on the two-term virial equation of state. Liquid-phase behavior, on the other hand, uses activity coefficients $\gamma_i$, based on Eq. (4-146) applied to an expression for $G^E/RT$, as described in the section Models for the Excess Gibbs Energy.

Equation (4-135) may now be written as

$$y_i P \Phi_i = x_i \gamma_i P_i^{\text{sat}} \qquad i = 1,2,\ldots,N \tag{4-191}$$

where

$$\Phi_i = \frac{\hat{\phi}_i}{\phi_i^{\text{sat}}} \exp\left[\frac{-V_i^L(P-P_i^{\text{sat}})}{RT}\right] \tag{4-192}$$

If evaluation of $\phi_i^{\text{sat}}$ is based on Eq. (4-70) evaluated at $P^{\text{sat}}$, and $\hat{\phi}_i$ by Eq. (4-157), this reduces to

$$\Phi_i = \exp\left[\frac{P(2\sum_k y_k B_{ki} - B) - P_i^{\text{sat}} B_{ii} - V_i^l (P - P_i^{\text{sat}})}{RT}\right] \tag{4-193}$$

The $N$ equations represented by Eq. (4-191) in conjunction with Eq. (4-193) may be solved for $N$ unknown phase equilibrium variables. For a multicomponent system the calculation is best done by computer.

**Raoult's Law** When Eq. (4-191) is applied to VLE for which the vapor phase is an ideal gas and the liquid phase is an ideal solution, it reduces to a very simple expression. For ideal gases, fugacity coefficients $\hat{\phi}_i$ and $\phi_i^{\text{sat}}$ are unity, and the right side of Eq. (4-192) reduces to the Poynting factor. For the systems of interest here, this factor is always very close to unity, and for practical purposes $\Phi_i = 1$. For ideal solutions, the activity coefficients $\gamma_i$ are also unity, and Eq. (4-191) reduces to

$$y_i P = x_i P_i^{\text{sat}}, \qquad K_i = P_i^{\text{sat}}/P \qquad i = 1, 2, \ldots, N \tag{4-194}$$

an equation which expresses *Raoult's law*. It is the simplest possible equation for VLE and as such fails to provide a realistic representation of real behavior for most systems. Nevertheless, it is useful as a standard of comparison.

**Modified Raoult's Law** Of the qualifications that lead to Raoult's law, the one least often reasonable is the supposition of solution ideality for the liquid phase. Real solution behavior is reflected by values of activity coefficients that differ from unity. When $\gamma_i$ of Eq. (4-191) is retained in the equilibrium equation, the result is the *modified Raoult's law*:

$$y_i P = x_i \gamma_i P_i^{\text{sat}}, \quad K_i = \gamma_i P_i^{\text{sat}}/P \quad i = 1, 2, \ldots, N \tag{4-195}$$

This equation is often adequate when applied to systems at low to moderate pressures and is therefore widely used. Bubble point and dew point calculations are only a bit more complex than the same calculations with Raoult's law.

For a bubble calculation, because $\sum_i y_i = 1$, Eq. (4-195) may be summed over all species to yield

$$P = \sum_i x_i \gamma_i P_i^{\text{sat}} \tag{4-196}$$

As discussed in relation to Eq. (4-139), the value of $\gamma_i$ serves as a correction factor for the solute mole fraction concentration $x_i$ to better account for the solute's true chemical potential–driven activity which determines phase equilibrium behavior and reactivity, where activity is given by $a_i = \gamma_i x_i$.

For dew calculation, Eq. (4-195) may be solved for $x_i$, in which case summing over all species yields

$$P = \frac{1}{\sum_i y_i / \gamma_i P_i^{\text{sat}}} \tag{4-197}$$

The application of this equation requires iteration because the values of $\gamma_i$ cannot be determined without an estimate of $\{x_i\}$.

***Example 4-11 Bubble, Dew, Azeotrope, and Flash Calculations*** As indicated by Example 4-8, a binary mixture in vapor/liquid equilibrium has 2 degrees of freedom. Thus of the four phase rule variables $T$, $P$, $x_1$, and $y_1$, two must be fixed to allow calculation of the other two, regardless of the formulation of the equilibrium equations. Modified Raoult's law [Eq. (4-195)] may therefore be applied to the calculation of any pair of phase rule variables, given the other two.

The necessary vapor pressures and activity coefficients are supplied by data correlations. For the system acetone(1)/*n*-hexane(2), vapor pressures are given by Eq. (4-15), with parameters for $P_i^{\text{sat}}$ (kPa) and $T$ (K),

| $i$ | $A_i$ | $B_i$ | $C_i$ |
|---|---|---|---|
| 1 | 14.3145 | 2756.22 | −45.090 |
| 2 | 13.8193 | 2696.04 | −48.833 |

Activity coefficients are calculated by Eq. (4-163), the Wilson equation, here adapted for a binary system in Eqs. (A) and (B) which will be referenced below:

$$\ln \gamma_1 = -\ln(x_1 + x_2\Lambda_{12}) + x_2\lambda \tag{A}$$

$$\ln \gamma_2 = -\ln(x_2 + x_1\Lambda_{21}) - x_1\lambda \tag{B}$$

where $$\lambda \equiv \frac{\Lambda_{12}}{x_1 + x_2\Lambda_{12}} - \frac{\Lambda_{21}}{x_2 + x_1\Lambda_{21}}$$

By Eq. (4-164) $$\Lambda_{ij} = \frac{V_j}{V_i}\exp\frac{-a_{ij}}{RT} \qquad i \neq j$$

with parameters [Gmehling et al., *Vapor-Liquid Data Collection*, Chemistry Data Series, vol. 1, part 3, DECHEMA, Frankfurt/Main, 1983]

| $a_{12}$ | $a_{21}$ | $V_1$ | $V_2$ |
|---|---|---|---|
| cal mol$^{-1}$ | cal mol$^{-1}$ | cm$^3$ mol$^{-1}$ | cm$^3$ mol$^{-1}$ |
| 985.05 | 453.57 | 74.05 | 131.61 |

When $T$ and $x_1$ are given, the calculation is direct, with final values for vapor pressures by Eq. (4-15) and activity coefficients from Eqs. (A) and (B) above. In all other cases either $T$ or $x_1$ or both are initially unknown, and calculations require iteration. For each part of this example, results are tabulated in the table at the end where given values are in italic; calculated values are in boldface.

*a. BUBL P* calculation: Find $y_1$ and $P$, given $x_1 = 0.40$ and $T = 325.15$ K (52°C). Noting that $T$ and $x_1$ are given and following the procedure above yields the values listed in the summary table in the following column. Equations (4-196) and (4-195) then become

$$P = x_i\gamma_i P_1^{\text{sat}} + x_2\gamma_2 P_2^{\text{sat}} = (0.40)(1.8053)(87.616) + (0.60)(1.2869)(58.105)$$

$$= 108.134 \text{ kPa}$$

$$y_i = \frac{x_i\gamma_i P_1^{\text{sat}}}{P} = \frac{(0.40)(1.8053)(87.616)}{108.134} = 0.5851$$

*b. DEW P* calculation: Find $x_1$ and $P$, for $y_1 = 0.4$ and $T = 325.15$ K (52°C). With $x_1$ an unknown, the activity coefficients cannot be immediately calculated. However, an iteration scheme based on Eq. (4-197) is easily developed. Starting values result from setting each $\gamma_i = 1$ and refining by using Eqs. (A) and (B) after finding $\{x\}$; results of successive substitution of $\{x\}$ to refine $\gamma_i$ values are listed in the accompanying table.

*c. BUBL T* calculation: Find $y_1$ and $T$, given $x_1 = 0.32$ and $P = 80$ kPa. With $T$ unknown, neither the vapor pressures nor the activity coefficients can be initially calculated. An iteration scheme based on Eq. (4-196) matches $P$ and results in values listed in the accompanying table.

*d. DEW T* calculation: Find $x_1$ and $T$ for $y_1 = 0.60$ and $P = 101.33$ kPa. Start with $\gamma_i = 1$. Iterate on $\sum y_i P/(\gamma_i P_i^{\text{sat}}) = 1$. Find $x_i = y_i P/(\gamma_i P_i^{\text{sat}})$ and new values of $\gamma_i$ using Eqs. (A) and (B). Iterate. Results are listed in the accompanying table.

*e., f.* Azeotrope calculations: Find the azeotrope composition and (*e*) $P$ at 46°C and (*f*) $T$ at 101.33 kPa. As noted in Example 4-8, only a single degree of freedom exists for this special case. The most sensitive quantity for identifying the azeotropic state is the relative volatility defined in Eq. (4-184). Because $y_i = x_i$ for the azeotropic state, $\alpha_{12} = 1$. Substitution for the $K$ ratios by Eq. (4-195) provides an equation for calculation of $\alpha_{12} = \gamma_1 P_1^{\text{sat}}/(\gamma_2 P_2^{\text{sat}})$. Because $\alpha_{12}$ is a monotonic function of $x_1$, the test of whether an azeotrope exists at a given $T$ or $P$ is provided by values of $\alpha_{12}$ in the limits of $x_1 = 0$ and $x_1 = 1$. If *both* values are either >1 or <1, no azeotrope exists. But if one value is <1 and the other >1, an azeotrope necessarily exists at the given $T$ or $P$. Given $T$, the azeotropic composition and pressure is found by seeking the value of $x$ that makes $\alpha_{12} = 1$ using bubble $P$ calculations at each guess. At 46°C, the limiting values of $\alpha_{12}$ are 8.289 at $x_1 = 0$ and 0.223 at $x_1 = 1$. Similarly, given $P$, one finds the azeotropic composition and temperature, using bubble $T$ calculations at each guess. The results are tabulated below.

*g.* Isothermal flash: $z_1 = 0.4000$ at $T = 325.15$ K and $P = 101.33$ kPa. Determine $V/F$, $x_1$, and $y_1$. Looking at the summary table for parts (*a*) and (*b*) reveals that the pressure is between the bubble and dew conditions; thus there will be two phases. For a binary system, a trial and error method can be formulated by starting with $x$ and using Eq. (4-189) to find $V/F$ and checking if the $y$ values sum to 1. However, this method cannot be generalized to a multicomponent system. A more general method is to start with Raoult's law and use Eq. (4-190) to find $V/F$, generate $\{x\}$ from Eq. (4-189), then use modified Raoult's law (4-195) for $K_i$ and loop back to Eq. (4-190), repeating the loop until it converges. The converged value is $V/F = 0.578$.

| | $T$ (K) | $P_1^{\text{sat}}$ (kPa) | $P_2^{\text{sat}}$ (kPa) | $\gamma_1$ | $\gamma_2$ | $x_1$ | $y_1$ | $P$ (kPa) |
|---|---|---|---|---|---|---|---|---|
| *a.* | *325.15* | 87.616 | 58.105 | 1.8053 | 1.2869 | *0.4000* | **0.5851** | **108.134** |

**Equation-of-State Approach** The gamma/phi method is generally applicable to systems away from critical points. Equations of state can treat near-critical conditions and the transition to supercritical conditions seamlessly. Of course, there is a cost in terms of robustness of convergence and computational complexity. By Eq. (4-134),

$$x_i\hat{\phi}_i^l = y_i\hat{\phi}_i^v \Rightarrow K_i = \hat{\phi}_i^l/\hat{\phi}_i^v, \quad i = 1, 2, \ldots, N \tag{4-198}$$

This introduces compositions $x_i$ and $y_i$ into the equilibrium equations, but neither is explicit, because the $\hat{\phi}_i$ are functions not only of $T$ and $P$, but of composition. Thus, Eq. (4-198) represents $N$ complex relationships connecting $T$, $P$, $\{x_i\}$, and $\{y_i\}$ where the fugacity coefficients are given by an equation of state, for example Eq. (4-158).

For mixtures the presumption is that the equation of state has exactly the same form as when written for pure species. Liquid and vapor mixtures in equilibrium in general have different compositions, and thus the $B$ and $A(T)$ parameters differ for each phase, resulting in a different isotherm for each phase. The $PV$ isotherms generated by an equation of state for these different compositions are represented in Fig. 4-3 by two similar lines: the solid line for the liquid-phase composition and the dashed line for the vapor-phase composition. They are displaced from each other because the equation-of-state parameters are different for the two compositions.

Each isotherm in the illustration includes a liquid root segment (steep segment to the left of the minimum) and vapor root segment (segment to the right of the maximum). Each liquid segment contains a bubble point (saturated liquid), and each right segment contains a dew point (saturated vapor). Because these points for a given line are for the same composition, they do not represent phases in equilibrium and do not lie at the same pressure. Shown in the figure is a bubble point $B$ on the solid line and a dew point $D$ on the dashed line. Because they lie at the same $P$, they represent phases in equilibrium, and the lines are characterized by the liquid and vapor compositions.

As a consequence of the isotherm shape depending on composition, a particular iteration may result in a trial composition such that the root pertaining to the phase of interest is imaginary. For example, consider a

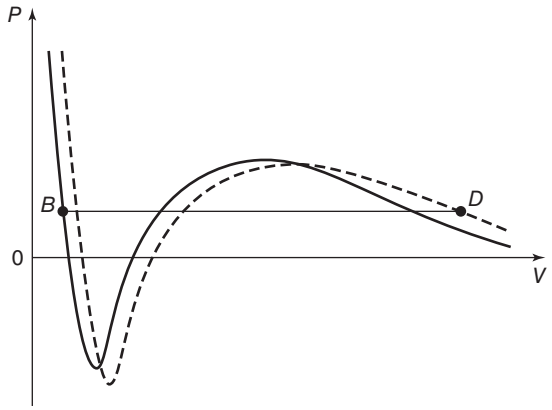

**FIG. 4-3** Two *PV* isotherms at the same *T* for mixtures. The solid line is for a liquid-phase composition; the dashed line is for a vapor-phase composition. Point *B* represents a bubble point with the liquid-phase composition; point *D* represents a dew point with the vapor-phase composition. When these points lie at the same *P* (as shown), they represent phases in equilibrium [Smith, Van Ness, and Abbott, *Introduction to Chemical Engineering Thermodynamics*, 7th ed., McGraw-Hill, New York, 2005, p. 560].

mixture of methane and nitrogen at 150 K and 10 bar. The nitrogen is above its critical temperature, so the pressure vs. density can have only one real root, while pure methane at these conditions has three roots, with a local minimum between the liquid root and the middle root. As the composition varies, the pressure vs. density evolves such that the liquid root rises to the local minimum in the cubic function, then becomes imaginary as the local minimum detaches from the *x* axis. As the composition approaches pure nitrogen, the local minimum disappears and there is only an inflection. A similar phenomenon occurs when the pressure is such that the vapor root disappears over a range of compositions. The problem is exacerbated near the critical point, where the distinctions between the phases are small and very sensitive to the trial pressure and composition. Gundersen has shown that convergence can be enhanced by taking the local extremum as the trial value for the missing density root [T. Gundersen, *Comp. Chem. Eng.* **6:** 245 (1982)]. This works as long as the local extremum exists. For computations near the critical region, it may be necessary to first locate the critical point pertaining to a particular *T* and *P*, then work backward to the conditions of interest. A pseudo-root technique can also be used [P. M. Mathias, J. F. Boston, and S. Watanasiri, *AIChE J.* **30:** 182–186 (1984)].

For a *BUBL P* calculation, the temperature and the liquid composition are known, and this fixes the location of the *PV* isotherm for the composition of the liquid phase (solid line). The problem then is to locate a second (dashed) line for a vapor composition such that the line contains a dew point *D* on its vapor segment that lies at the pressure of the bubble point *B* on the liquid segment of the solid line. This pressure is the phase equilibrium pressure, and the composition for the dashed line is that of the equilibrium vapor.

Because of limitations inherent in quadratic mixing and combining rules, such as those given by Eqs. (4-86) to (4-88), the equation-of-state approach has found primary application to systems exhibiting modest deviations from ideal solution behavior in the liquid phase, e.g., to systems containing hydrocarbons and cryogenic fluids. However, since 1990, extensive research has been devoted to developing mixing rules that incorporate the excess Gibbs energy or activity coefficient data available for many systems. The extensive literature on this subject is reviewed by Valderrama [*Ind. Eng. Chem. Res.* **42:** 1603–1618 (2003)] and by Twu, Sim, and Tassone [*Chem. Eng. Progr.* **98**(11): 58–65 (Nov. 2002)]. For example, the UNIFAC model has also been combined with the predictive Soave-Redlich-Kwong (PSRK) equation of state. The procedure is most completely described (with background literature citations) by Horstmann et al. [*Fluid Phase Equilib.* **227:** 157–164 (2005)]. The modified Huron-Vidal and Wong-Sandler methods are the primary examples of this approach. Using these methods, it is possible to describe complex phase behavior with similar accuracy to that of activity models. This may seem like a desirable "universal" theory. Unfortunately, solving the phase equilibrium problem is slower and less reliable than the gamma/phi approach because of the coupling between root selection, density iteration, and composition dependence when applying the equation of state approach.

**Solute/Solvent Systems—Henry's Law** Henry's law often provides a useful framework to correlate and understand solubilities, especially when the component concentrations are low or when solutes (e.g., ions or supercritical components) do not have a valid pure-component reference state. A prevalent example is the case of liquid solubility of "noncondensable" gases, i.e., components above their critical temperature such as the nitrogen in the methane + nitrogen discussed above. These gases are common to the vast majority of chemical processes because catalytic conditions are often at sufficiently high temperatures that gas by-products are formed, even in cases when gaseous species are not explicitly involved in the desired reactions. Consideration of gas solubilities is critical for safety, for example, when a total condenser is used in a downstream distillation column and the (small but finite) gases could accumulate overhead in the long term.

These considerations are best understood by examining the rigorous vapor-liquid phase-equilibrium relationship for the solute given by Eq. (4-136). Note the superscript in $\gamma^*$. This means that the liquid fugacity approaches $h_i$ at Henry's reference state, where $\gamma^*$ approaches unity. Since most systems exhibit positive deviations from ideal solution behavior, it is common for $\gamma^*$ to be less than unity while $\gamma$ (based on the Lewis-Randall perspective) is greater than unity, even for the same system. For nonreacting systems, Eq. (4-136) provides a powerful general framework to analyze and understand even subtle variations in solute solubility, and in many cases the simple, original Henry law may provide an adequate correlation. When a component follows Henry's law, the component activity coefficient must be normalized to approach unity at infinite dilution. The relation with the Lewis-Randall activity coefficient is

$$\ln \gamma_i^* = \ln \gamma_i - \ln \gamma_i^\infty \tag{4-199}$$

Because the Gibbs-Duhem equation is still valid, any activity model can be used as long as Eq. (4-199) is applied.

***Types of Henry Constant Data or Units of Measure*** Henry's notion that solute solubility is proportional to partial pressure is widely useful, and it has been successfully applied in many branches of science and engineering. Data for Henry constants are available from a wide variety of sources. Unfortunately, these data can be confusing and error-prone because of variations that arise from the culture of the disciplines, and the constants can be inverted relative to one another. Because Henry's constant varies over many orders of magnitude, errors of units are difficult to detect simply by inspection. This section presents some of the ways in which the equivalents of Henry's constant may be converted to the form of Eq. (4-136). To begin, we should note the form implied by Henry's original definition, which predominates in the older literature. These Henry's constants have been defined as *absorption coefficients*. For example, the Ostwald coefficient is defined as the volume of gas absorbed at a temperature and a reference pressure (typically 101 kPa) divided by the volume of the solvent at the same temperature and pressure. The Ostwald coefficient $L_i$ is quantitatively related to the Henry solubility constant by

$$L_i(T, P) = RT/(h_i V_S) \tag{4-200}$$

Note that the Ostwald coefficient varies inversely with Henry's constant. Calculation of the Ostwald coefficient from Henry's constant is illustrated in Table 4-3, which presents calculations of $L_i$ by Rettich et al. [*J. Chem. Thermo.* **32:** 1145 (2000)] for the solubility of oxygen in water. Note that the values decrease with increasing temperature, whereas the analog of vapor pressure would increase. The values of the saturated molar volume of water have been taken from the DIPPR 801 database. The Bunsen coefficient is a special case of the Ostwald coefficient where the temperatures are corrected to a reference value, usually 273.15 K. Other subtle variations in the definition of absorption coefficients are presented by Gamsjäger et al. [*Pure Appl. Chem.* **82:** 1137 (2010)].

**TABLE 4-3 Illustrative Example* of Using Eq. (4-200) to Calculate $L_i$ from $h_i$**

| Temperature (K) | $h_{O_2} \times 10^{-9}$ Pa | $L_{O_2}$ | $V_w$ ($m^3$/kmol) | $L_{O_2}$ from Eq. (4-200) |
|---|---|---|---|---|
| 283.15 | 3.2966 | 0.039627 | 0.018024 | 0.039622 |
| 298.15 | 4.4038 | 0.031153 | 0.018071 | 0.031151 |
| 313.15 | 5.3985 | 0.026561 | 0.018158 | 0.026561 |
| 328.15 | 6.1917 | 0.024104 | 0.018278 | 0.024108 |

$V_w$ = molar volume of water

*Data (columns 1 to 3) have been taken from Rettich et al. for the solubility of oxygen in water, and the molar volumes of water are from the DIPPR 801 database. The fifth column shows calculations of $L_{O_2}$ by Eq. (4-200).

The most common modern variation of Eq. (4-136) is to change the liquid composition from mole fraction to molarity or molality, and here the units of Henry's constant change from pressure to pressure divided by concentration. In the many cases, the solvent is water, so commonly that it may be (questionably) taken for granted that the solvent is water when referring to Henry's law. In this common form, concentrations are assumed dilute such that $\gamma_i^* \approx 1$ and pressures are low. Then in molarity units

$$y_i P = h_i^C C_i \tag{4-201}$$

where $C_i$ is the concentration (mol/L) of the solute in the aqueous liquid phase. This is the form of Henry's law encountered in environmental applications (Sec. 22) and distillation involving gases (Sec. 13).

Another common form of Henry's law is in the form of the Henry's solubility constant, here written using concentration units of molality

$$k_H = m_i/(y_i P) \quad \text{or} \quad y_i P = (1/k_H) m_i \tag{4-202}$$

This form is tabulated in the NIST Chemistry Webbook [R. Sander, "Henry's Law Constants" in NIST Chemistry Webbook, NIST Standard Reference Database Number 69, eds. P. J. Linstrom and W. G. Mallard, National Institute of Standards and Technology, Gaithersburg, Md., 20899, http://webbook.nist.gov (retrieved November 8, 2016)]. Readers are cautioned that the symbols for Henry's constants are inconsistent in the literature. Here we use $h_i$ as the volatility constant, and we use $k_H$ for the solubility constant. In the atmospheric literature, $H_i$ is used for the solubility constant and $K_H$ for the volatility constant [Sander, *Atmos. Chem. Phys.* **15:** 4399–4981 (2015)]. Units must be included and consulted to avoid misapplication.

In general, specific applications can be expected to have dedicated computerized databases that serve them best, with coverage of compounds peculiar to those applications. In cases where LLE data are available but not Henry's constants, Henry's constant can be estimated by

$$h_i = [(1 - x_w^O)\, P_i^{\text{sat}}]/x_i \tag{4-203}$$

where $x_w^O$ is the equilibrium mole fraction of water in the organic phase (often negligible), $P_i^{\text{sat}}$ is the vapor pressure of the organic solute, and $x_i$ is the equilibrium mole fraction of the solute in the water phase. Any single tabulated Henry constant is published with its measurement temperature, typically 20 or 25°C.

Table 4-4 provides guidance on the conversion factors to use when the Henry's constant is provided in units including the liquid-phase concentration. Note that the conversion factor includes the molecular weight of the solvent when molality units are used, and it becomes temperature-dependent when molarity units are used since the solvent density at the temperature of interest is needed.

**TABLE 4-4 Factors to Convert Henry's Constant to the One Defined by Eq. (4-125) When Unit of Liquid Concentration Changes**

| Type of liquid concentration | Units of Henry constant | Conversion factor | Specific conversion factor with water as solvent | Comment |
|---|---|---|---|---|
| Mole fraction [Eq. (4-125)] | Pa | 1 | 1 | — |
| Molality | Pa · kg/mol | $1000/MW_{solvent}$ | 55.508 | Water MW is 18.015 |
| Molarity | Pa · m³/mol | $1000 \times \rho_{solvent}$ | 55,339 | Water as solvent at 298.15 K, with density of 55.339 kmol/m³ |

***Example 4-12 Solubility of Oxygen in Water by Henry's Law*** The NIST Webbook lists Henry's solubility constant for oxygen as 0.0013 mol/(kg · bar) at 25°C and the derivative $d(\ln k_H)/d(1/T)$ as 1700 K. Estimate the solubility of oxygen in water at 1 bar and 35°C in ppm by weight (ppmw), assuming air is 21 mol% oxygen.

*Solution* $k_H(35°C) = 0.0013 \exp[1700(1/308.15 - 1/298.15)] = 0.00108$ mol/kg · bar. For this instance of Henry's law, $\hat{f}_i = y_i P = m_i/k_H$, where $m_i$ is the molality of $O_2$. Solving gives $m_i = 0.21(1)0.00108 = 0.00023$ mol/kg. Converting to a mass basis, $0.00023 \cdot 0.032$ kg/mol = 7.3 ppmw, where we have neglected the contribution of the mass of oxygen to the total mass of the solution. Note that $k_H$ decreased as the temperature increased for oxygen in water, causing the molality, and hence the ppmw, to decrease. For some solutes, e.g., hydrogen, the solubility may actually increase with increases in temperature.

***Temperature Dependence of Henry Constants*** Henry constants have a significant nonlinear temperature dependence, and ignoring the temperature dependence usually leads to large inaccuracies. Smith and Harvey [*Chem. Eng. Progr.* **103:** 33 (2007)] provide guidance on ways to estimate the temperature dependence of Henry constants. They noted that for subcritical solutes, Henry constants may be approximated as the product of the vapor pressure and the infinite-dilution activity coefficient

$$h_i = \gamma_i^{\infty} P_i^{\text{sat}} \tag{4-204}$$

If the change in activity coefficient with temperature is small compared to the change in vapor pressure with temperature, then

$$h_i(T_2) = h_i(T_1)(P_2^{\text{sat}}/P_1^{\text{sat}}) \tag{4-205}$$

The simple extrapolation method is quite good up to 50°C and reasonable up to 80°C, though improved results are given by including θ discussed in the section *Temperature Dependence of Infinite-Dilution Activity Coefficients*. However, the vapor pressure–based extrapolation method is poor when Henry's constant goes through a maximum, as often occurs, even for subcritical components. For gaseous components, Henry constants generally go through a maximum, as shown for $CO_2$ [Smith and Harvey, *Chem. Eng. Progr.* **103:** 33 (2007)]. Figure 4-4, adapted from Smith and Harvey, shows the behavior of Henry's constant for toluene in water using Eq. (4-205) and also by Eq. (4-204) calculating the infinite-dilution activity coefficients as a function of temperature. Activity coefficients are difficult to predict accurately at higher temperature (as depicted by the dashed lines), and hence the uncertainty of the Henry's constant estimate also rises. It is thus better if an estimate of the temperature dependence of the activity coefficient is also used. Hwang et al. [*Ind. Eng. Chem. Res.* **31:** 1759, 1992] studied steam stripping of organic pollutants from water and showed that using the temperature dependence of the activity coefficient estimated by the UNIFAC group-contribution method often enables an improved way to estimate the temperature dependence of $h_i$. An improved method is referenced in the section *Temperature Dependence of Infinite-Dilution Activity Coefficients*. If data are available over a wide range of temperatures or if the temperature dependence of Henry's constant is being fit to data, an extended equation for the temperature dependence may be used. For example, Henry's constant for $H_2S$ in $H_2O$ is given by

$$h_i(\text{Pa}, T \text{ in K}) = 475.175 - 16{,}752.5/T - 74.904 \ln T + 0.086193T \tag{4-206}$$

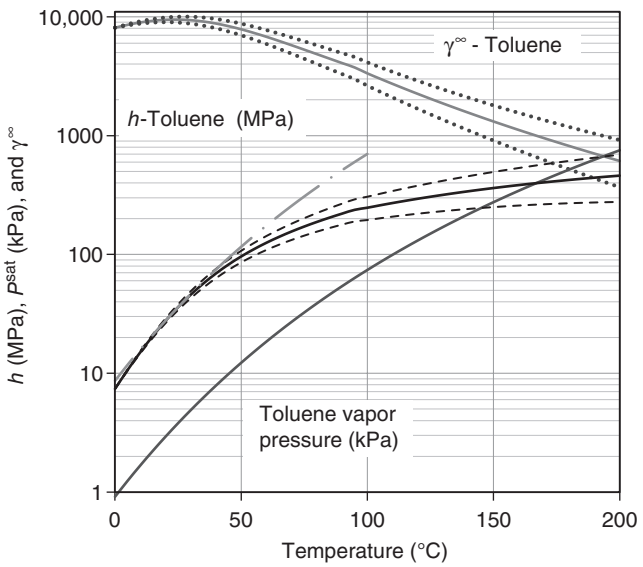

**FIG. 4-4** Temperature dependence of Henry's constant for toluene in water, showing the performance of the vapor-pressure extrapolation method starting at 25°C compared to the full calculation including the temperature dependence of the activity coefficient. The dash-dot line is extrapolated as explained in the text. The dotted and dashed lines show uncertainty in $\gamma^{\infty}$ and $h$.

***Extension of Henry's Law to Multicomponent Systems*** Broadly, Henry's constant is an infinite-dilution property that changes when other solutes (e.g., salts) or solvents are added. The Henry constant data may be available in pure solvents when Henry's constant in the mixed solvent is needed. The solubility of gaseous solutes in aqueous solutions was first studied over a century ago by Setchenow [*Ann. Chim. Phys.* **25:** 226 (1892)]. He developed the following expression:

$$h_i = h_i^\circ \exp(kC_S) \tag{4-207}$$

where $h_i^\circ$ is Henry's constant in the pure solvent, $C_s$ is the concentration (e.g., mol/L) of the additive (usually a salt), and $k$ is an empirical parameter. If $k$ is positive, increased concentration of the additive increases Henry's constant, and this is referred to as "salting out." This is the common case since a negative $k$ or "salting in" is rare.

Carroll [*Chem. Eng. Progr.* **88:** 53 (1992)] has discussed in detail the extension of Henry's law to multicomponent systems. Carroll illustrated salting out by using the data of Gamsjäger and Schindler [*Helv. Chim. Acta* **52:** 1395 (1969)] for the effect of dissolved NaCl on Henry's constant of $H_2S$ in $H_2O$. Setchenow's simple correlation with $k = 0.1742$ provides a good fit of the data. Dankwerts [*Gas-Liquid Reactions*, McGraw-Hill, New York, 1970, p. 18] provided a correlation to estimate $k$, and in this particular case Carroll (1992) noted that the predicted value of $k = 0.182$ enables an accurate estimate. Finally, note that Henry's constant of $H_2S$ in pure $H_2O$ is 543 bar, and this value agrees within 10 percent with the value of 600 bar calculated by Eq. (4-206), and this is typical of the uncertainty of Henry constant data.

O'Connell and Prausnitz [*Ind. Eng. Chem. Fundam.* **4:** 347 (1964)] derived an equation for Henry's constant of solute $i$ in a binary solvent consisting of components 1 and 2:

$$\ln h_i = x_1 \ln h_i^{(1)} + x_2 \ln h_i^{(2)} + a_{12} x_1 x_2 \tag{4-208}$$

where $h_i^{(1)}$ and $h_i^{(2)}$ are Henry constants of solute $i$ in solvents 1 and 2, respectively, and $a_{12}$ is a semiempirical parameter representing the interactions between the solvent species. This approximation has been evaluated by analyzing Henry constants at 20°C of methane in methanol-water and ethanol-water mixtures reported by Tokunaga and Kawai [*J. Chem. Eng. Japan* **8:** 326 (1975)]. Experience indicates that Eq. (4-208) enables a good fit, and Carroll (1992) has shown how the equation can be extended to multicomponent solvents, but, in general, some mixed solvent data are needed to establish the value of $a_{12}$.

***Sources of Henry Constant Data*** There are many useful sources of Henry constant data. An excellent source is Sec. 2 of this handbook, and the references provided there. Water is a very important solvent due to its environmental importance, and many sources of Henry's constants in water are available, for example, the extensive compilation by Sander [*Atmos. Chem. Phys.* **15:** 4399 (2015)]. The technical literature is vast, and many search engines are available, e.g., Google Scholar, but the ThermoLit resource generally provides the most reliable place to start. Henry's constants are also available through commercial process simulators, but these values need to be validated using literature or proprietary sources.

***Predictions of Henry Constants for Gaseous Species*** Another problem lies in predicting Henry constants in the absence of experimental data. A convenient equation for estimating gas fugacities in the Lewis-Randall perspective is

$$\log(f_i^L/P_c) = 7(1+\omega)(1-1/T_r)/3 - 3\exp(-E^H/T_r) \tag{4-209}$$

where $E^H = 3$ for most compounds. For $\omega = 0.21$, this equation reproduces the correlation of Prausnitz and Shair [*AIChE J.* **7:** 682 (1961)], effectively extrapolating the shortcut vapor pressure equation. Note that this approach applies the Lewis-Randall perspective, so $h_i = f_i^L \gamma_i^\infty$. Similar correlations have been suggested by Grayson and Streed [Paper 20-PO7, 6th World Petroleum Conference, Frankfurt, June 1963], and Chao and Seader [*AIChE J.* **7:** 598 (1961)]. A graph of this correlation shows that the component fugacity actually decreases with increasing temperature for $T_r > \sim 2$ (see Fig. 4-8). This behavior is counterintuitive, but it is also borne out in EOS models of gas solubility. For a component such as hydrogen, the gas solubility increases with increasing temperature at all common conditions, although it is generally quite a small solubility nevertheless. To obtain a general estimate of Henry's constant, it is necessary to include an estimate for the activity coefficient at infinite dilution. Readers should experiment with their process simulators to infer how gaseous species are treated by comparing multiple solvents and models such as UNIFAC and NRTL. As an example, Henry's constants for $H_2$ in paraffins can be estimated by Eq. (4-209) with $E^H = 14.1$, $T_c^{H_2} = 42$ K, $P_c^{H_2} = 19$ bar, $\omega^{H_2} = 0$, and an expression developed by regressing infinite-dilution activity coefficients:

$$\text{For } H_2\text{: } \ln(\gamma^\infty) = [3.15 - \ln(M_w^{\text{solv}})]\,(1 - T_c^{\text{solv}}/T) \tag{4-210}$$

where $M_w^{\text{solv}}$ and $T_c^{\text{solv}}$ are the molecular weight and critical temperature of the solvent. These pseudocritical constants for $H_2$ were adapted from Prausnitz, Lichtenhaler, and Azevedo (1999, pp. 172–173).

***Example 4-13 Solubility of Hydrogen in Hydrocarbons*** Estimate the mass fraction of hydrogen in *n*-hexadecane and *n*-triacontane at 50°C and 100 bar.

*Solution* At these conditions, we can ignore the composition of the solvent in the vapor phase. Applying the pseudocritical constants in Eq. (4-209), $1/T_r = 42/323.15 = 0.447$, $f_i^L = (19)10^{[7(1-0.447)/3-3\exp(-14.1(0.447))]} = 674$ bar. By Eq. (4-210), $\gamma^\infty = \exp[(3.15 - \ln 226)(1-723/323.15)] = 16.6$; $f_i = 100 = 674(16.6)x_i$. Solving gives $x_i = 100/(674 \cdot 16.6) = 0.0089$. Converting to mass fraction, we obtain 82 ppmw. Repeating for triacontane, we obtain $\gamma^\infty = 106$ and 6.6 ppmw. The value of 82 for hexadecane compares to 54 ppmw estimated by the method of Trinh et al, *J. Chem. Eng. Data* **61:** 19 (2016).

An alternative to using a hypothetical liquid fugacity such as the Prausnitz and Shair approach is to examine the bubble pressure in the dilute limit using an EOS approach. An estimate of Henry's constant can be inferred by effectively simulating the experimental conditions using an EOS model. Generally, this approach would be most amenable to the Lewis-Randall perspective. It has been observed that EOS models can reproduce the observed maximum in Henry's constant for gaseous components, at least qualitatively.

## LIQUID/LIQUID AND VAPOR/LIQUID/LIQUID EQUILIBRIA

Equation (4-127) is the basis for both liquid/liquid equilibria (LLE) and vapor/liquid/liquid equilibria (VLLE). Thus for LLE with superscripts $\alpha$ and $\beta$ denoting the two phases, Eq. (4-127) is written as

$$\hat{f}_i^\alpha = \hat{f}_i^\beta \qquad i = 1, 2, \ldots, N \tag{4-211}$$

Using modified Raoult's law for fugacities and canceling the $P_i^{\text{sat}}$ values gives

$$x_i^\alpha \gamma_i^\alpha = x_i^\beta \gamma_i^\beta \qquad i = 1, 2, \ldots, N \tag{4-212}$$

For most LLE applications, the effect of pressure on $\gamma_i$ can be ignored, and Eq. (4-212) then constitutes a set of $N$ equations relating equilibrium compositions to one another and to temperature. For a given temperature, solution of these equations requires a single expression for the composition dependence of $G^E$ suitable for both liquid phases. Not all expressions for $G^E$ suffice, even in principle, because some cannot represent liquid/liquid phase splitting. The UNIQUAC equation is suitable, and therefore prediction is possible by UNIFAC models. A special table of parameters for LLE calculations is given by Magnussen et al. [*Ind. Eng. Chem. Process Des. Dev.* **20:** 331–339 (1981)].

A comprehensive treatment of LLE is given by Sorensen et al. [*Fluid Phase Equilibr.* **2:** 297–309 (1979); **3:** 47–82 (1979); **4:** 151–163 (1980)]. Data for LLE are collected in a three-part set compiled by Sorensen and Arlt [*Liquid-Liquid Equilibrium Data Collection*, Chemistry Data Series, vol. 5, parts 1–3, DECHEMA, Frankfurt am Main, 1979–1980]. For vapor/liquid/liquid equilibria, Eq. (4-127) becomes

$$\hat{f}_i^\alpha = \hat{f}_i^\beta = \hat{f}_i^\upsilon \qquad i = 1, 2, \ldots, N \tag{4-213}$$

where $\alpha$ and $\beta$ designate the two liquid phases. With activity coefficients applied to the liquid phases and fugacity coefficients to the vapor phase, the $2N$ equilibrium equations for subcritical VLLE are

$$\left.\begin{aligned} x_i^\alpha \gamma_i^\alpha f_i^\alpha &= y_i \hat{\phi}_i P \\ x_i^\beta \gamma_i^\beta f_i^\beta &= y_i \hat{\phi}_i P \end{aligned}\right\} \quad \text{all } i \tag{4-214}$$

As for LLE, an expression for $G^E$ capable of representing liquid/liquid phase splitting is required; as for VLE, a vapor-phase equation of state for computing the $\hat{\phi}_i$ is also needed.

## TRENDS IN PHASE BEHAVIOR

Thermophysical properties usually and fortunately fall into regular patterns within and among families of compounds, and these patterns are useful to fill gaps in measurements, to identify outliers that are likely in error, and to educate chemical engineers to anticipate expected behaviors. This idea is especially attractive today because large databases of thermophysical properties are widely available. These databases can easily generate patterns, but also should be tested to identify errors and outliers. The patterns of behavior are more evident for fluid properties than for solid properties. This section provides representative examples of property patterns for the phase behavior of pure fluids and mixtures.

### PURE FLUIDS

Figure 4-5 presents a plot of vapor pressures for the 1-alcohols from methanol to 1-docosanol ($C_{22}H_{46}O$), where the data have been taken from the DIPPR 801 database [R. L. Rowley et al., *DIPPR Data Compilation of Pure Chemical Properties*, Design Institute for Physical Properties, AIChE, New York, 2006]. Korsten [*Ind. Eng. Chem. Res.* **39:** 813 (2000)] relates the slopes to the molecular weight within each functional class, and suggests that $\log P^{sat}$ versus $1/T^{1.3}$ is linear, though deviation is evident in Fig. 4-5. Although patterns are evident for fluid properties like the critical points, a pattern is usually not evident for solid properties like the triple point. Extrapolation of the vapor pressures above the critical temperature suggests that they meet at the "infinite point," which was first suggested by Cox [*Ind. Eng. Chem.* **15:** 592 (1923)]. The infinite point remains useful as a visualization tool for the vapor pressures of a family of compounds since it illustrates and explains the rule of thumb that "experimental vapor pressures of a family of compounds do not cross." The extrapolated vapor pressures cross at a hypothetical temperature higher than all the critical temperatures of the members of the family. The pattern is useful to interpolate for missing family members.

Another useful pattern is illustrated in the Othmer plot [*Ind. Eng. Chem.* **32:** 841 (1940)] of vapor-pressure ratios. Figure 4-6 presents the ratio of the vapor pressure of the 1-alcohols to that of water plotted against the vapor pressure of water. For each point on the curve, the same temperature is used to calculate the vapor pressure of the 1-alcohol and water. The chart provides useful education about relative vapor pressures and enthalpies of vaporization (related to the slope of the vapor-pressure curve by the Clausius-Clapeyron equation). Methanol and ethanol have higher vapor pressures than water, and the slopes of their Othmer curves are negative, which means that their enthalpies of vaporization are lower than that of water. The vapor pressure of 1-propanol is very close to that of water, and so is its enthalpy of vaporization. The higher alcohols exhibit successively decreasing vapor pressures and also successively increasing enthalpies of vaporization. The Othmer chart also provides the relative volatility under the ideal solution assumption.

### MIXTURES

Solvents such as dimethyl formamide (DMF) and acetonitrile (ACN) are used in extractive-distillation processes that recover 1,3-butadiene from steam-cracker hydrocarbons. Extractive distillation requires accurate correlation of the activity coefficients because the vapor pressures of the hydrocarbons in the feed mixture are very close, which facilitates azeotrope formation, and the basis of extractive distillation is the varying activity coefficients of the different hydrocarbons in the polar solvents. Table 4-5 presents experimental data for the infinite-dilution activity coefficients of various hydrocarbons in DMF and ACN at 313 K, which has been chosen as a representative value since it is typical of temperatures encountered in butadiene extractive-distillation columns. The infinite-dilution activity coefficients have been reported here since at plant conditions the solubility of the hydrocarbons in the liquid phase is relatively low. Table 4-5 demonstrates that the data fall into the pattern expected from "thermodynamic intuition." The infinite-dilution activity coefficients progressively decrease as the hydrocarbon class goes from paraffin to olefin to diolefins to triple bond to olefin plus triple bond. This, of course, is the reason why DMF and ACN are effective as extractive solvents, but the fact that the activity coefficients fall into the expected pattern provides confidence in the experimental data and offers a method to fill in data gaps. Figure 4-7 graphically illustrates

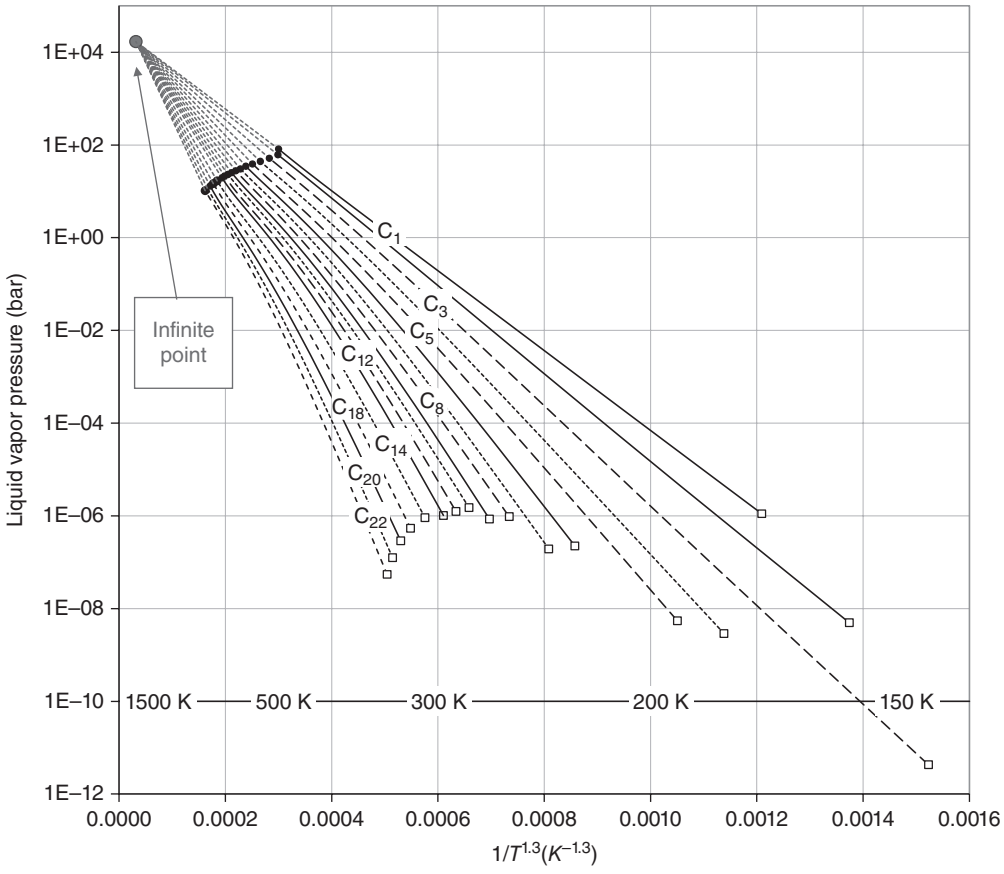

**FIG. 4-5** Vapor pressures of the 1-alcohols, including the critical points (solid circles •) and triple points (open squares □).

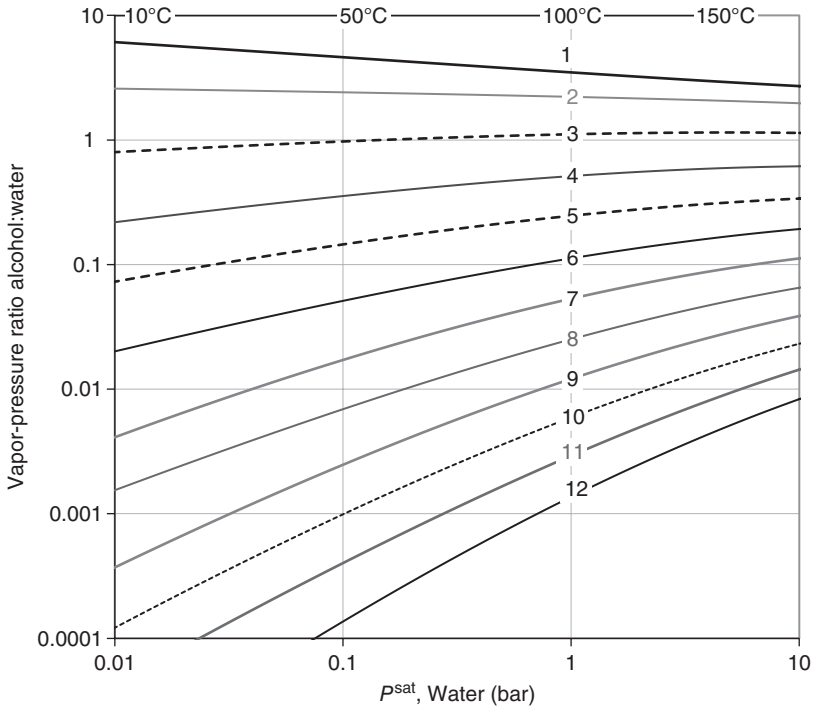

**FIG. 4-6** Ratio of vapor pressure of the 1-alcohols to that of water plotted versus the vapor pressure of water. The numbers on each curve show the carbon number of the alcohol. The temperatures at the top of the chart correspond to the water saturation temperature.

**TABLE 4-5 Infinite-Dilation Activity Coefficients at 313 K of Hydrocarbons in DMF and ACN**

| Compound | $\gamma^{\infty}$ in DMF | $\gamma^{\infty}$ in ACN | Class of hydrocarbon |
|---|---|---|---|
| Vinyl acetylene | 0.84 | 1.78 | Olefin and triple bond |
| 1-Propyne | 1.09 | 1.95 | Triple bond |
| 1-Butyne | | 2.98 | |
| 1,3-Butadiene | 2.38 | 3.73 | Diolefin |
| 1,2-Butadiene | 2.8 | | |
| *cis*-2-Butene | 4.51 | 7.44 | Olefin |
| 1-Butene | 4.97 | 7.22 | |
| Isobutene | 5.21 | | |
| *trans*-2-butene | 6.46 | | |
| Butane | 10.4 | 10.4 | Paraffin |
| Isobutane | 13.5 | 12.2 | |

the relationship among the infinite-dilution activity coefficients of hydrocarbons in DMF, ethanol, and water compared to that in ACN. Clearly, the regularity of the data itself—without any theoretical model—reveals a simple, clear pattern that helps to evaluate the consistency of the various data sources and also to fill in data gaps as needed. As an example, it is easy to estimate the infinite-dilution activity coefficient of 1-butyne in DMF, and of 1,2-butadiene, isobutene, and *trans*-2-butene in ACN. For 1-butyne in DMF, taking the value of ln(2.98) = 1.1 from Table 4-5, the y-axis indicates a value of 0.7 for the log value, or 2.0 for the activity coefficient.

Figure 4-8 graphically presents Harvey's correlation [*AIChE J.* **42:** 1491 (1996)] for Henry constants of 12 solutes in hexadecane. Solutes with large Henry constants (low solubility) typically have a negative slope with temperature, which means that the heat of solution is endothermic. As Henry's constant of a solute decreases, the slope becomes increasingly positive, which relates to exothermic absorption. At a sufficiently high temperature, close to the critical temperature of the solvent, most curves have negative slopes, and hence the solutes with low Henry's constants go through a maximum. Figure 4-9 studies the pattern of Henry's constants of various solutes in hexadecane (a variation on Fig. 4-8) by plotting the Henry constant, at a representative temperature of 350 K, versus the solute normal boiling point. (Note that

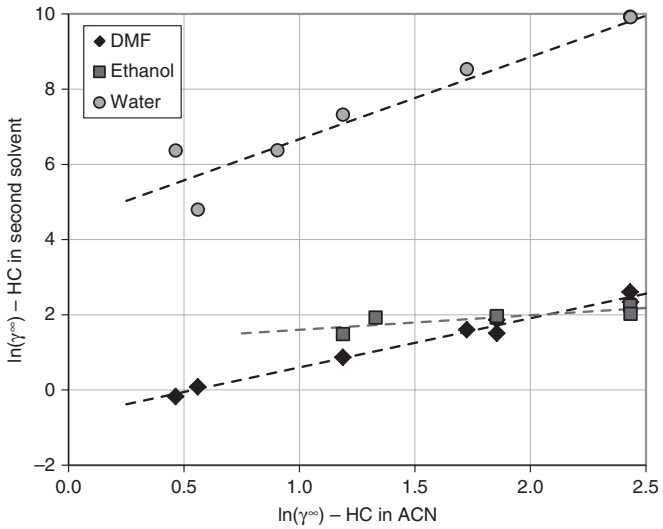

**FIG. 4-7** Correlation between hydrocarbon infinite-dilution activity coefficients in dimethyl formamide (DMF), ethanol, and water compared to those in acetonitrile (ACN). All activity coefficients are at 313 K. The dashed lines are best-fit straight lines.

$CO_2$ is a solid when its vapor pressure is atmospheric, hence an "effective" liquid normal boiling point of 183.7 K was estimated by extrapolating the liquid vapor pressure down to a vapor pressure of 1 atm.) Figure 4-9 indicates that for nonpolar compounds the logarithm of Henry constants at 350 K varies approximately linearly with the normal boiling point. Henry constants of the polar compounds ($CO_2$, HCl, $H_2S$, $NH_3$, and $SO_2$) are higher than the value based upon the nonpolar estimate, which indicates that they have relatively higher positive deviations from ideality in the nonpolar solvent, hexadecane. Hydrogen is another exception to the simple pattern, and this is likely because of quantum effects in its boiling behavior.

Figure 4-10 presents the aqueous infinite-dilution activity coefficients in water of substances from several families of organic compounds plotted versus their respective normal boiling temperatures. A temperature of 348 K

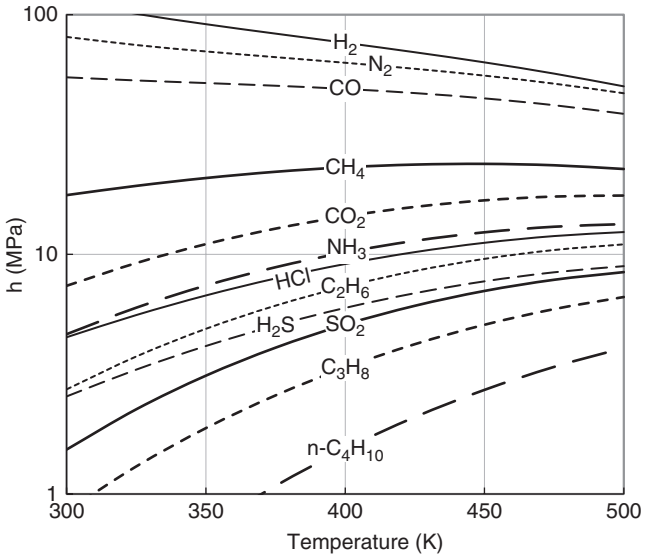

**FIG. 4-8** Henry's constants for various solutes in hexadecane.

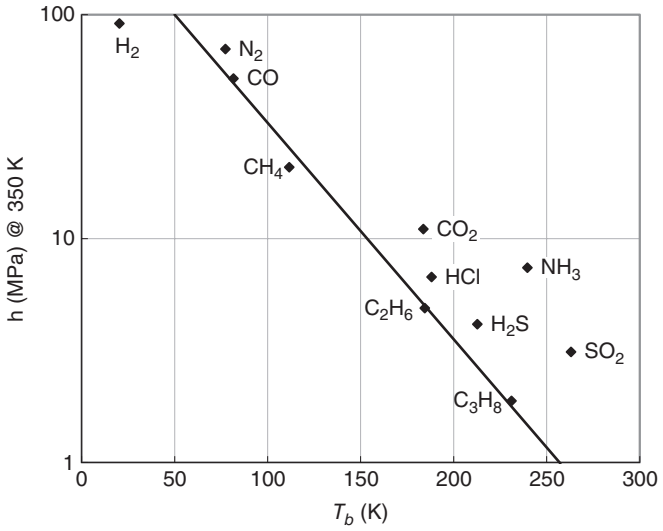

**FIG. 4-9** Henry's constants at 350 K of various solutes in hexadecane. The line is based upon the nonpolar solutes and assumes that the logarithm of Henry's constant at 350 K varies linearly with the normal boiling temperature.

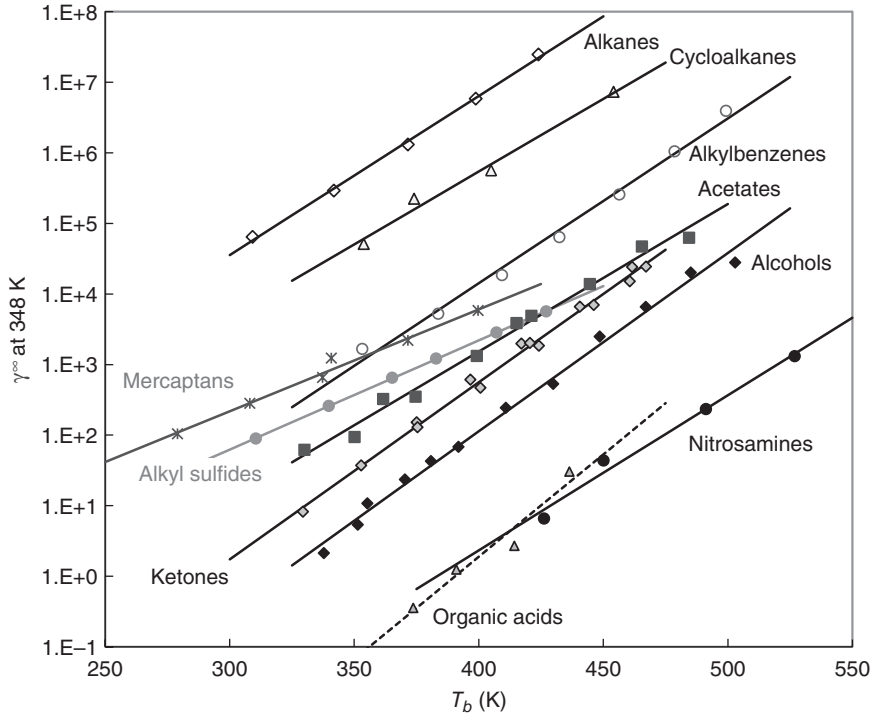

**FIG. 4-10** Infinite-dilution activity coefficients at 348 K of substances from various families of compounds in water. The lines are best fits for each compound, assuming that $\ln \gamma^{\infty}$ varies linearly with the solute normal boiling point.

has been chosen to represent separations where the water concentration is fairly high and the pressure is close to atmospheric; however, the patterns are relatively insensitive to temperature. These patterns help chemical engineers estimate the nonideality of the organic-water pair of particular interest and also identify data that may be in error. The variation of infinite-dilution activity coefficients is extremely large, ranging from organic acids that form nearly ideal mixtures with water to alkane-water mixtures where the activity coefficients are more than 7 orders of magnitude higher. The patterns accentuated by Fig. 4-10 are useful to develop correlations for aqueous separations in emerging biotechnology processes and to evaluate predictive techniques.

The results in Fig. 4-10 may be used to calculate relative volatilities in water at infinite dilution, which is approximately equal to the activity coefficient multiplied by the ratio of the solute and water vapor pressures. These results are very useful in biofuels and biochemical processes since the initial separations are typically performed where the liquid concentrations are dominated by water (i.e., fermentation processes usually occur in relatively dilute aqueous solutions). Figure 4-11 presents relative volatilities at infinite dilution of various families of compounds in water. These results may be surprising and unexpected even to experienced chemical engineers. The relative volatility of most compounds at infinite dilution in water is greater than unity, and the relative volatility increases with the boiling point of the solute. The latter result occurs because as the size or molecular weight of the member of a particular family increases (recall that vapor pressures within a family rarely cross), its vapor pressure at the reference temperature (348 K) decreases, but the activity coefficient increases to a greater extent such that the relative volatility rises.

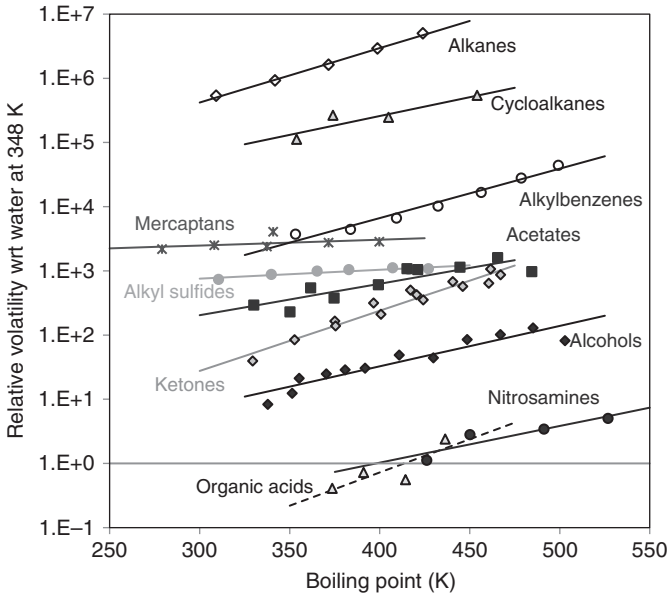

**FIG. 4-11** Relative volatilities with respect to (wrt) water for various families of compounds at infinite dilution in water. The relative volatilities have been calculated using the infinite-dilution activity coefficients from Fig. 4-10.

# TEMPERATURE DEPENDENCE OF INFINITE-DILUTION ACTIVITY COEFFICIENTS

## FUNDAMENTAL RELATIONSHIPS

Most activity coefficient models are concerned primarily with the effect of composition, giving only a rough approximation of the temperature dependence. However, the effect of temperature often is a critical factor in conceptual and process design. Fundamentally, the temperature dependence of $\gamma_{ij}^{\infty}$ is given by a version of the Gibbs-Helmholtz equation:

$$\left[\frac{\partial \ln \gamma_{ij}^{\infty}}{\partial(1/T)}\right]_{P,x} = \frac{\overline{H}_{ij}^{E,\infty}}{R} \tag{4-215}$$

where $\gamma_{ij}^{\infty}$ is evaluated at some constant composition for solute *i* in solvent *j*. Equation (4-215) is a version of Eq. (4-149). In cases where $\overline{H}_{ij}^{E,\infty}$ is known and its value is fairly constant over the temperature range of interest, integration allows convenient calculation:

$$\gamma_{ij}^{\infty}\Big|_{\text{at } T_2} \approx \gamma_{ij}^{\infty}\Big|_{\text{at } T_1} \exp\left[\frac{\overline{H}_{ij}^{E,\infty}}{R}\left(\frac{1}{T_2}-\frac{1}{T_1}\right)\right] \tag{4-216}$$

Compilations of available enthalpy of mixing data are given elsewhere (Onken, Rarey-Nies, and Gmehling, *Int. J. Thermophys.* **10**(3): 739–747 (1989); DDBST GmbH, http://www.ddbst.com; Christensen, Hanks, and Izatt, *Handbook of Heats of Mixing,* Wiley, New York, 1982); and Christensen, Rowley, and Izatt, *Handbook of Heats of Mixing, Supplemental Volume,* Wiley, New York, 1988)].

Equations (4-215) and (4-216) are the basis for many correlations of activity coefficient temperature dependence. Methods involving correlation of partial molar excess enthalpy are available for specific classes of compounds [Sherman et al., *J. Phys. Chem.* **99**(28): 11239–11247 (1995)]. Another method involves combining an excess Gibbs energy expression with an equation of state [Kontogeorgis and Coutsikos, *Ind. Eng. Chem. Res.* **51:** 4119–4142 (2012)].

An alternative approach to estimating $\gamma_{ij}^{\infty}$ as a function of temperature involves use of a power-law expression (or stretched exponential), given by

$$\ln \gamma_{ij}^{\infty} = a_{ij}(T_{ref}/T)^{\theta_{ij}} \tag{4-217}$$

where $T$ is temperature in Kelvin and $a_{ij}$ is a constant given by a known reference point, $a_{ij} = \ln \gamma_{ij}^{\infty}$ at $T = T_{\text{ref}}$ [Frank, Arturo, and Holden, *AIChE J.* **60:** 3675–3690 (2014)]. The exponent $\theta_{ij}$ is related to the partial molar excess enthalpy and entropy of mixing, such that

$$\theta_{ij} = \frac{1}{1-(T\overline{S}_{ij}^{E,\infty}/\overline{H}_{ij}^{E,\infty})} \tag{4-218}$$

In certain cases, Eq. (4-217) may be used to correlate data with a constant value of $\theta_{ij}$. In doing so, one assumes that the ratio of entropic to enthalpic terms is constant over the temperature range of interest. According to Frank et al. [*AIChE J.* **60:** 3675–3690 (2014)], a constant value of $\theta_{ij}$ is able to correlate $\gamma_{ij}^{\infty}$ for many binary types over a reasonably wide temperature span of 50°C to 80°C or more—at normal process conditions far from the critical point. Exceptions (in addition to near-critical mixtures) include a number of hydrogen bonding organic + water binaries such as $C_4$ to $C_7$ alcohols dissolved in water, 2-butanone in water, and acetonitrile in water. Water is included in the classification scheme as a solvent but not as a solute because of the many varied and difficult-to-predict ways water can form hydrogen bonds.

## CLASSIFICATION SCHEME

It is apparent from Eq. (4-218) that very different types of temperature dependence are possible depending on the signs and relative magnitudes of partial molar excess enthalpy and entropy. With this in mind, Frank et al. [*AIChE J.* **60:** 3675–3690 (2014)] have classified solute-solvent binary pairs into seven types corresponding to distinct domains of $\overline{H}_{ij}^{E,\infty}$, $\overline{S}_{ij}^{E,\infty}$, $\gamma_{ij}^{\infty}$, and $\theta_{ij}$ shown in Table 4-6. Specific interactions that can affect $\overline{H}_{ij}^{E,\infty}$ include static dipole-dipole (polarity effects), induced dipole-dipole, hydrogen bonding (proton donor and proton acceptor interactions), and electron donor/acceptor interactions. Factors affecting $\overline{S}_{ij}^{E,\infty}$ include segregation resulting from these interactions, molecular size differences, and the hydrophobic effect for organic + water mixtures.

In modeling phase equilibrium using the standard activity coefficient correlation equations, it is common practice to represent the effect of temperature for a given binary interaction parameter by using empirical expressions with two or more correlation constants. Typical expressions have the form $\ln A$ or $A = a + b/T + c \ln T$, where $A$ is a model parameter and $a$, $b$, and $c$ are correlation constants determined by fitting data, an expression derived from Eq. (4-215) assuming $\overline{H}_{ij}^{E,\infty}$ is a linear function of temperature. As an alternative, Frank et al. have proposed incorporating the parameter $\theta_{ij}$ directly into an excess Gibbs energy expression as shown in Table 4-7. In principle, suitable $\theta_{ij}$ values may be estimated via Eq. (4-218) by using molecular modeling methods to estimate the dimensionless ratio of $T\overline{S}_{ij}^{E,\infty}/\overline{H}_{ij}^{E,\infty}$, or $\theta_{ij}$ may be treated as adjustable model parameters in fitting data. The range of possible $\theta_{ij}$ values is bounded by the range of values given in Table 4-6 (at normal conditions). For nonaqueous binaries containing specific classes of compounds, estimates may be obtained from molecular structure using characteristic $\theta_{ij}$ values for various classes of compounds, as summarized in Table 4-8. Though developed

**TABLE 4-6 Classification of Activity Coefficient Temperature Dependence**

| Mixture type | Typical characteristics | Excess enthalpy and entropy $\bar{h}_{ij}^{E,\infty}$ | $\bar{s}_{ij}^{E,\infty}$ | Typical $\gamma_{ij}^{\infty}$ values* and change with temperature | Typical $\theta_{ij}$ values† |
|---|---|---|---|---|---|
| $\gamma_{ij}^{\infty} \approx 1$ | | | | | |
| I | Chemically similar, small molecules (nearly ideal) | $\approx 0$ | $\approx 0$ | $\gamma_{ij}^{\infty} \approx 1$ | $\theta_{ij} \approx 0$ |
| $\gamma_{ij}^{\infty} > 1$ | | | | | |
| II | Regular-solution-like | Pos. | Pos. | $1.2 < \gamma_{ij}^{\infty} < 1000$<br>$\frac{\partial \gamma_{ij}^{\infty}}{\partial T} < 0$ | $1 < \theta_{ij} < 5$ |
| III | Endothermic with negative excess entropy | Pos. | Neg. | $\gamma_{ij}^{\infty} > 2$<br>$\frac{\partial \gamma_{ij}^{\infty}}{\partial T} < 0$ | $0.15 < \theta_{ij} < 1$ |
| IV | Exothermic with negative excess entropy | Neg. | Neg. | $\gamma_{ij}^{\infty} > 2$<br>$\frac{\partial \gamma_{ij}^{\infty}}{\partial T} > 0$ | $-3 < \theta_{ij} < -0.3$ |
| $\gamma_{ij}^{\infty} < 1$ | | | | | |
| V | Net attractive interactions with negative excess entropy | Neg. | Neg. | $0.2 < \gamma_{ij}^{\infty} < 1$<br>$\frac{\partial \gamma_{ij}^{\infty}}{\partial T} > 0$ | $1 < \theta_{ij} < 5$ |
| VI | Net attractive interactions with positive excess entropy | Neg. | Pos. | $0.2 < \gamma_{ij}^{\infty} < 1$<br>$\frac{\partial \gamma_{ij}^{\infty}}{\partial T} > 0$ | $0.3 < \theta_{ij} < 1$ |
| VII | Chemically similar, wide molecular size distribution | Pos. | Pos. | $0.6 < \gamma_{ij}^{\infty} < 1$<br>$\frac{\partial \gamma_{ij}^{\infty}}{\partial T} < 0$ | $-5 < \theta_{ij} < -0.5$ |

*As a general rule, phase instability may occur at roughly $\gamma_{ij}^{\infty} \approx 7$ to 20 or $\ln \gamma_{ij}^{\infty} \approx 2$ to 3.

for $\gamma^{\infty}_{ij}$, applications at more concentrated conditions may be addressed using the standard correlation equations modified to incorporate $\theta_{ij}$ as indicated in Table 4-7. For the Wilson or NRTL equation, the original model temperature dependence is not used, and the temperature dependence of the parameters is determined by solving simultaneously the equations provided in the table. The resulting framework is intended for application-directed screening and modeling purposes, focusing on a limited temperature range of up to 80°C or so for a given application of interest.

# THERMODYNAMICS FOR CONCEPTUAL DESIGN

## PREDICTION OF SPECIES PARTITIONING

Several key quantities are useful in screening separation processes and potential use of extra solvents. The *K* factor provides the distribution of a single component, but the ratio of *K* factors provides superior insight. We have previously used the relative volatility, Eq. (4-184). Infinite-dilution activity coefficients can be leveraged for insight. In each of the relations below, the effect of temperature may be estimated by using the θ correction of the previous section [Frank, Arturo, and Holden, *AIChE J.* **60:** 3675–3690 (2014)]. For solvent selection for extractive or azeotropic distillation of components *i* and *j*, the relative volatility of the components in the solvent can be evaluated

$$\alpha^{\infty}_{ij} = \gamma^{\infty}_{i,\text{solv}} P^{\text{sat}}_i(T) / (\gamma^{\infty}_{j,\text{solv}} P^{\text{sat}}_j(T)) \tag{4-219}$$

When stripping a component from a solvent, the solvent is nearly pure, so the important quantity is

$$\alpha^{\infty}_{ij} = \gamma^{\infty}_{i,\text{solv}} P^{\text{sat}}_i(T) / (P^{\text{sat}}_j(T)) \tag{4-220}$$

When screening solvents for liquid-liquid extraction under dilute conditions, the LLE *K* ratio is used

$$K^{\infty}_{ij} = \frac{x_{i,\text{extract}}}{x_{i,\text{raffinate}}} = \frac{\gamma^{\infty}_{i,\text{raffinate}}}{\gamma^{\infty}_{i,\text{extract}}} \tag{4-221}$$

The concept of using ratios of *K* values as in the relative volatility can be generalized and is called the *separation factor*, representing the relative enrichment of a given component after one theoretical stage of contacting. For cosolutes *i* and *j*, and using *x* and *y* as generic compositions,

$$\alpha_{ij} = \frac{K_i}{K_j} = \frac{y^{\text{II}}_i / x^{\text{I}}_i}{y^{\text{II}}_j / x^{\text{I}}_j} = \frac{(y_i/y_j)^{\text{II}}}{(x_i/x_j)^{\text{I}}} \tag{4-222}$$

where I and II indicate the phase. For example, I is raffinate and II is extract in liquid extraction.

The enrichment of solute *i* with respect to solute *j* can be further increased with the use of multiple contacting stages. Additional discussion of distillation and extraction process fundamentals is given in Secs. 13 and 15.

# REACTING SYSTEMS

## CHEMICAL REACTION STOICHIOMETRY

For a phase in which a chemical reaction occurs according to the equation

$$|\nu_1| A_1 + |\nu_2| A_2 + \cdots \rightarrow |\nu_3| A_3 + |\nu_4| A_4 + \cdots$$

the $|\nu_i|$ are stoichiometric coefficients and the $A_i$ stand for chemical formulas. The $\nu_i$ themselves are called *stoichiometric numbers*, and associated with them is a sign convention such that the value is positive for a product and negative for a reactant. More generally, for a system containing *N* chemical species, any or all of which can participate in *r* chemical reactions, the reactions are represented by the equations

$$0 = \sum_i \nu_{i,j} A_i \qquad j = 1, 2, \ldots, r \tag{4-223}$$

where $$\text{sign}(\nu_{i,j}) = \begin{cases} -\text{ for a reactant species} \\ +\text{ for a product species} \end{cases}$$

If species *i* does not participate in reaction *j*, then $\nu_{i,j} = 0$.

The stoichiometric numbers provide relations among the changes in mole numbers of chemical species which occur as the result of chemical reaction. The change in moles for reaction *j* can be related to the change in a single quantity $\varepsilon_j$, called the *reaction coordinate* for reaction *j*.

$$\frac{dn_{1,j}}{\nu_{1,j}} = \frac{dn_{2,j}}{\nu_{2,j}} = \ldots = \frac{dn_{N,j}}{\nu_{N,j}} = d\varepsilon_j \tag{4-224}$$

If the initial number of moles of species *i* is $n_{i0}$ and if the convention is adopted that $\varepsilon_j = 0$ for each reaction in this initial state, then

$$n_i = n_{i_0} + \sum_j \nu_{i,j} \varepsilon_j \qquad i = 1, 2, \ldots, N \tag{4-225}$$

Equation (4-225) is the basic expression of material balance for a closed system in which *r* chemical reactions occur. It shows for a reacting system that at most *r* mole-number-related quantities $\varepsilon_j$ are capable of independent variation. It is not an equilibrium relation, but merely an accounting scheme, valid for tracking the progress of the reactions to arbitrary levels of conversion. The reaction coordinate has units of moles. A change in $\varepsilon_j$ of 1 mol signifies a *mole of reaction*, meaning that reaction *j* has proceeded to such an extent that the change in mole number of each reactant and product is equal to its stoichiometric number.

## CHEMICAL REACTION EQUILIBRIA

The general criterion of chemical reaction equilibria is given by Eq. (4-128). For a system in which just a single reaction occurs, incorporation of Eq. (4-224) leads to

$$\sum_i \nu_i \mu_i = 0 \tag{4-226}$$

Generalization of this result to multiple reactions produces

$$\sum_i \nu_{i,j} \mu_i = 0 \qquad j = \text{I}, \text{II}, \ldots, r \tag{4-227}$$

**Standard Property Changes of Reaction** For the reaction

$$aA + bB \rightarrow lL + mM$$

a *standard* property change is defined as the property change resulting when *a* mol of *A* and *b* mol of *B* in their standard states at temperature *T* react to form *l* mol of *L* and *m* mol of *M* in their standard states also at temperature *T*. A *standard state* of species *i* is its real or hypothetical state as a pure species at temperature *T* and at a standard state pressure $P^{\circ}$. The standard property change of reaction *j* is given by the symbol $\Delta M^{\circ}_j$, and its general mathematical definition is

$$\Delta M^{\circ}_j \equiv \sum_i \nu_{i,j} M^{\circ}_i \tag{4-228}$$

For species present as gases in the actual reactive system, the standard state is the pure *ideal gas* at pressure $P^{\circ}$. For liquids and solids, it is usually the state of pure real liquid or solid at $P^{\circ}$. The standard state pressure $P^{\circ}$ is

fixed at 1 bar. Note that the standard states may represent different physical states for different species; any or all the species may be gases, liquids, or solids.

The most commonly used standard property changes of reaction are

$$\Delta G_j^\circ \equiv \sum_i \nu_{i,j} G_i^\circ = \sum_i \nu_{i,j} \mu_i^\circ \tag{4-229}$$

$$\Delta H_j^\circ \equiv \sum_i \nu_{i,j} H_i^\circ \tag{4-230}$$

$$\Delta C_{P_j}^\circ \equiv \sum_i \nu_{i,j} C_{P_i}^\circ \tag{4-231}$$

The standard Gibbs energy change of reaction $\Delta G_j^\circ$ is used in the calculation of equilibrium compositions. The standard heat of reaction $\Delta H_j^\circ$ is used in the calculation of the heat effects of chemical reaction, and the standard heat capacity change of reaction is used for extrapolating $\Delta H_j^\circ$ and $\Delta G_j^\circ$ with $T$. Numerical values for $\Delta H_j^\circ$ and $\Delta G_j^\circ$ are computed from tabulated formation data, and $\Delta C_{P_j}^\circ$ is determined from empirical expressions for the $T$ dependence of the $C_{P_i}^\circ$ [see, e.g., Eq. (4-1)].

**Equilibrium Constants** For practical application, Eq. (4-227) must be reformulated. The initial step is elimination of the $\mu_i$ in favor of activities or fugacities. Equation (4-141) gives, upon rearrangement,

$$\sum_i [\nu_{i,j}(G_i^\circ + RT \ln a_i)] = 0$$

or

$$\sum_i \nu_{i,j} G_i^\circ + RT \sum_i \ln a_i^{\nu_{i,j}} = 0$$

or

$$\ln \prod_i a_i^{\nu_{i,j}} = \frac{-\sum_i \nu_{i,j} G_i^\circ}{RT}$$

where

$$a_i \equiv \frac{\hat{f}_i}{f_i^\circ} \tag{4-232}$$

The right side of this equation is a function of temperature only for given reactions and given standard states. Convenience suggests setting it equal to $\ln K_{a,j}$, whence

$$\prod_i a_i^{\nu_{i,j}} = K_{a,j} \text{ all } j \tag{4-233}$$

where, by definition, we have the activity-based equilibrium constant

$$K_{a,j} \equiv \exp\left(\frac{-\Delta G_j^\circ}{RT}\right) \tag{4-234}$$

Quantity $K_{a,j}$ is the chemical reaction equilibrium constant for reaction $j$, and $\Delta G_j^\circ$ is the corresponding standard Gibbs energy change of reaction [see Eq. (4-229)]. Although called a "constant," $K_{a,j}$ is a function of $T$, but only of $T$.

The activities in Eq. (4-233) provide the connection between the *equilibrium* states of interest and the *standard* states of the constituent species, for which data are presumed available. The standard states are always at the equilibrium temperature. Although the standard state need not be the same for all species, for a *particular* species it must be the state represented by both $G_i^\circ$ and the $f_i^\circ$ upon which activity $a_i$ is based.

The application of Eq. (4-233) requires explicit introduction of composition variables. For gas-phase reactions this is accomplished through the fugacity coefficient

$$a_i \equiv \frac{\hat{f}_i}{f_i^\circ} = \frac{y_i \hat{\phi}_i P}{f_i^\circ}$$

However, the standard state for gases is the ideal gas state at the standard state pressure, for which $f_i^\circ = P^\circ$. Therefore,

$$a_i = \frac{y_i \hat{\phi}_i P}{P^\circ}$$

and Eq. (4-233) becomes

$$\prod_i (y_i \hat{\phi}_i)^{\nu_{i,j}} \left(\frac{P}{P^\circ}\right)^{\nu_j} = K_{a,j} \text{ all } j \tag{4-235}$$

where $\nu_j \equiv \sum_i \nu_{i,j}$ and $P^\circ$ is the standard state pressure of 1 bar, expressed in the same units used for $P$. The $y_i$ may be eliminated in favor of equilibrium values of the reaction coordinates $\varepsilon_j$ (see Example 4-14). Then, for fixed temperature Eq. (4-235) relates the $\varepsilon_j$ to $P$. In principle, specification of the pressure allows solution for the $\varepsilon_j$. However, the problem may be complicated by the dependence of $\hat{\phi}_i$ on composition, i.e., on the $\varepsilon_j$. If the equilibrium mixture is assumed an ideal solution, then [Eq. (4-123)] each $\hat{\phi}_i$ becomes $\phi_i$, the fugacity coefficient of pure species $i$ at the mixture $T$ and $P$. An important special case of Eq. (4-235) results for gas-phase reactions when the phase is assumed an ideal gas. In this event $\phi_i = 1$, and

$$\prod_i (y_i)^{\nu_{i,j}} \left(\frac{P}{P^\circ}\right)^{\nu_j} = K_{a,j} \text{ all } j \tag{4-236}$$

For liquid-phase reactions, Eq. (4-233) is modified by introduction of the activity coefficient $\gamma_i = \hat{f}_i / x_i f_i$, where $x_i$ is the liquid-phase mole fraction. The activity is then

$$a_i \equiv \frac{\hat{f}_i}{f_i^\circ} = \gamma_i x_i \left(\frac{f_i}{f_i^\circ}\right)$$

Both $f_i$ and $f_i^\circ$ represent fugacity of pure liquid $i$ at temperature $T$, but at pressures $P$ and $P^\circ$, respectively. Except in the critical region, pressure has little effect on the properties of liquids, and the ratio $f_i/f_i^\circ$ is often taken as unity. When this is not acceptable, this ratio is evaluated by the Poynting equation, Eq. (4-67).

$$\ln \frac{f_i}{f_i^\circ} = \frac{1}{RT} \int_{P^\circ}^{P} V_i \, dP \cong \frac{V_i (P - P^\circ)}{RT}$$

When the ratio $f_i/f_i^\circ$ is taken as unity, $a_i = \gamma_i x_i$, and Eq. (4-233) becomes

$$\prod_i (\gamma_i x_i)^{\nu_{i,j}} = K_{a,j} \text{ all } j \tag{4-237}$$

Here the difficulty is to determine the $\gamma_i$, which depend on the $x_i$. In the case of an ideal Lewis-Randall solution, $\gamma_i = 1$, and Eq. (4-237) reduces to

$$\prod_i (x_i)^{\nu_{i,j}} = K_{a,j} \text{ all } j \tag{4-238}$$

The significant feature of Eqs. (4-236) and (4-238), the simplest expressions for gas- and liquid-phase reaction equilibrium, respectively, is that the temperature-, pressure-, and composition-dependent terms are distinct and separate.

The effect of temperature on the equilibrium constant is

$$\frac{d \ln K_{a,j}}{dT} = \frac{\Delta H_j^\circ}{RT^2} \tag{4-239}$$

For an endothermic reaction, $\Delta H_j^\circ$ is positive and $K_{a,j}$ increases with increasing $T$; for an exothermic reaction, it is negative and $K_{a,j}$ decreases with increasing $T$. After integration, the relation is

$$\ln K_a = \ln K_{a,T_0} - \frac{\Delta H_{T_0}^\circ}{R}\left(\frac{1}{T} - \frac{1}{T_0}\right) - \frac{1}{T}\int_{T_0}^{T} \frac{\Delta C_P^\circ}{R} dT + \int_{T_0}^{T} \frac{\Delta C_P^\circ}{R} \frac{dT}{T} \tag{4-240}$$

In the more extensive compilations of data, values of $\Delta G^\circ$ and $\Delta H^\circ$ for formation reactions are given for a wide range of temperatures, rather than just at the reference temperature $T_0 = 298.15$ K. [See in particular *TRC Thermodynamic Tables—Hydrocarbons* and *TRC Thermodynamic Tables—Non-hydrocarbons*, serial publications of the Thermodynamics Research Center, Texas A & M Univ. System, College Station, Tex.; "The NBS Tables of Chemical Thermodynamic Properties," *J. Phys. Chem. Ref. Data* **11**, supp. 2 (1982).] Where data are lacking, methods of estimation are available; these are reviewed by Poling, Prausnitz, and O'Connell, *The Properties of Gases and Liquids*, 5th ed., McGraw-Hill, New York, 2000, chap. 6. For an estimation procedure based on molecular structure, see Constantinou and Gani, *Fluid Phase Equilibr.* **103:** 11–22 (1995). See also Sec. 2.

***Example 4-14 Single-Reaction Equilibrium*** The hydrogenation of benzene to produce cyclohexane by the reaction

$$C_6H_6 + 3H_2 \rightarrow C_6H_{12}$$

is carried out over a catalyst formulated to favor this reaction. Operating conditions cover a pressure range from 10 to 35 bar and a temperature range from 450 to 670 K. The reaction rate increases with increasing $T$, but because the reaction is exothermic the equilibrium conversion decreases with increasing $T$. A comprehensive study of the effect of operating variables on the chemical equilibrium of this reaction has been published by J. Carrero-Mantilla and M. Llano-Restrepo [*Fluid Phase Equilibr.* **219:** 181–193 (2004)]. Presented here are calculations for a single set of operating conditions, namely, $T = 600$ K, $P = 15$ bar, and a molar feed ratio $H_2/C_6H_6 = 3$, the stoichiometric value. For these conditions we determine the fractional conversion of benzene to cyclohexane. Carrero-Mantilla and Llano-Restrepo express ln $K$ as a function of $T$ by an equation which for 600 K yields the value $K = 0.02874$.

A feed stream containing 3 mol $H_2$ for each 1 mol $C_6H_6$ is the *basis* of calculation, and for this single reaction, Eq. (4-225) becomes $n_i = n_{i0} + \nu_i\varepsilon$, yielding

$$\begin{aligned} n_B &= 1-\varepsilon && \text{benzene} \\ n_H &= 3-3\varepsilon && \text{hydrogen} \\ n_C &= \varepsilon && \text{cyclohexane} \\ \sum_i n_i &= 4-3\varepsilon \end{aligned}$$

Each mole fraction is therefore given by $y_i = n_i/(4-3\varepsilon)$.

Assume first that the equilibrium mixture is an ideal gas, and apply Eq. (4-236), written for a single reaction, with subscript $j$ omitted and $\nu = -3$:

$$\prod_i y_i^{\nu_i}\left(\frac{P}{P^\circ}\right)^{\nu} = \frac{\dfrac{\varepsilon}{4-3\varepsilon}}{\left(\dfrac{1-\varepsilon}{4-3\varepsilon}\right)\left(\dfrac{3-3\varepsilon}{4-3\varepsilon}\right)^3}\left(\frac{15}{1}\right)^{-3} = K = 0.02874$$

whence

$$\frac{\varepsilon}{1-\varepsilon}\left(\frac{4-3\varepsilon}{3-3\varepsilon}\right)^3 (15)^{-3} = 0.02874 \quad \text{and} \quad \varepsilon = 0.815$$

Thus, the assumption of ideal gases leads to a calculated conversion of 81.5 percent. Carrero-Mantilla and Llano-Restrep present results for a wide range of conditions, both for the ideal gas assumption and for calculations wherein $\hat{\phi}_i$ values are determined from the Soave-Redlich-Kwong equation of state. In no case are these calculated conversions significantly divergent from ideal gas results.

**Complex Chemical Reaction Equilibria** When the composition of an equilibrium mixture is determined by a number of simultaneous reactions, calculations based on equilibrium constants become complex and tedious. A more direct procedure (and one suitable for general computer solution) is based on minimization of the total Gibbs energy $G'$ in accord with Eq. (4-128). The treatment here is limited to gas-phase reactions for which the problem is to find the equilibrium composition for given $T$ and $P$ and for a given initial feed. The method requires constraints on the distribution of elements among the various species proposed to be present in the system.

1. Propose all species that are expected to be present at equilibrium.
2. Formulate the atom balance equations, based on conservation of the total number of atoms of each *element* in a system composed of $w$ elements. Let subscript $k$ identify a particular element, and define $A_k$ as the total number of atomic masses of the $k$th element in the feed. Further, let $a_{ik}$ be the number of atoms of the $k$th element present in each molecule of chemical species $i$. The material balance for element $k$ is then

$$\sum_i n_i a_{ik} = A_k \qquad k = 1,2,\ldots,w \tag{4-241}$$

3. Eliminate any atom balance constraints that are not unique.

The Gibbs energy of the system is calculated via

$$\underline{G} = \sum_{i=1}^{w} \mu_i n_i$$

The chemical potential is given by Eq. (4-141). For gas-phase reactions and standard states as the pure ideal gases at $P^\circ$, this equation becomes

$$\mu_i = G_i^\circ + RT \ln \frac{\hat{f}_i}{P^\circ}$$

If $G_i^\circ$ is arbitrarily set equal to zero for all *elements* in their standard states, then for compounds $G_i^\circ = \Delta G_{f_i}^\circ$, the standard Gibbs energy change of formation of species $i$ at the temperature of the system (*not* the reference temperature). In addition, the fugacity is expressed using the fugacity coefficient by Eq. (4-131), $\hat{f}_i = y_i\hat{\phi}_i P$. With these substitutions, the equation for $\mu_i$ becomes

$$\mu_i = \Delta G_{f_i}^\circ + RT \ln \frac{y_i\hat{\phi}_i P}{P^\circ} \tag{4-242}$$

The unknowns in these equations are the $n_i$ (note that $y_i = n_i/\Sigma_i n_i$), subject to the atom balance constraints. The problem is most readily solved using a computer. Modern spreadsheets provide constrained optimization. The minimization problem presented here using nonideal gases is best solved with a process simulator.

In this procedure, the question of what chemical reactions are involved never enters directly into any of the equations. However, the choice of a set of species is entirely equivalent to the choice of a set of independent reactions among the species. In any event, a set of species or an equivalent set of independent reactions must always be assumed, and different assumptions produce different results for each reacting system. For example, assuming carbon monoxide as a possible byproduct of a combustion reaction would result in a different equilibrium concentration than ignoring it. Another caveat is that the equilibrium calculation does not necessarily represent the reality of an actual process because there is no consideration of reaction kinetics. For example, though carbon formation is thermodynamically favorable when processing hydrocarbons at high temperatures, industrial processes are successfully run with limited carbon deposition or the catalysts are regenerated. The equilibrium calculations remain an important guideline to explore potential products and/or conversion limitations.

A detailed example of a complex gas-phase equilibrium calculation is given by Smith, Van Ness, and Abbott (2005, pp. 527–528). General application of the method to multicomponent, multiphase systems is treated by Iglesias-Silva et al. [*Fluid Phase Equilibr.* **210:** 229–245 (2003)] and by Sotyan, Ghajar, and Gasem [*Ind. Eng. Chem. Res.* **42:** 3786–3801 (2003)].

## HENRY'S LAW FOR REACTING SYSTEMS

Dissociation of weak electrolytes is best modeled as a reversible reaction involving simultaneous reaction and phase equilibrium. These kinds of problems arise in the treatment of acid gases and involve many of the most complex aspects of thermodynamic analysis. Speciation is an important issue that must be handled on a case-by-case basis. To illustrate, we consider a specific example, $H_2S$ absorption.

When the weak acid hydrogen sulfide ($H_2S$) is dissolved in water, it tends to dissociate into $HS^-$ and $S^{2-}$ anions, which are described by chemical equilibrium equations

$$H_2S + H_2O \leftrightarrow HS^- + H_3O^+ \qquad pK_a = 6.9 \tag{4-243}$$

$$HS^- + H_2O \leftrightarrow S^{2-} + H_3O^+ \qquad pK_a \sim 14 \tag{4-244}$$

The thermodynamic framework and electrolyte activity coefficient models through which chemical equilibrium equations are incorporated into the calculations are beyond the scope of the discussion here; interested readers should consult papers by experts such as Chen and coworkers [*Chem. Eng. Progr.* **111:** 65–75 (2015) and **112:** 3442 (2016)]. However, it should be understood that equations such as Eq. (4-136) relate to only the molecular form of species such as $H_2S$. At a given partial pressure of $H_2S$ in the gas phase, any dissociation will increase the "apparent concentration" in the liquid phase. At a given overall liquid concentration, the dissociation decreases the molecular (undissociated) concentration and fugacity, and thus the related vapor-phase concentration. For practical purposes, it is useful to define the apparent liquid mole fraction of dissociative species, denoted by the subscript 0, which includes all forms of a given solute. Because the moles are conserved in Eqs. (4-243) and (4-244), we may write

$$x_0(H_2S) \equiv x(H_2S) + x(HS^-) + x(S^{2-}) \tag{4-245}$$

Another useful practical definition is the *apparent Henry's constant*, which is the ratio of the partial pressure to the apparent liquid mole fraction at any equilibrium condition, related to Henry's constant in the following way

$$h_{0i} \equiv \frac{y_i P_i}{x_{0i}} = \frac{\gamma_i^*}{\hat{\phi}_i^V} h_i \exp\left[\frac{1}{RT}\int_{P_i^0}^{P} \overline{v}_i^\infty dP\right]\left\{\frac{x_i}{x_{0i}}\right\} \tag{4-246}$$

where $x_i$ is the mole fraction of the molecular undissociated species, $H_2S$ in this discussion. The significance of the definition of $h_{0i}$ in Eq. (4-246) is

that experimentally the vapor mole fraction and the overall liquid mole fractions appearing in the first equality are the most important quantities. For a practitioner, knowledge of the apparent Henry's constant facilitates rapid calculations. However, to determine the apparent Henry's constant, detailed calculations are required using the last equality. After the detailed calculations, if $h_{0i}$ is independent of $x_{0i}$ at a given temperature, then the first equality can be used. If not, then the more rigorous model must be used, and the results are conveniently expressed in terms of the apparent Henry's constant, even though the value is not always constant. The discussion here illustrates use of the apparent Henry's constant by first focusing on the $H_2S$-$H_2O$ binary system and then considers the effect of adding monoethanolamine (MEA) as a chemical solvent. The computations are performed by a process simulator and due to space limitations, the models are discussed in general terms only.

Figure 4-12 presents the apparent Henry's constant of $H_2S$ in $H_2O$ plotted versus its apparent liquid mole fraction; the data are from Lee and Mather [*Ber. Bunsenges. Phys. Chem.* **81:** 1020 (1977)]. The model uses the Redlich-Kwong equation of state for $\hat{\phi}_i^V$, the electrolyte-NRTL model for $\gamma_i^*$, and the Brelvi-O'Connell correlation [*AIChE J.* **18:** 1239 (1972)] for $\overline{V}_i^\infty$. The model also includes the dissociation of $H_2S$ into ionic species, as described by Eqs. (4-243) and (4-244), where the dissociation constants and their temperature dependence are determined by the methods described by Chen and co-workers in references at the beginning of this subsection, and Henry's law constant is given by Eq. (4-206).

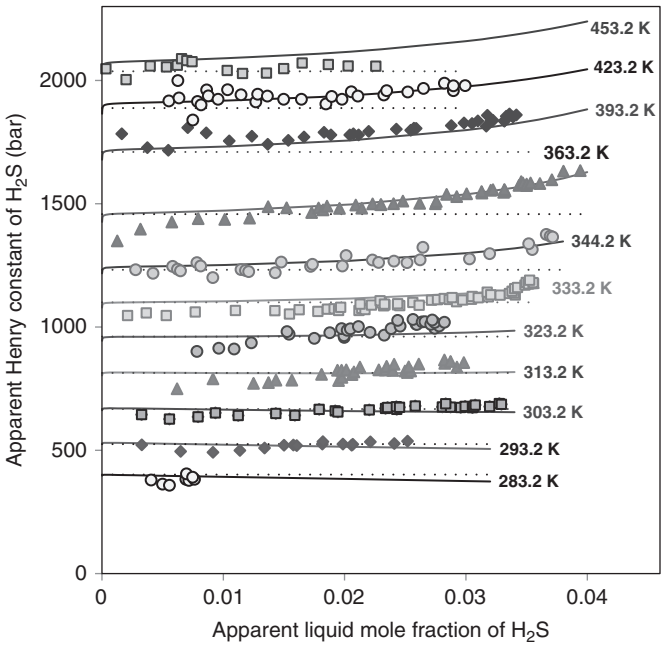

**FIG. 4-12** Apparent Henry constants for $H_2S$ in $H_2O$. The data points are from Lee and Mather [*Ber. Bunsenges. Phys. Chem.* **81:** 1020 (1977)], the solid line is calculated by the model, and the horizontal dashed lines show Henry constants at each temperature.

Figure 4-12 demonstrates that taking $h_{0i}$ as independent of composition in Eq. (4-246) provides a good correlation of the data of Lee and Mather. It is not shown in Fig. 4-12 to avoid cluttering the chart, but note that the model also provides quantitative agreement with the data of Clarke and Glew [*Can. J. Chem.* **49:** 691 (1971)], and Gillespie and Wilson [*Gas. Proc. Assoc.*, RR-48, Tulsa, OK (1982)]. The apparent Henry's constant decreases weakly with increasing $H_2S$ liquid mole fraction at the lowest temperature (283.2 K), and then gradually it has an increasing slope with $H_2S$ composition as the temperature increases. The reason is that both $\gamma_i^*$ and $\hat{\phi}_i^V$ decrease in this particular case as the composition of $H_2S$ increases, and the ratio remains approximately equal to unity. The full calculations show the ratio $x_i/x_{0i}$ is nearly unity at the concentrations of the data due to the p$K_a$ for the first dissociation. Hence the total variation of $h_{0i}$ with $x_{0i}$ at low temperature is largely controlled by the Poynting correction. The Poynting correction increases with pressure, and the pressure increase for a given change in $H_2S$ composition increases with temperature. It may be expected that the use of the complete model will provide better accuracy for general application; however, note that the simple approximation of assuming that the apparent Henry constant is independent of concentration at a given temperature (horizontal dotted lines in Fig. 4-12) is surprisingly accurate in this case, as the errors do not exceed 10 percent.

Close inspection of Fig. 4-12 shows a sharp decrease in the apparent Henry's constant at very low concentrations, and this is so because $H_2S$ dissociates into ions according to Eqs. (4-243) and (4-244). Only the first dissociation is important in the $H_2S + H_2O$ system, and only at very dilute concentrations. For example, at 333.2 K, the fraction of $H_2S$ dissociated into ions when $x_{0i} = 10^{-5}$ is about 2 percent. Hence, the dissociation of $H_2S$ is effectively zero at the measured data points in Fig. 4-12.

Addition of a base dramatically affects the equilibrium because of the large concentration of neutralized ions. Figure 4-13 presents the apparent Henry's constant of $H_2S$ in a 5*N* solution of aqueous MEA (30.2 wt% MEA or an MEA mole fraction of 0.113 in the $H_2S$-free solvent). The curves come from a fitted model. Figure 4-13 is dramatically different from Fig. 4-12 because the values of $h_{0i}$ are smaller by 1 to 5 orders of magnitude, indicating that the apparent solubility at a given partial pressure is correspondingly 1 to 5 orders of magnitude higher. Also, for the MEA mixture, the apparent Henry's constant varies significantly with $H_2S$ composition (note the log scale for $h_{0i}$).

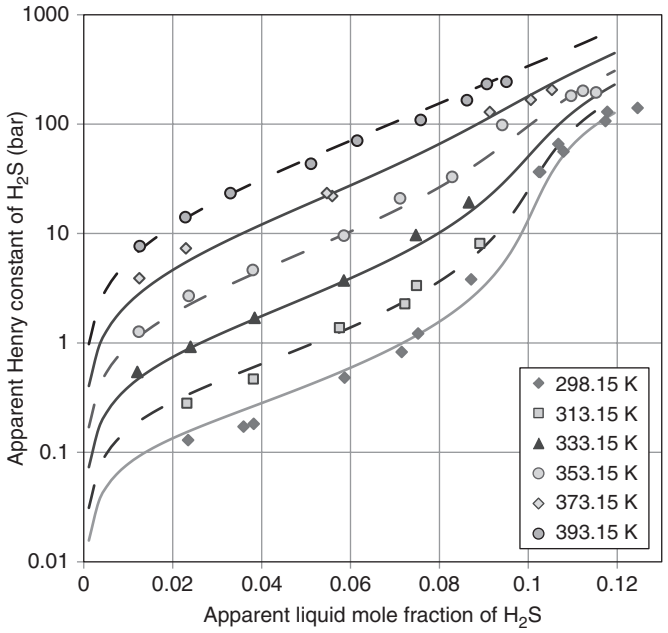

**FIG. 4-13** Apparent Henry constants for $H_2S$ in a 5*N* aqueous solution of monoethanolamine (MEA). The data points are from Lee, Otto, and Mather [*J. Chem. Eng. Data* **21:** 207 (1976)], and the curves are from a model that may be considered to be an interpolation of the data.

An issue that becomes clear when one is faced with the strong variation of the apparent Henry's constant with solute concentration is estimation of the true Henry's constant since the limit of Eq. (4-246) cannot be taken in practice. $CO_2$ is an acid gas similar to $H_2S$, and a chart analogous to Fig. 4-13 may be constructed, for example, using the data of Jou, Mather, and Otto [*Can. J. Chem. Eng.* **73:** 140 (1995)]. Clarke [*Ind. Eng. Chem. Fundam.* **3:** 239 (1964)] suggested $N_2O$ as a *homomorph* for $CO_2$ since the two molecules have similar molecular weights, volumes, and structures, and proposed the "$N_2O$ analogy":

$$\left[\frac{h_{CO_2}}{h_{N_2O}}\right]_{\text{Water}} \approx \left[\frac{h_{CO_2}}{h_{N_2O}}\right]_{\text{Reacting Solution}} \tag{4-247}$$

There is an equivalent equation for the diffusion coefficient. The $N_2O$ analogy has been used in equilibrium and mass-transfer correlations for $CO_2$ in reactive systems, and it has even been tested through molecular modeling by Chen et al. [*Ind. Eng. Chem. Res.* **53:** 18081 (2014)], but there is no equivalent "analogy" for other reactive solutes like $H_2S$. In the case of $H_2S$ it is generally assumed that Henry's constant in water is equal to that in the reacting solution, but it is hoped that better approximations will be invented in the future.

## MODES OF HEAT TRANSFER

Heat is energy transferred due to a difference in temperature. There are three modes of heat transfer: conduction, convection, and radiation. All three may act at the same time. *Conduction* is the transfer of energy between adjacent particles of matter. It is a local phenomenon and can only occur through matter. *Radiation* is the transfer of energy from a point of higher temperature to a point of lower energy by electromagnetic radiation. Radiation can act at a distance through transparent media and vacuum. *Convection* is the transfer of energy by conduction and radiation in moving, fluid media. The motion of the fluid is an essential part of convective heat transfer.

**Nomenclature and Units—Heat Transfer by Conduction, by Convection, and with Phase Change**

| Symbol | Definition | SI units |
|---|---|---|
| $A$ | Area for heat transfer | $m^2$ |
| $A_c$ | Cross-sectional area | $m^2$ |
| $A_f$ | Area for heat transfer for finned portion of surface | $m^2$ |
| $A_1$ | First Fourier coefficient | |
| $b$ | Geometry: $b = 1$, plane; $b = 2$, cylinder; $b = 3$, sphere | |
| $B_1$ | First Fourier coefficient | |
| Bi | Biot number, $hR/k$ | |
| $c$ | Specific heat | J/(kg·K) |
| $c_p$ | Specific heat, constant pressure | J/(kg·K) |
| $D$ | Diameter | m |
| $D_i$ | Inner diameter | m |
| $D_o$ | Outer diameter | m |
| $f$ | Fanning friction factor | |
| Fo | Dimensionless time or Fourier number, $\alpha t/R^2$ | |
| $g$ | Acceleration of gravity, 9.81 $m^2/s$ | $m^2/s$ |
| $G$ | Mass velocity, $\dot{m}/A_c$ | kg/($m^2$·s) |
| Gz | Graetz number = Re Pr | |
| $h$ | Heat-transfer coefficient | W/($m^2$·K) |
| $\overline{h}$ | Average heat-transfer coefficient | W/($m^2$·K) |
| $h_i$ | Heat-transfer coefficient at inside tube surface | W/($m^2$·K) |
| $h_o$ | Heat-transfer coefficient at outside tube surface | W/($m^2$·K) |
| $h_{am}$ | Heat-transfer coefficient for use with $\Delta T_{am}$, see Eq. (5.40) | W/($m^2$·K) |
| $h_{lm}$ | Heat-transfer coefficient for use with $\Delta T_{lm}$; see Eq. (5-39) | W/($m^2$·K) |
| $h_{fg}$ | Enthalpy of vaporization | kJ/kg |
| $k$ | Thermal conductivity | W/(m·K) |
| $\overline{k}$ | Average thermal conductivity | W/(m·K) |
| $L$ | Length of cylinder or length of flat plate in direction of flow or downstream distance | m |
| | Length of heat-transfer surface | m |
| $\dot{m}$ | Mass flow rate | kg/s |
| $Nu_D$ | Nusselt number $hD/k$ based on diameter $D$ | |
| $\overline{Nu}_D$ | Average Nusselt number $\overline{h}\,D/k$ based on diameter $D$ | |
| $p$ | Perimeter | m |
| $P$ | Perimeter of fin | m |
| Pr | Prandtl number, $\nu/\alpha$ | |
| $q$ | Flux of heat | $W/m^2$ |
| $Q$ | Amount of heat transfer | J |
| $\dot{Q}$ | Rate of heat transfer | W |
| $Q/Q_i$ | Heat loss fraction, $Q/[\rho cV(T_i - T_\infty)]$ | |
| $r$ | Distance from center in plate, cylinder, or sphere | m |
| $R$ | Thermal resistance or radius | K/W or m |
| $Ra_x$ | Rayleigh number, $\beta\,\Delta T\,gx^3/\nu\alpha$ | |

| Symbol | Definition | SI units |
|---|---|---|
| $Re_D$ | Reynolds number, $GD/\mu$ | |
| $S$ | Volumetric source term | $W/m^3$ |
| $S_1$ | Fourier spatial function | |
| $t$ | Time | s |
| $T$ | Temperature | K or °C |
| $T_b$ | Bulk or mean temperature at a given $x$ | K |
| $\overline{T}_b$ | Bulk mean temperature, $(T_{b,in} + T_{b,out})/2$ | K |
| $T_C$ | Temperature of cold surface in enclosure | K |
| $T_f$ | Film temperature, $(T_s + T_e)/2$ | K |
| $T_H$ | Temperature of hot surface in enclosure | K |
| $T_i$ | Initial temperature | K |
| $T_e$ | Temperature of free stream | K |
| $T_s$ | Temperature of surface | K |
| $T_{sat}$ | Saturation temperature of vapor | K |
| $T_\infty$ | Temperature of fluid in contact with a solid surface | K |
| $U$ | Overall heat-transfer coefficient | W/($m^2$·K) |
| $V$ | Volume | $m^3$ |
| $V_\infty$ | Velocity upstream of tube bank | m/s |
| $x$ | Cartesian coordinate direction, characteristic dimension of a surface, or distance from entrance | m |
| | **Greek Symbols** | |
| $\alpha$ | Thermal diffusivity, $k/(\rho c)$ | $m^2/s$ |
| $\beta$ | Fin parameter defined by Eq. (5-17) | $m^{-1}$ |
| $\beta$ | Volumetric coefficient of expansion | $K^{-1}$ |
| $\Gamma$ | Mass flow rate per unit length perpendicular to flow | kg/(m·s) |
| $\Delta T$ | Temperature difference | K |
| $\Delta T_{am}$ | Arithmetic mean temperature difference, see Eq. (5-40) | K |
| $\Delta T_{lm}$ | Logarithmic mean temperature difference, see Eq. (5-39) | K |
| $\Delta x$ | Thickness of plane wall for conduction | m |
| $\delta_1$ | First dimensionless eigenvalue | |
| $\delta_{1,0}$ | First dimensionless eigenvalue as Bi approaches 0 | |
| $\delta_{1,\infty}$ | First dimensionless eigenvalue as Bi approaches ∞ | |
| $\varepsilon$ | Emissivity of a surface | |
| $\zeta$ | Dimensionless distance, $r/R$ | |
| $\eta_f$ | Fin efficiency | |
| $\theta/\theta_i$ | Dimensionless temperature, $(T - T_\infty)/(T_i - T_\infty)$ | |
| $\mu$ | Viscosity | kg/(m·s) |
| $\nu$ | Kinematic viscosity, $\mu/\rho$ | $m^2/s$ |
| $\rho$ | Density | $kg/m^3$ |
| $\sigma$ | Stefan-Boltzmann constant, $5.67 \times 10^{-8}$ | W/($m^2$·$K^4$) |
| $\sigma$ | Surface tension between liquid and its vapor | N/m |
| $\tau$ | Time constant, time scale | s |

# HEAT TRANSFER BY CONDUCTION

## FOURIER'S LAW

The heat flux due to conduction in the $x$ direction is given by Fourier's law

$$\dot{Q} = -kA\frac{dT}{dx} \tag{5-1}$$

where $\dot{Q}$ is the rate of heat transfer (W), $k$ is the thermal conductivity [W/(m · K)], $A$ is the area perpendicular to the $x$ direction, and $T$ is temperature (K). For the homogeneous wall shown in Fig. 5-1*a*, with constant $k$, the integrated form of Eq. (5-1) is

$$\dot{Q} = kA\frac{T_1 - T_2}{\Delta x} \tag{5-2}$$

where $\Delta x$ is the thickness of the wall. Using the thermal circuit shown in Fig. 5-1*b*, Eq. (5-2) can be written in the form

$$\dot{Q} = \frac{T_1 - T_2}{\Delta x / kA} = \frac{T_1 - T_2}{R} \tag{5-3}$$

where $R$ is the thermal resistance (K/W).

## THERMAL CONDUCTIVITY

The thermal conductivity $k$ is a transport property whose value for a variety of gases, liquids, and solids is tabulated in Sec. 2. That section also provides methods for predicting and correlating vapor and liquid thermal conductivities. The thermal conductivity is a function of temperature, but the use of constant or averaged values is frequently sufficient. Room temperature values for air, water, concrete, and copper are, respectively, 0.026, 0.61, 1.4, and 400 W/(m · K). Methods for estimating contact resistances and the thermal conductivities of composites and insulation are summarized by Gebhart, *Heat Conduction and Mass Diffusion*, McGraw-Hill, New York, 1993, p. 399.

## STEADY CONDUCTION

**One-Dimensional Conduction** In the absence of energy source terms, $\dot{Q}$ is constant with distance, as shown in Fig. 5-1*a*. For steady conduction, the integrated form of (5-1) for a planar system with constant $k$ and $A$ is Eq. (5-2) or (5-3). For the general case of variables $k$ ($k$ is a function of temperature) and $A$ (cylindrical and spherical systems with radial coordinate $r$, as sketched in Fig. 5-2), the average heat-transfer area and thermal conductivity are defined such that

$$\dot{Q} = \overline{kA}\frac{T_1 - T_2}{\Delta x} = \frac{T_1 - T_2}{R} \tag{5-4}$$

For a thermal conductivity that depends linearly on $T$,

$$k = k_0(1 + \gamma T) \tag{5-5}$$

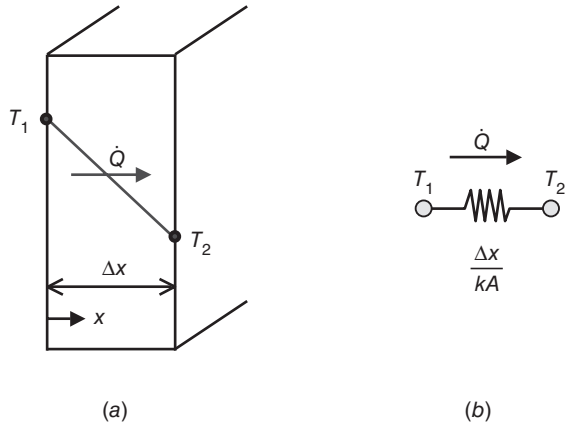

**FIG. 5-1** Steady, one-dimensional conduction in a homogeneous planar wall with constant $k$. The thermal circuit is shown in (*b*) with thermal resistance $\Delta x/(kA)$.

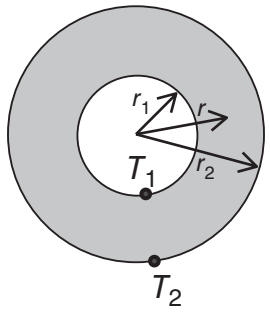

**FIG. 5-2** The hollow sphere or cylinder.

and the average heat thermal conductivity is

$$\overline{k} = k_0(1 + \gamma\overline{T}) \tag{5-6}$$

where $\overline{T} = 0.5(T_1 + T_2)$ and $\gamma$ is a constant.

For cylinders and spheres, $A$ is a function of radial position (see Fig. 5-2): $2\pi rL$ and $4\pi r^2$, where $L$ is the length of the cylinder. For constant $k$, Eq. (5-4) becomes

$$\dot{Q} = \frac{T_1 - T_2}{[\ln(r_2/r_1)]/(2\pi kL)} \qquad \text{cylinder} \tag{5-7}$$

and

$$\dot{Q} = \frac{T_1 - T_2}{(r_2 - r_1)/(4\pi k r_1 r_2)} \qquad \text{sphere} \tag{5-8}$$

**Conduction with Resistances in Series** A steady temperature profile in a planar composite wall, with three constant thermal conductivities and no source terms, is shown in Fig. 5-3*a*. The corresponding thermal circuit is given in Fig. 5-3*b*. The rate of heat transfer through each of the layers is the same. The total resistance is the sum of the individual resistances shown in Fig. 5-3*b*:

$$\dot{Q} = \frac{T_1 - T_2}{\dfrac{\Delta x_A}{k_A A} + \dfrac{\Delta x_B}{k_B A} + \dfrac{\Delta x_C}{k_C A}} = \frac{T_1 - T_2}{R_A + R_B + R_C} \tag{5-9}$$

Additional resistances in the series may occur at the surfaces of the solid if they are in contact with a fluid. The rate of convective heat transfer, between a surface of area $A$ and a fluid, is given by Newton's law of cooling as

$$\dot{Q} = hA(T_{\text{surface}} - T_{\text{fluid}}) = \frac{T_{\text{surface}} - T_{\text{fluid}}}{1/(hA)} \tag{5-10}$$

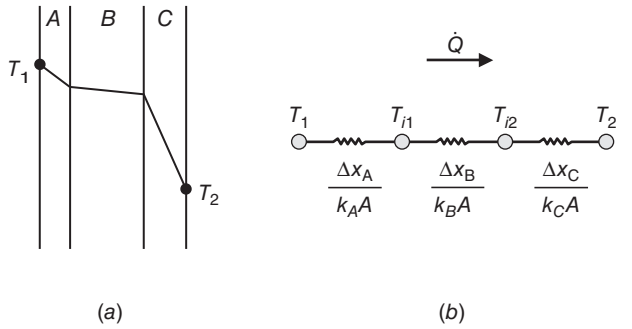

**FIG. 5-3** Steady temperature profile in a composite wall with constant thermal conductivities $k_A$, $k_B$, and $k_C$ and no energy sources in the wall. The thermal circuit is shown in (*b*). The total resistance is the sum of the three resistances shown.

where $1/(hA)$ is the resistance due to convection (K/W) and the heat-transfer coefficient is $h$[W/(m$^2$·K)]. For the cylindrical geometry shown in Fig. 5-2, with convection to inner and outer fluids at temperatures $T_i$ and $T_o$, with heat-transfer coefficients $h_i$ and $h_o$, the steady rate of heat transfer is

$$\dot{Q} = \frac{T_i - T_o}{\dfrac{1}{2\pi r_1 L h_i} + \dfrac{\ln(r_2/r_1)}{2\pi k L} + \dfrac{1}{2\pi r_2 L h_o}} = \frac{T_i - T_o}{R_i + R_1 + R_o} \tag{5-11}$$

where resistances $R_i$ and $R_o$ are the convective resistances at the inner and outer surfaces. The total resistance is again the sum of the resistances in series.

***Example 5-1 Conduction with Resistances in Series and Parallel*** Figure 5-4 shows the thermal circuit for a furnace wall. The outside surface has a known temperature $T_2 = 625$ K. The temperature of the surroundings $T_{sur}$ is 290 K. We want to estimate the temperature of the inside surface $T_1$. The wall consists of three layers: deposit [$k_D = 1.6$ W/(m·K), $\Delta x_D = 0.080$ m], brick [$k_B = 1.7$ W/(m·K), $\Delta x_B = 0.15$ m], and steel [$k_S = 45$ W/(m·K), $\Delta x_S = 0.00245$ m]. The outside surface loses heat by two parallel mechanisms—convection and radiation. The convective heat transfer coefficient $h_C = 5.0$ W/(m$^2$·K). The radiative heat-transfer coefficient $h_R = 16.3$ W/(m$^2$·K). The latter is calculated from

$$h_R = \varepsilon_2 \sigma (T_2^2 + T_{sur}^2)(T_2 + T_{sur}) \tag{5-12}$$

where the emissivity of surface 2 is $\varepsilon_2 = 0.76$ and the Stefan-Boltzmann constant $\sigma = 5.67 \times 10^{-8}$ W/(m$^2$·K$^4$).

Referring to Fig. 5-4, the steady heat flux $q$ (W/m$^2$) through the wall is

$$q = \frac{\dot{Q}}{A} = \frac{T_1 - T_2}{\dfrac{\Delta x_D}{k_D} + \dfrac{\Delta x_B}{k_B} + \dfrac{\Delta x_S}{k_S}} = (h_C + h_R)(T_2 - T_{sur})$$

Solving for $T_1$ gives

$$T_1 = T_2 + \left( \frac{\Delta x_D}{k_D} + \frac{\Delta x_B}{k_B} + \frac{\Delta x_S}{k_S} \right)(h_C + h_R)(T_2 - T_{sur})$$

and

$$T_1 = 625 + \left( \frac{0.080}{1.6} + \frac{0.15}{1.7} + \frac{0.00254}{45} \right)(5.0 + 16.3)(625 - 290) = 1610 \text{ K}$$

**Conduction with Heat Source** Application of the law of conservation of energy to a one-dimensional solid, with the heat flux given by Eq. (5-1) and volumetric source term $S$ (W/m$^3$), results in the following equations for steady conduction in a flat plate of thickness $2R$ ($b = 1$), a cylinder of diameter $2R$ ($b = 2$), and a sphere of diameter $2R$ ($b = 3$). The parameter $b$ is a measure of the curvature. The thermal conductivity is constant, and there is convection at the surface, with heat-transfer coefficient $h$ and fluid temperature $T_\infty$.

$$\frac{d}{dr}\left( r^{b-1} \frac{dT}{dr} \right) + \frac{S}{k} r^{b-1} = 0$$

$$\frac{dT(0)}{dr} = 0 \qquad \text{(symmetry condition)} \tag{5-13}$$

$$-k \frac{dT}{dr} = h[T(R) - T_\infty]$$

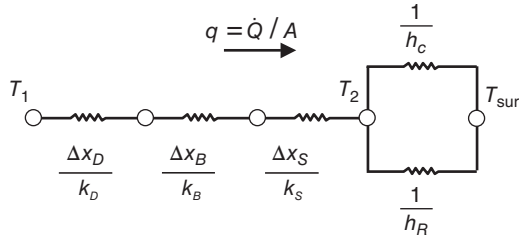

**FIG. 5-4** Thermal circuit for Example 5-1. Steady conduction in a furnace wall with heat losses from the outside surface by convection ($h_C$) and radiation ($h_R$) to the surroundings at temperature $T_{sur}$. The thermal conductivities $k_D$, $k_B$, and $k_S$ are constant. The heat flux $q$ has units of W/m$^2$.

The solutions to Eq. (5-13), for uniform $S$, are

$$\frac{T(r) - T_\infty}{SR^2/k} = \frac{1}{2b}\left[ 1 - \left( \frac{r}{R} \right)^2 \right] + \frac{1}{b\text{Bi}} \qquad \begin{cases} b = 1, \text{ plate, thickness } 2R \\ b = 2, \text{ cylinder, diameter } 2R \\ b = 3, \text{ sphere, diameter } 2R \end{cases} \tag{5-14}$$

where Bi $= hR/k$ is the Biot number. For Bi << 1, the temperature in the solid is uniform. For Bi >> 1, the surface temperature $T(R) = T_\infty$.

**Two- and Three-Dimensional Conduction** Application of the law of conservation of energy to a three-dimensional solid, with the heat flux given by Eq. (5-1) and volumetric source term $S$ (W/m$^3$), results in the following equation for steady conduction in rectangular coordinates.

$$\frac{\partial}{\partial x}\left( k \frac{\partial T}{\partial x} \right) + \frac{\partial}{\partial y}\left( k \frac{\partial T}{\partial y} \right) + \frac{\partial}{\partial z}\left( k \frac{\partial T}{\partial z} \right) + S = 0 \tag{5-15}$$

Similar equations apply to cylindrical and spherical coordinate systems. Finite difference, finite volume, or finite element methods are generally necessary to solve Eq. (5-15). Useful introductions to these numerical techniques are given in General References and Sec. 3. Simple forms of Eq. (5-15) (constant $k$, uniform $S$) can be solved analytically. See Arpaci, *Conduction Heat Transfer*, Addison-Wesley, Boston, 1966, p. 180, and Carslaw and Jaeger, *Conduction of Heat in Solids*, Oxford University Press, London, 1959. For problems involving heat flow between two surfaces, each isothermal, with all other surfaces being adiabatic, the shape factor approach is useful (Mills, *Heat Transfer*, 2d ed., Prentice-Hall, Upper Saddle River, N.J., 1999, p. 164).

**Fins** The rate of heat transfer from a surface can be increased by adding fins to increase its area (Mills, *Heat Transfer*, 2nd ed., Prentice-Hall, Upper Saddle River, N.J., 1999, p. 86). Adding fins increases the area, but not the entire added surface is at the temperature of the original surface and it becomes necessary to calculate the efficiency of the fin as follows.

The governing equation and boundary conditions for a pin fin are

$$kA_c \frac{d^2T}{dx^2} - hP(T - T_\infty) = 0$$

$$T\big|_{x=0} = T_B \tag{5-16}$$

$$\left.\frac{dT}{dx}\right|_{x=L} = 0$$

where the cross-sectional area of the fin $A_c$ is constant and heat loss from the tip of the fin is assumed negligible. The temperature distribution, heat loss, and fin efficiency with these assumptions are

$$\frac{T - T_\infty}{T_B - T_\infty} = \frac{\cosh\beta(L - x)}{\cosh\beta L} \qquad \text{where} \qquad \beta = \left( \frac{hP}{kA_c} \right)^{1/2} \tag{5-17}$$

$$\dot{Q} = kA_c\beta(T_B - T_\infty)\tanh\beta L \tag{5-18}$$

$$\eta_f = \frac{\tanh\beta L}{\beta L} \tag{5-19}$$

For a surface that is covered with fins of efficiency $\eta_f$, the total surface efficiency is given by

$$A\eta_t = (A - A_f) + \eta_f A_f \tag{5-20}$$

where $A$ is the total area for heat transfer and $A_f$ is the surface area of the fins. The total efficiency becomes

$$\eta_t = 1 - \frac{A_f}{A}(1 - \eta_f) \tag{5-21}$$

The thermal resistance, based on the total area for heat transfer, becomes

$$R = \frac{1}{h_c A \eta_t} \tag{5-22}$$

Mills (*Heat Transfer*, 2d ed., Prentice-Hall, Upper Saddle River, N.J., 1999, p. 104) provides fin efficiencies for a variety of fin shapes.

## UNSTEADY CONDUCTION

Application of the law of conservation of energy to a three-dimensional solid, with the heat flux given by Eq. (5-1) and volumetric source term

$S$ (W/m$^3$), results in the following equation for unsteady conduction in rectangular coordinates.

$$\rho c\frac{\partial T}{\partial t}=\frac{\partial}{\partial x}\left(k\frac{\partial T}{\partial x}\right)+\frac{\partial}{\partial y}\left(k\frac{\partial T}{\partial y}\right)+\frac{\partial}{\partial z}\left(k\frac{\partial T}{\partial z}\right)+S \tag{5-23}$$

The energy storage term is on the left-hand side, and ρ and $c$ are, respectively, the density (kg/m$^3$) and specific heat [J/(kg·K)]. Solutions to Eq. (5-23) are generally obtained numerically (see General References and Sec. 3). The one-dimensional form of Eq. (5-23), with constant $k$ and no source term, is

$$\frac{\partial T}{\partial t}=\alpha\frac{\partial^2 T}{\partial x^2} \tag{5-24}$$

where $\alpha = k/(\rho c)$ is the thermal diffusivity (m$^2$/s).

**One-Dimensional Conduction: Lumped and Distributed Analysis** The one-dimensional transient conduction equations in rectangular ($b = 1$), cylindrical ($b = 2$), and spherical ($b = 3$) coordinates, with constant $k$, initial uniform temperature $T_i$, $S = 0$, and convection at the surface with heat-transfer coefficient $h$ and fluid temperature $T_\infty$, are

$$\frac{\partial T}{\partial t}=\frac{\alpha}{r^{b-1}}\frac{\partial}{\partial r}\left(r^{b-1}\frac{\partial T}{\partial r}\right)\quad\begin{cases} b=1,\text{ plate, thickness } 2R\\ b=2,\text{ cylinder, diameter } 2R\\ b=3,\text{ sphere, diameter } 2R\end{cases}$$

$$\text{For } t<0,\qquad T=T_i\qquad\text{(initial temperature)} \tag{5-25}$$

$$\text{At } r=0,\qquad \frac{\partial T}{\partial r}=0\qquad\text{(symmetry condition)}$$

$$\text{At } r=R,\qquad -k\frac{\partial T}{\partial r}=h(T-T_\infty)$$

The solutions to Eq. (5-25) can be compactly expressed by using dimensionless variables: (1) temperature $\theta/\theta_i = [T(r, t) - T_\infty]/(T_i - T_\infty)$; (2) heat loss fraction $Q/Q_i = Q/[\rho cV(T_i - T_\infty)]$, where $V$ is volume; (3) distance from center $\zeta = r/R$; (4) time $\text{Fo} = \alpha t/R^2$; and (5) Biot number $\text{Bi} = hR/k$. The temperature and heat loss are functions of ζ, Fo, and Bi.

When the Biot number is small, Bi < 0.1, the temperature of the solid is nearly uniform and a lumped analysis is acceptable. The solution to the lumped analysis of Eq. (5-25) is

$$\frac{\theta}{\theta_i}=\exp\left(-\frac{hA}{\rho cV}t\right)\quad\text{and}\quad\frac{Q}{Q_i}=1-\exp\left(-\frac{hA}{\rho cV}t\right) \tag{5-26}$$

where $A$ is the active surface area and $V$ is the volume. The time scale for the lumped problem is

$$\tau=\frac{\rho cV}{hA} \tag{5-27}$$

The time scale is the time required for most of the change in $Q/Q_i$ or $\theta/\theta_i$ to occur. When $t = \tau$, $\theta/\theta_i = \exp(-1) = 0.368$ and roughly two-thirds of the possible change has occurred.

When a lumped analysis is not valid (Bi > 0.1), the single-term solutions to Eq. (5-25) are convenient:

$$\frac{\theta}{\theta_i}=A_1\exp(-\delta_1^2\text{Fo})S_1(\delta_1\zeta)\quad\text{and}\quad\frac{Q}{Q_i}=1-B_1\exp(-\delta_1^2\text{Fo}) \tag{5-28}$$

where the first Fourier coefficients $A_1$ and $B_1$ and the spatial functions $S_1$ are given in Table 5-1. The first eigenvalue $\delta_1$ is given by Eq. (5-29) in conjunction with Table 5-2. The one-term solutions are accurate to within 2 percent when $\text{Fo} > \text{Fo}_c$. The values of the critical Fourier number $\text{Fo}_c$ are given in Table 5-2.

**TABLE 5-1 Fourier Coefficients and Spatial Functions for Use in Eq. (5-28)**

| Geometry | $A_1$ | $B_1$ | $S_1$ |
|---|---|---|---|
| Plate | $\dfrac{2\sin\delta_1}{\delta_1+\sin\delta_1\cos\delta_1}$ | $\dfrac{2\text{Bi}^2}{\delta_1^2(\text{Bi}^2+\text{Bi}+\delta_1^2)}$ | $\cos(\delta_1\zeta)$ |
| Cylinder | $\dfrac{2J_1(\delta_1)}{\delta_1[J_0^2(\delta_1)+J_1^2(\delta_1)]}$ | $\dfrac{4\text{Bi}^2}{\delta_1^2(\delta_1^2+\text{Bi}^2)}$ | $J_0(\delta_1\zeta)$ |
| Sphere | $\dfrac{2\text{Bi}[\delta_1^2+(\text{Bi}-1)^2]^{1/2}}{(\delta_1^2+\text{Bi}^2-\text{Bi})}$ | $\dfrac{6\text{Bi}^2}{\delta_1^2(\delta_1^2+\text{Bi}^2-\text{Bi})}$ | $\dfrac{\sin(\delta_1\zeta)}{\delta_1\zeta}$ |

**TABLE 5-2 First Eigenvalues for Bi → 0, Bi → ∞, Correlation Parameter $n$, where the Single-Term Approximations Apply Only If Fo ≥ $\text{Fo}_c$**

| Geometry | Bi → 0 | Bi → ∞ | $n$ | $\text{Fo}_c$ |
|---|---|---|---|---|
| Plate | $\delta_1\to\sqrt{\text{Bi}}$ | $\delta_1\to\pi/2$ | 2.139 | 0.24 |
| Cylinder | $\delta_1\to\sqrt{2\text{Bi}}$ | $\delta_1\to 2.4048255$ | 2.238 | 0.21 |
| Sphere | $\delta_1\to\sqrt{3\text{Bi}}$ | $\delta_1\to\pi$ | 2.314 | 0.18 |

The first eigenvalue is accurately correlated by Yovanovich (Chap. 3 of Rohsenow, Hartnett, and Cho, *Handbook of Heat Transfer*, 3d ed., McGraw-Hill, New York, 1998, p. 3.25)

$$\delta_1=\frac{\delta_{1,\infty}}{\left[1+(\delta_{1,\infty}/\delta_{1,0})^n\right]^{1/n}} \tag{5-29}$$

Equation (5-29) gives values of $\delta_1$ that differ from the exact values by less than 0.4 percent, and it is valid for all values of Bi. The values of $\delta_{1,\infty}$, $\delta_{1,0}$, $n$, and $\text{Fo}_c$ are given in Table 5-2.

***Example 5-2 Correlation of First Eigenvalues by Eq. (5-29)*** As an example of the use of Eq. (5-29), suppose that we want $\delta_1$ for the flat plate with Bi = 5. From Table 5-2, $\delta_{1,\infty} = \pi/2$, $\delta_{1,0} = \sqrt{\text{Bi}} = \sqrt{5}$, and $n = 2.139$. Equation (5-29) gives

$$\delta_1=\frac{\pi/2}{\left[1+\{(\pi/2)/(\sqrt{5})\}^{2.139}\right]^{1/2.139}}=1.312$$

The tabulated value is 1.3138.

***Example 5-3 One-Dimensional, Unsteady Conduction Calculation*** As an example of the use of Eq. (5-28), Table 5-1, and Table 5-2, consider the cooking time required to raise the center of a spherical, 8-cm-diameter dumpling from 20 to 80°C. The initial temperature is uniform. The dumpling is heated with saturated steam at 95°C. The heat capacity, density, and thermal conductivity are estimated to be $c = 3500$ J/(kg·K), $\rho = 1000$ kg/m$^3$, and $k = 0.5$ W/(m·K), respectively.

Because the heat-transfer coefficient for condensing steam is of order $10^4$, the Bi → ∞ limit in Table 5-2 is a good choice and $\delta_1 = \pi$. Because we know the desired temperature at the center, we can calculate $\theta/\theta_i$ and then solve Eq. (5-28) for the time.

$$\frac{\theta}{\theta_i}=\frac{T(0,t)-T_\infty}{T_i-T_\infty}=\frac{80-95}{20-95}=0.200$$

For Bi → ∞, $A_1$ in Table 5-1 is 2 and for $\zeta = 0$, $S_1$ in Table 5-1 is 1. Equation (5-28) becomes

$$\frac{\theta}{\theta_i}=2\exp(-\pi^2\text{Fo})=2\exp\left(-\pi^2\frac{\alpha t}{R^2}\right)$$

Solving for $t$ gives the desired cooking time.

$$t=-\frac{R^2}{\alpha\pi^2}\ln\frac{\theta}{2\theta_i}=-\frac{(0.04\text{ m})^2}{1.43\times10^{-7}(\text{m}^2/\text{s})\pi^2}\ln\frac{0.2}{2}=43.5\text{ min}$$

The one-term approximation is applicable in this case because calculation of Fo gives 0.23, which is greater than $\text{Fo}_c = 0.18$ from Table 5-2.

***Example 5-4 Rule of Thumb for Time Required to Diffuse a Distance R*** A general rule of thumb for estimating the time required to diffuse a distance $R$ is obtained from the one-term approximations. Consider the equation for the temperature of a flat plate of thickness $2R$ in the limit as Bi → ∞. From Table 5-2, the first eigenvalue is $\delta_1 = \pi/2$, and from Table 5-1,

$$\frac{\theta}{\theta_i}=A_1\exp\left[-\left(\frac{\pi}{2}\right)^2\frac{\alpha t}{R^2}\right]\cos\delta_1\zeta$$

When $t = R^2/\alpha$, the temperature ratio at the center of the plate ($\zeta = 0$) has decayed to $\exp(-\pi^2/4)$, or 8 percent of its initial value. We conclude that *diffusion through*

*a distance R takes roughly* $R^2/\alpha$ *units of time,* or alternatively, *the distance diffused in time t is about* $(\alpha t)^{1/2}$. More generally, the time scale for Eq. (5-25) for any Bi is approximately

$$\tau \approx \frac{R^2}{b\alpha}\left(\frac{1}{2}+\frac{1}{\text{Bi}}\right)$$

**One-Dimensional Conduction: Semi-infinite Plate** Consider a semi-infinite plate with an initial uniform temperature $T_i$. Suppose that the temperature of the surface is suddenly raised to $T_\infty$; that is, the heat-transfer coefficient is infinite. The unsteady temperature of the plate is

$$\frac{T(x,t)-T_\infty}{T_i-T_\infty} = \text{erf}\left(\frac{x}{2\sqrt{\alpha t}}\right) \tag{5-30}$$

where erf($z$) is the error function. The depth to which the heat penetrates in time $t$ is approximately $(12\alpha t)^{1/2}$.

If the heat-transfer coefficient is finite,

$$\frac{T(x,t)-T_\infty}{T_i-T_\infty} = \text{erf}\left(\frac{x}{2\sqrt{\alpha t}}\right)+\exp\left(\frac{hx}{k}+\frac{h^2\alpha t}{k^2}\right)\text{erfc}\left(\frac{x}{2\sqrt{\alpha t}}+\frac{h\sqrt{\alpha t}}{k}\right) \tag{5-31}$$

Equations (5-30) and (5-31) are applicable to finite plates provided that their half-thickness is greater than $(12\alpha t)^{1/2}$.

**Two- and Three-Dimensional Conduction** The one-dimensional solutions discussed above can be used to construct solutions to multidimensional problems. The unsteady temperature of a rectangular, solid box of height, length, and width $2H$, $2L$, and $2W$, respectively, with governing equations in each direction as in Eq. (5-25), is

$$\left(\frac{\theta}{\theta_i}\right)_{2H\times 2L\times 2W} = \left(\frac{\theta}{\theta_i}\right)_{2H}\left(\frac{\theta}{\theta_i}\right)_{2L}\left(\frac{\theta}{\theta_i}\right)_{2W} \tag{5-32}$$

Similar products apply for solids with other geometries, e.g., semi-infinite, cylindrical rods.

# HEAT TRANSFER BY CONVECTION

## CONVECTIVE HEAT-TRANSFER COEFFICIENT

Convection is the transfer of energy by conduction and radiation in moving, fluid media. The motion of the fluid is an essential part of convective heat transfer. A key step in calculating the rate of heat transfer by convection is the calculation of the heat-transfer coefficient. This section focuses on the estimation of heat-transfer coefficients for natural and forced convection. The conservation equations for mass, momentum, and energy, as presented in Sec. 6, can be used to calculate the rate of convective heat transfer. Our approach in this section is to rely on correlations.

In many cases of industrial importance, heat is transferred from one fluid, through a solid wall, to another fluid. The transfer occurs in a heat exchanger. Section 11 introduces several types of heat exchangers, design procedures, overall heat-transfer coefficients, and mean temperature differences. Section 3 introduces dimensional analysis and the dimensionless groups associated with the heat-transfer coefficient.

**Individual Heat-Transfer Coefficient** The local rate of convective heat transfer between a surface and a fluid is given by Newton's law of cooling

$$q = h(T_{\text{surface}} - T_{\text{fluid}}) \tag{5-33}$$

where $h$ [W/(m$^2\cdot$K)] is the local heat-transfer coefficient and $q$ is the energy flux (W/m$^2$). The definition of $h$ is arbitrary, depending on whether the bulk fluid, centerline, free stream, or some other temperature is used for $T_{\text{fluid}}$. The heat-transfer coefficient may be defined on an average basis as noted below.

Consider a fluid with bulk temperature $T$, flowing in a cylindrical tube of diameter $D$, with constant wall temperature $T_s$. An energy balance on a short section of the tube yields

$$c_p \dot{m}\frac{dT}{dx} = \pi D h(T_s - T) \tag{5-34}$$

where $c_p$ is the specific heat at constant pressure [J/(kg$\cdot$K)], $\dot{m}$ is the mass flow rate (kg/s), and $x$ is the distance from the inlet. If the temperature of the fluid at the inlet is $T_{\text{in}}$, the temperature of the fluid at a downstream distance $L$ is

$$\frac{T(L)-T_s}{T_{\text{in}}-T_s} = \exp\left(-\frac{\bar{h}\pi DL}{\dot{m}c_p}\right) \tag{5-35}$$

The average heat-transfer coefficient $\bar{h}$ is defined by

$$\bar{h} = \frac{1}{L}\int_0^L h\,dx \tag{5-36}$$

**Overall Heat-Transfer Coefficient and Heat Exchangers** A local, overall heat-transfer coefficient $U$ for the cylindrical geometry shown in Fig. 5-2 is defined by using Eq. (5-11):

$$\frac{\dot{Q}}{\Delta x} = \frac{T_i - T_o}{\dfrac{1}{2\pi r_1 h_i}+\dfrac{\ln(r_2/r_1)}{2\pi k}+\dfrac{1}{2\pi r_2 h_o}} = 2\pi r_2 U(T_i - T_o) \tag{5-37}$$

where $\Delta x$ is a short length of tube in the axial direction. Equation (5-37) defines $U$ by using the outside perimeter $2\pi r_2$. The inner perimeter can also be used. Equation (5-37) applies to clean tubes. Additional resistances are present in the denominator for dirty tubes (see Sec. 11).

For counterflow and parallel flow heat exchanges, with high- and low-temperature fluids ($T_H$ and $T_C$) and flow directions as defined in Fig. 5-5, the total heat transfer for the exchanger is given by

$$\dot{Q} = UA\,\Delta T_{\text{lm}} \tag{5-38}$$

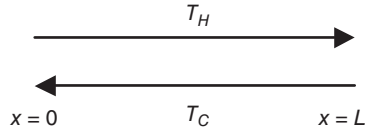
where $A$ is the area for heat exchange and the log mean temperature difference $\Delta T_{\text{lm}}$ is defined as

$$\Delta T_{\text{lm}} = \frac{(T_H - T_C)_{x=0} - (T_H - T_C)_{x=L}}{\ln\left[(T_H - T_C)_{x=0}/(T_H - T_C)_{x=L}\right]} \tag{5-39}$$

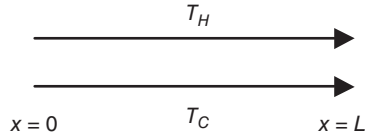
Equation (5-39) applies to both counterflow and parallel-flow exchangers with the nomenclature defined in Fig. 5-5. Correction factors to $\Delta T_{\text{lm}}$ for various heat exchanger configurations are given in Sec. 11.

In certain applications, the log mean temperature difference is replaced with an arithmetic mean difference:

$$\Delta T_{\text{am}} = \frac{(T_H - T_C)_{x=L} + (T_H - T_C)_{x=0}}{2} \tag{5-40}$$



(*a*) Counterflow.



(*b*) Parallel flow.

**FIG. 5-5** Nomenclature for counterflow and parallel-flow heat exchangers for use with Eqs. (5-38) and (5-39).

Average heat-transfer coefficients are occasionally reported based on Eqs. (5-39) and (5-40) and are written as $h_{lm}$ and $h_{am}$.

**Representation of Heat-Transfer Coefficients** Heat-transfer coefficients are usually expressed in two ways: (1) dimensionless equations and (2) dimensional equations. Only the dimensionless approach is used here. The dimensionless form of the heat-transfer coefficient is the Nusselt number. For example, with a cylinder of diameter $D$ in cross flow, the local Nusselt number is defined as $\mathrm{Nu}_D = hD/k$, where $k$ is the thermal conductivity of the fluid. The subscript $D$ is important because different characteristic lengths can be used to define Nu. The average Nusselt number is written $\overline{\mathrm{Nu}}_D = \bar{h}D/k$.

## NATURAL CONVECTION

Natural convection occurs when a fluid is in contact with a solid surface and their temperatures differ. Temperature differences create the density gradients that drive natural or free convection. In addition to the Nusselt number mentioned above, the key dimensionless parameters for natural convection include the Rayleigh number $\mathrm{Ra}_x = \beta \Delta T g x^3/\nu\alpha$ and the Prandtl number $\mathrm{Pr} = \nu/\alpha$. The properties appearing in Ra and Pr include the volumetric coefficient of expansion $\beta$ ($K^{-1}$); the difference $\Delta T$ between the surface ($T_s$) and free stream ($T_e$) temperatures (K or °C); the acceleration of gravity $g$ ($m/s^2$); a characteristic dimension $x$ of the surface (m); the kinematic viscosity $\nu$ ($m^2/s$); and the thermal diffusivity $\alpha$ ($m^2/s$). The volumetric coefficient of expansion for an ideal gas is $\beta = 1/T$, where $T$ is absolute temperature. For a given geometry,

$$\overline{\mathrm{Nu}}_x = f(\mathrm{Ra}_x, \mathrm{Pr}) \tag{5-41}$$

**External Natural Flow for Various Geometries** For vertical walls, Churchill and Chu [*Int. J. Heat Mass Transfer*, **18:** 1323 (1975)] recommend, for laminar and turbulent flow on isothermal, vertical walls with height $L$,

$$\overline{\mathrm{Nu}}_L = \left\{ 0.825 + \frac{0.387\mathrm{Ra}_L^{1/6}}{[1+(0.492/\mathrm{Pr})^{9/16}]^{8/27}} \right\}^2 \tag{5-42}$$

where the fluid properties for Eq. (5-42) and $\overline{\mathrm{Nu}}_L = \bar{h}L/k$ are evaluated at the film temperature $T_f = (T_s + T_e)/2$. This correlation is valid for all Pr and $\mathrm{Ra}_L$. For vertical cylinders with boundary layer thickness much less than their diameter, Eq. (5-42) is applicable. An expression for uniform heating is available from the same reference.

For laminar and turbulent flow on isothermal, horizontal cylinders of diameter $D$, Churchill and Chu [*Int. J. Heat Mass Transfer*, **18:** 1049 (1975)] recommend

$$\overline{\mathrm{Nu}}_L = \left\{ 0.60 + \frac{0.387\mathrm{Ra}_D^{1/6}}{[1+(0.559/\mathrm{Pr})^{9/16}]^{8/27}} \right\}^2 \tag{5-43}$$

Fluid properties for Eq. (5-43) should be evaluated at the film temperature $T_f = (T_s + T_e)/2$. This correlation is valid for all Pr and $\mathrm{Ra}_D$.

For long, horizontal, flat plates, the characteristic dimension for the correlations is the width $L$. With constant surface temperature and hot surfaces facing upward, or cold surfaces facing downward, Lloyd and Moran recommend [ASME Paper 74-WA/HT-66 (1974)]

$$\overline{\mathrm{Nu}}_L = 0.54\mathrm{Ra}_L^{1/4} \quad \text{(laminar)} \quad 10^5 < \mathrm{Ra}_L < 10^7 \tag{5-44}$$

$$\overline{\mathrm{Nu}}_L = 0.15\mathrm{Ra}_L^{1/3} \quad \text{(turbulent)} \quad 10^7 < \mathrm{Ra}_L < 10^9 \tag{5-45}$$

and for hot surfaces facing downward, or cold surfaces facing upward, for laminar and turbulent flow,

$$\overline{\mathrm{Nu}}_L = 0.27\mathrm{Ra}_L^{1/4} \qquad 10^5 < \mathrm{Ra}_L < 10^{10} \tag{5-46}$$

Fluid properties for Eqs. (5-44) to (5-46) should be evaluated at the film temperature,

$$T_f = (T_s + T_e)/2 \tag{5-47}$$

**Simultaneous Heat Transfer by Radiation and Convection** Simultaneous heat transfer by radiation and convection is treated per the procedure outlined in Examples 5-1 and 5-5. A radiative heat-transfer coefficient $h_R$ is defined by Eq. (5-12).

**Mixed Forced and Natural Convection** Natural convection is commonly assisted or opposed by forced flow. These situations are discussed, e.g., by Mills [*Heat Transfer*, 2d ed., Prentice Hall, Upper Saddle River, N.J., 1999, p. 340] and Raithby and Hollands [Chap. 4 of Rohsenow, Hartnett, and Cho, *Handbook of Heat Transfer*, 3d ed., McGraw-Hill, New York, 1998, p. 4.73].

**Enclosed Spaces** The rate of heat transfer across an enclosed space is described in terms of a heat-transfer coefficient based on the temperature difference between two surfaces:

$$\bar{h} = \frac{\dot{Q}/A}{T_H - T_C} \tag{5-48}$$

For rectangular cavities, the plate spacing between the two surfaces $L$ is the characteristic dimension that defines the Nusselt and Rayleigh numbers. The temperature difference in the Rayleigh number $\mathrm{Ra}_L = \beta \Delta T g L^3/\nu\alpha$ is $\Delta T = T_H - T_C$.

For a horizontal rectangular cavity heated from below, the onset of advection requires $\mathrm{Ra}_L > 1708$. Globe and Dropkin [*J. Heat Transfer*, **81:** 24–28 (1959)] propose the correlation

$$\overline{\mathrm{Nu}}_L = 0.069\mathrm{Ra}_L^{1/3}\,\mathrm{Pr}^{0.074} \qquad 3\times10^5 < \mathrm{Ra}_L < 7\times10^9 \tag{5-49}$$

All properties in Eq. (5-49) are calculated at the average temperature $(T_H + T_C)/2$.

For vertical rectangular cavities of height $H$ and spacing $L$, with $\mathrm{Pr} \approx 0.7$ (gases) and $40 < H/L < 110$, the equation of Shewen et al. [*J. Heat Transfer*, **118:** 993–995 (1996)] is recommended:

$$\overline{\mathrm{Nu}}_L = \left\{ 1 + \left[ \frac{0.0665\mathrm{Ra}_L^{1/3}}{1+(9000/\mathrm{Ra}_L)^{1.4}} \right]^2 \right\}^{1/2} \qquad \mathrm{Ra}_L < 10^6 \tag{5-50}$$

All properties in Eq. (5-50) are calculated at the average temperature $(T_H + T_C)/2$.

***Example 5-5 Comparison of the Relative Importance of Natural Convection and Radiation at Room Temperature*** Estimate the heat losses by natural convection and radiation for an undraped person standing in still air. The temperatures of the air, surrounding surfaces, and skin are 19, 15, and 35°C, respectively. The height and surface area of the person are, respectively, 1.8 m and 1.8 $m^2$. The emissivity of the skin is 0.95.

We can estimate the Nusselt number by using Eq. (5-42) for a vertical, flat plate of height $L$ = 1.8 m. The film temperature is (19 + 35)/2 = 27°C. The Rayleigh number, evaluated at the film temperature, is

$$\mathrm{Ra}_L = \frac{\beta \Delta T g L^3}{\nu\alpha} = \frac{(1/300)(35-19)9.81(1.8)^3}{1.589\times10^{-5}(2.25\times10^{-5})} = 8.53\times10^9$$

From Eq. (5-42) with Pr = 0.707, the Nusselt number is 240 and the average heat-transfer coefficient due to natural convection is

$$\bar{h} = \frac{k}{L}\overline{\mathrm{Nu}}_L = \frac{0.0263}{1.8}(240) = 3.50\,\frac{\mathrm{W}}{\mathrm{m}^2\cdot\mathrm{K}}$$

The radiative heat-transfer coefficient is given by Eq. (5-12):

$$h_R = \varepsilon_{skin}\sigma(T_{skin}^2 + T_{sur}^2)(T_{skin} + T_{sur})$$
$$= 0.95(5.67\times10^{-8})(308^2 + 288^2)(308 + 288) = 5.71\,\frac{\mathrm{W}}{\mathrm{m}^2\cdot\mathrm{K}}$$

The total rate of heat loss is

$$\dot{Q} = \bar{h}A(T_{skin} - T_{air}) + \bar{h}_R A(T_{skin} - T_{sur})$$
$$= 3.50(1.8)(35-19) + 5.71(1.8)(35-15) = 306\ \mathrm{W}$$

At these conditions, radiation is nearly twice as important as natural convection.

## FORCED CONVECTION

Forced convection heat transfer is probably the most common mode in the process industries. Forced flows may be internal or external. This subsection briefly introduces correlations for estimating heat-transfer coefficients for flows in tubes and ducts; flows across plates, cylinders, and spheres; flows through tube banks; and heat transfer to nonevaporating falling films.

Section 11 introduces several types of heat exchangers, design procedures, overall heat-transfer coefficients, and mean temperature differences.

**Flow in Round Tubes** In addition to the Nusselt ($Nu_D = hD/k$) and Prandtl ($Pr = \nu/\alpha$) numbers introduced above, the key dimensionless parameter for forced convection in round tubes of inside diameter $D$ is the Reynolds number $Re_D = 4\dot{m}/\pi D\mu = \rho VD/\mu$. For internal flow in a tube or duct, the heat-transfer coefficient is defined as

$$q = h(T_s - T_b) \tag{5-51}$$

where $T_b$ is the bulk or mean temperature at a given cross section and $T_s$ is the corresponding surface temperature.

For laminar flow ($Re_D < 2100$) that is fully developed, both hydrodynamically and thermally, the Nusselt number has a constant value for a uniform wall temperature, $Nu_D = 3.66$. For a uniform heat flux through the tube wall, $Nu_D = 4.36$. In both cases, the thermal conductivity of the fluid in $Nu_D$ is evaluated at $T_b$. The distance $x$ required for a fully developed laminar velocity profile is given by $(x/D)/Re_D \approx 0.05$. The distance $x$ required for fully developed laminar thermal profiles is obtained from $[(x/D)/(Re_D\,Pr)] \approx 0.05$.

For a constant wall temperature, a fully developed laminar velocity profile, and a developing thermal profile, the average Nusselt number is estimated by [Hausen, *Allg. Waermetech.* **9:** 75 (1959)]

$$\overline{Nu}_D = 3.66 + \frac{0.0668(D/L)Re_D\,Pr}{1 + 0.04[(D/L)Re_D\,Pr]^{2/3}} \tag{5-52}$$

For large values of $L$, Eq. (5-52) approaches $Nu_D = 3.66$. Equation (5-52) also applies to developing velocity and thermal profile conditions if $Pr >> 1$. The properties in Eq. (5-52) are evaluated at the bulk mean temperature

$$\bar{T}_b = (T_{b,in} + T_{b,out})/2 \tag{5-53}$$

For a constant wall temperature with developing laminar velocity and thermal profiles, the average Nusselt number is approximated by [Sieder and Tate, *Ind. Eng. Chem.* **28:** 1429 (1936)]

$$\overline{Nu}_D = 1.86\left(\frac{D}{L}Re_D\,Pr\right)^{1/3}\left(\frac{\mu_b}{\mu_s}\right)^{0.14} \tag{5-54}$$

The properties, except for $\mu_s$, are evaluated at the bulk mean temperature per Eq. (5-53) and $0.48 < Pr < 16{,}700$ and $0.0044 < \mu_b/\mu_s < 9.75$.

For fully developed flow in the transition region between laminar and turbulent flow, and for fully developed turbulent flow, Gnielinski's [*Int. Chem. Eng.* **16:** 359 (1976)] equation is recommended:

$$Nu_D = \frac{(f/8)(Re_D - 1000)Pr}{1 + 12.7(f/8)^{1/2}(Pr^{2/3} - 1)}K \tag{5-55}$$

where $0.5 < Pr < 10^5$, $3000 < Re_D < 10^6$, $K = (Pr_b/Pr_s)^{0.11}$ for liquids ($0.05 < Pr_b/Pr_s < 20$), and $K = (T_b/T_s)^{0.45}$ for gases ($0.5 < T_b/T_s < 1.5$). The factor $K$ corrects for variable property effects. For smooth tubes, the Fanning friction factor $f$ for use with Eq. (5-55) is given by

$$f = (0.790 \ln Re_D - 1.64)^{-2} \qquad 3000 < Re_D < 10^6 \tag{5-56}$$

For rough pipes, approximate values of $Nu_D$ are obtained if $f$ is estimated by the Moody diagram of Sec. 6. Equation (5-55) is corrected for entrance effects per Eq. (5-60) and Table 5-3. Sieder and Tate [*Ind. Eng. Chem.* **28:** 1429 (1936)] recommend a simpler but less accurate equation for fully developed turbulent flow

$$Nu_D = 0.027\,Re_D^{4/5}\,Pr^{1/3}\left(\frac{\mu_b}{\mu_s}\right)^{0.14} \tag{5-57}$$

**TABLE 5-3 Effect of Entrance Configuration on the Values *C* and *n* in Eq. (5-60) for Pr ≈ 1 (Gases and Other Fluids with Pr about 1)**

| Entrance configuration | $C$ | $n$ |
|---|---|---|
| Long calming section | 0.9756 | 0.760 |
| Open end, 90° edge | 2.4254 | 0.676 |
| 180° return bend | 0.9759 | 0.700 |
| 90° round bend | 1.0517 | 0.629 |
| 90° elbow | 2.0152 | 0.614 |

where $0.7 < Pr < 16{,}700$, $Re_D < 10{,}000$, and $L/D > 10$. Equations (5-55) and (5-57) apply to both constant temperature and uniform heat flux along the tube. The properties are evaluated at the bulk temperature $T_b$, except for $\mu_s$, which is at the temperature of the tube. For $L/D$ greater than about 10, Eqs. (5-55) and (5-57) provide an estimate of $\overline{Nu}_D$. In this case, the properties are evaluated at the bulk mean temperature per Eq. (5-53). More complicated and comprehensive predictions of fully developed turbulent convection are available in Churchill and Zajic [*AIChE J.* **48:** 927 (2002)] and Yu, Ozoe, and Churchill [*Chem. Eng. Science*, **56:** 1781 (2001)].

For fully developed turbulent flow of liquid metals, the Nusselt number depends on the wall boundary condition. For a constant wall temperature [Notter and Sleicher, *Chem. Eng. Science*, **27:** 2073 (1972)],

$$Nu_D = 4.8 + 0.0156\,Re_D^{0.85}\,Pr^{0.93} \tag{5-58}$$

while for a uniform wall heat flux

$$Nu_D = 6.3 + 0.0167\,Re_D^{0.85}\,Pr^{0.93} \tag{5-59}$$

In both cases the properties are evaluated at $T_b$ and $0.004 < Pr < 0.01$ and $10^4 < Re_D < 10^6$.

Entrance effects for turbulent flow with simultaneously developing velocity and thermal profiles can be significant when $L/D < 10$. Shah and Bhatti correlated entrance effects for gases ($Pr \approx 1$) to give an equation for the average Nusselt number in the entrance region (in Kaka, Shah, and Aung, eds., *Handbook of Single-Phase Convective Heat Transfer*, Chap. 3, Wiley-Interscience, Hoboken, N.J., 1987).

$$\frac{\overline{Nu}_D}{Nu_D} = 1 + \frac{C}{(x/D)^n} \tag{5-60}$$

where $Nu_D$ is the fully developed Nusselt number and the constants $C$ and $n$ are given in Table 5-3 (Ebadian and Dong, Chap. 5 of Rohsenow, Hartnett, and Cho, *Handbook of Heat Transfer*, 3d ed., McGraw-Hill, New York, 1998, p. 5.31). The tube entrance configuration determines the values of $C$ and $n$ as shown in Table 5-3.

**Flow in Noncircular Ducts** The length scale in the Nusselt and Reynolds numbers for noncircular ducts is the hydraulic diameter $D_h = 4A_c/p$, where $A_c$ is the cross-sectional area for flow and $p$ is the wetted perimeter. For a circular annulus, $D_h = D_o - D_i$, where $D_i$ and $D_o$ are the inner and outer diameters. Nusselt numbers for fully developed laminar flow in a variety of noncircular ducts are given by Mills [*Heat Transfer*, 2d ed., Prentice Hall, Upper Saddle River, N.J., 1999, p. 307]. For turbulent flows, correlations for round tubes can be used with $D$ replaced by $D_h$.

For annular ducts, the accuracy of the Nusselt number given by Eq. (5-55) is improved by the following multiplicative factors [Petukhov and Roizen, *High Temp.* **2:** 65 (1964)].

$$\text{Inner tube heated} \qquad 0.86\left(\frac{D_i}{D_o}\right)^{-0.16}$$

$$\text{Outer tube heated} \qquad 1 - 0.14\left(\frac{D_i}{D_o}\right)^{0.6}$$

where $D_i$ and $D_o$ are the inner and outer diameters, respectively.

***Example 5-6 Turbulent Internal Flow*** Air at 300 K, 1 bar, and 0.05 kg/s enters a channel of a plate-type heat exchanger (Mills, *Heat Transfer*, 2d ed., Prentice Hall, Upper Saddle River, N.J., 1999) that measures 1 cm wide, 0.5 m high, and 0.8 m long. The walls are at 600 K, and the mass flow rate is 0.05 kg/s. The entrance has a 90° edge. We want to estimate the exit temperature of the air.

Our approach will use Eq. (5-55) to estimate the average heat-transfer coefficient, followed by application of Eq. (5-35) to calculate the exit temperature. We assume ideal gas behavior and an exit temperature of 500 K. The estimated bulk mean temperature of the air is, by Eq. (5-53), 400 K. At this temperature, the properties of the air are $Pr = 0.690$, $\mu = 2.301 \times 10^{-5}$ kg/(m · s), $k = 0.0338$ W/(m · K), and $c_p = 1014$ J/(kg · K).

We start by calculating the hydraulic diameter $D_h = 4A_c/p$. The cross-sectional area for flow $A_c$ is 0.005 m$^2$, and the wetted perimeter $p$ is 1.02 m. The hydraulic diameter $D_h = 0.01961$ m. The Reynolds number is

$$Re_{D_h} = \frac{\dot{m}D_h}{A_c\mu} = \frac{0.05(0.01961)}{0.005(2.301 \times 10^{-5})} = 8521$$

The flow is in the transition region, and Eqs. (5-56) and (5-55) apply:

$$f = 0.25(0.790 \ln \mathrm{Re}_{D_h} - 1.64)^{-2} = 0.25(0.790 \ln 8521 - 1.64)^{-2} = 0.008235$$

$$\mathrm{Nu}_D = \frac{(f/2)(\mathrm{Re}_D - 1000)(\mathrm{Pr})}{1 + 12.7(f/2)^{1/2}(\mathrm{Pr}^{2/3} - 1)} K$$

$$= \frac{(0.008235/2)(8521 - 1000)(0.690)}{1 + 12.7(0.008235/2)^{1/2}(0.690^{2/3} - 1)} \left(\frac{400}{600}\right)^{0.45} = 21.68$$

Entrance effects are included by using Eq. (5-60) for an open-end, 90° edge:

$$\overline{\mathrm{Nu}}_D = \left[1 + \frac{C}{(x/D)^n}\right] \mathrm{Nu}_D = \left[1 + \frac{2.4254}{(0.8/0.01961)^{0.676}}\right](21.68) = 25.96$$

The average heat-transfer coefficient becomes

$$\bar{h} = \frac{k}{D_h} \overline{\mathrm{Nu}}_D = \frac{0.0338}{0.01961}(25.96) = 44.75 \frac{\mathrm{W}}{\mathrm{m}^2 \cdot \mathrm{K}}$$

The exit temperature is calculated from Eq. (5-35):

$$T(L) = T_s - (T_s - T_{\mathrm{in}}) \exp\left(-\frac{\bar{h} p L}{\dot{m} c_p}\right)$$

$$= 600 - (600 - 300) \exp\left[-\frac{44.75(1.02)0.8}{0.05(1014)}\right] = 450 \mathrm{K}$$

We conclude that our estimated exit temperature of 500 K is too high. We could repeat the calculations, using fluid properties evaluated at a revised bulk mean temperature of 375 K.

**Coiled Tubes** For turbulent flow inside helical coils, with tube inside radius $a$ and coil radius $R$, the Nusselt number for a straight tube $\mathrm{Nu}_s$ is related to that for a coiled tube $\mathrm{Nu}_c$ by [Rohsenow, Hartnett, and Cho, *Handbook of Heat Transfer*, 3d ed., McGraw-Hill, New York, 1998, p. 5.90]

$$\frac{\mathrm{Nu}_C}{\mathrm{Nu}_S} = 1.0 + 3.6\left(1 - \frac{a}{R}\right)\left(\frac{a}{R}\right)^{0.8} \tag{5-61}$$

where $2 \times 10^4 < \mathrm{Re}_D < 1.5 \times 10^5$ and $5 < R/a < 84$. For lower Reynolds numbers ($1.5 \times 10^3 < \mathrm{Re}_D < 2 \times 10^4$), the same source recommends

$$\frac{\mathrm{Nu}_c}{\mathrm{Nu}_s} = 1.0 + 3.4\frac{a}{R} \tag{5-62}$$

**External Flows** For a single cylinder in cross flow, Churchill and Bernstein [*J. Heat Transfer*, **99:** 300 (1977)] recommend

$$\overline{\mathrm{Nu}}_D = 0.3 + \frac{0.62 \mathrm{Re}_D^{1/2} \mathrm{Pr}^{1/3}}{[1 + (0.4/\mathrm{Pr})^{2/3}]^{1/4}} \left[1 + \left(\frac{\mathrm{Re}_D}{282{,}000}\right)^{5/8}\right]^{4/5} \tag{5-63}$$

where $\overline{\mathrm{Nu}}_D = \bar{h}D/k$. Equation (5-63) is for all values of $\mathrm{Re}_D$ and Pr, provided that $\mathrm{Re}_D \mathrm{Pr} > 0.4$. The fluid properties are evaluated at the film temperature $(T_e + T_s)/2$, where $T_e$ is the free-stream temperature and $T_s$ is the surface temperature. Equation (5-63) also applies to the uniform heat flux boundary condition provided $\bar{h}$ is based on the perimeter-averaged temperature difference between $T_s$ and $T_e$.

For an isothermal spherical surface, Whitaker [*AIChE*, **18:** 361 (1972)] recommends

$$\overline{\mathrm{Nu}}_D = 2 + \left(0.4 \mathrm{Re}_D^{1/2} + 0.06 \mathrm{Re}_D^{2/3}\right) \mathrm{Pr}^{0.4} \left(\frac{\mu_e}{\mu_s}\right)^{1/4} \tag{5-64}$$

This equation is based on data for $0.7 < \mathrm{Pr} < 380$, $3.5 < \mathrm{Re}_D < 8 \times 10^4$, and $1 < \mu_e/\mu_s < 3.2$. The properties are evaluated at the free stream temperature $T_e$, with the exception of $\mu_s$, which is evaluated at the surface temperature $T_s$.

The average Nusselt number for laminar flow over an isothermal flat plate of length $x$ is estimated from [Churchill and Ozoe, *J. Heat Transfer*, **95:** 416 (1973)]

$$\overline{\mathrm{Nu}}_x = \frac{1.128 \mathrm{Pr}^{1/2} \mathrm{Re}_x^{1/2}}{[1 + (0.0468/\mathrm{Pr})^{2/3}]^{1/4}} \tag{5-65}$$

This equation is valid for all values of Pr as long as $\mathrm{Re}_x$ Pr > 100 and $\mathrm{Re}_x < 5 \times 10^5$. The fluid properties are evaluated at the film temperature $(T_e + T_s)/2$, where $T_e$ is the free stream temperature and $T_s$ is the surface temperature. For a uniformly heated flat plate, the local Nusselt number is given by [Churchill and Ozoe, *J. Heat Transfer*, **95:** 78 (1973)]

$$\mathrm{Nu}_x = \frac{0.886 \mathrm{Pr}^{1/2} \mathrm{Re}_x^{1/2}}{\left[1 + (0.0207/\mathrm{Pr})^{2/3}\right]^{1/4}} \tag{5-66}$$

where again the properties are evaluated at the film temperature.

The average Nusselt number for turbulent flow over a smooth, isothermal flat plate of length $x$ is given by [Mills, *Heat Transfer*, 2d ed., Prentice Hall, Upper Saddle River, N.J., 1999, p. 315]

$$\overline{\mathrm{Nu}}_x = 0.664 \mathrm{Re}_{\mathrm{cr}}^{1/2} \mathrm{Pr}^{1/3} + 0.036 \mathrm{Re}_x^{0.8} \mathrm{Pr}^{0.43} \left[1 - \left(\frac{\mathrm{Re}_{\mathrm{cr}}}{\mathrm{Re}_x}\right)^{0.8}\right] \tag{5-67}$$

The critical Reynolds number $\mathrm{Re}_{\mathrm{cr}}$ is typically taken as $5 \times 10^5$, $\mathrm{Re}_{\mathrm{cr}} < \mathrm{Re}_x < 3 \times 10^7$, and $0.7 < \mathrm{Pr} < 400$. The fluid properties are evaluated at the film temperature $(T_e + T_s)/2$, where $T_e$ is the free-stream temperature and $T_s$ is the surface temperature. Equation (5-67) also applies to the uniform heat flux boundary condition provided $\bar{h}$ is based on the average temperature difference between $T_s$ and $T_e$.

**Flow-through Tube Banks** Aligned and staggered tube banks are sketched in Fig. 5-6. The tube diameter is $D$, and the transverse and longitudinal pitches are $S_T$ and $S_L$. The fluid velocity upstream of the tubes is $V_\infty$. To estimate the overall heat-transfer coefficient for the tube bank, Mills [*Heat Transfer*, 2d ed., Prentice-Hall, 1999, p. 348] proceeds as follows. The Reynolds number for use in Eq. (5-63) is recalculated with an effective average velocity in the space between adjacent tubes:

$$\frac{\overline{V}}{V_\infty} = \frac{S_T}{S_T - (\pi/4)D} \tag{5-68}$$

The heat-transfer coefficient increases from row 1 to about row 5 of the tube bank. The average Nusselt number for a tube bank with 10 or more rows is

$$\overline{\mathrm{Nu}}_D^{10+} = \Phi \overline{\mathrm{Nu}}_D^{1} \tag{5-69}$$

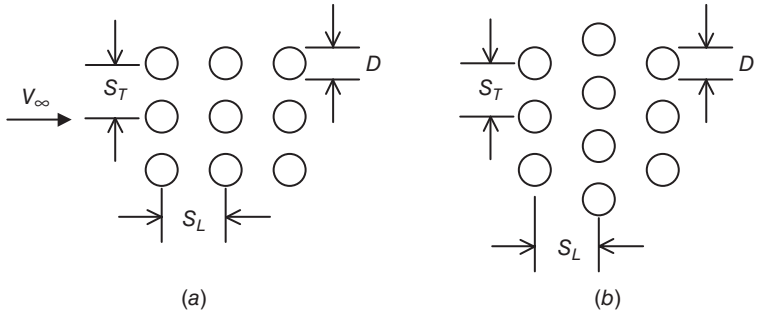


**FIG. 5-6** (*a*) Aligned and (*b*) staggered tube bank configurations. The fluid velocity upstream of the tubes is $V_\infty$.

where $\Phi$ is an arrangement factor and $\overline{\mathrm{Nu}}_D^1$ is the Nusselt number for the first row, calculated by using the velocity in Eq. (5-68). The arrangement factor is calculated as follows. Define dimensionless pitches as $P_T = S_T/D$ and $P_L/D$ and calculate a factor $\psi$ as follows.

$$\Psi = \begin{cases} 1 - \dfrac{\pi}{4P_t} & \text{if } P_L \geq 1 \\ 1 - \dfrac{\pi}{4P_T P_L} & \text{if } P_L < 1 \end{cases} \tag{5-70}$$

The arrangement factors are

$$\Phi_{\text{aligned}} = 1 + \frac{0.7}{\Psi^{1.5}} \frac{S_L/S_T - 0.3}{(S_L/S_T + 0.7)^2} \tag{5-71}$$

$$\Phi_{\text{staggered}} = 1 + \frac{2}{3P_L} \tag{5-72}$$

If there are fewer than 10 rows,

$$\overline{\mathrm{Nu}}_D = \frac{1 + (N-1)\Phi}{N} \overline{\mathrm{Nu}}_D^1 \tag{5-73}$$

where $N$ is the number of rows.

The fluid properties for gases are evaluated at the average mean film temperature $[(T_{\text{in}} + T_{\text{out}})/2 + T_s]/2$. For liquids, properties are evaluated at the bulk mean temperature $(T_{\text{in}} + T_{\text{out}})/2$, with $\overline{\mathrm{Nu}}_D$ from Eq. (5-73) being multiplied by a Prandtl number correction $(\mathrm{Pr}_s/\mathrm{Pr}_b)^{-0.11}$ for cooling and $(\mathrm{Pr}_s/\mathrm{Pr}_b)^{-0.25}$ for heating.

**Heat Transfer to Nonevaporating Falling Films** When a subcooled liquid flows in a thin layer down a vertical surface, there is little or no evaporation and the heat-transfer coefficient is defined by $q/(T_s - T_b)$ where $T_s$ is the surface temperature and $T_b$ is the bulk fluid temperature.

For laminar flow ($\mathrm{Re}_\delta < 20$–$30$) the heat-transfer coefficient is given by the equation of Hewitt [Rohsenow, Hartnett, and Cho, *Handbook of Heat Transfer*, 3d ed., McGraw-Hill, New York, 1998, chap. 15]:

$$h = \frac{q}{T_s - T_b} = \frac{280}{141} \left( \frac{4\rho_l^2 g k_l^3}{3\mu_l^2} \right)^{1/3} \mathrm{Re}_\delta^{-1/3} \tag{5-74}$$

where the Reynolds number of the falling film is defined as $\mathrm{Re}_\delta = 4\Gamma/\mu_l$ and $\Gamma$ is the mass rate of flow of liquid per unit length normal to the direction of flow [kg/(s · m)]. To account for wavy laminar ($30$–$50 < \mathrm{Re}_\delta < 1600$) and turbulent ($\mathrm{Re}_\delta > 1600$) flow, Wilkie [Rohsenow, Hartnett, and Cho, *Handbook of Heat Transfer*, 3d ed., McGraw-Hill, New York, 1998, chap. 15] recommends

$$\frac{h\delta}{k_l} = C_0 \mathrm{Re}_\delta^m \mathrm{Pr}_l^{0.344} \tag{5-75}$$

where $C_0 = 0.029$ and $m = 0.533$ for $\mathrm{Re}_\delta > 1600$, $C_0 = 0.212 \times 10^{-3}$ and $m = 1.2$ for $1600 < \mathrm{Re}_\delta < 3200$, and $C_0 = 0.181 \times 10^{-2}$ and $m = 0.933$ for $\mathrm{Re}_\delta > 3200$. Equation (5-75) provides an average heat-transfer coefficient, and the value of the film thickness $\delta$ for $\mathrm{Re}_\delta < 1600$ is given by

$$\delta = \left( \frac{3\mu_l \Gamma}{\rho_l^2 g} \right)^{1/3} \tag{5-76}$$

and for $\mathrm{Re}_\delta > 1600$ by

$$\left( \frac{\delta^3 \rho_l^2 g}{\mu_l^2} \right)^{0.5} = 0.137 \mathrm{Re}_\delta^{0.75} \tag{5-77}$$

## JACKETS AND COILS OF AGITATED VESSELS

See Secs. 11 and 18.

## NONNEWTONIAN FLUIDS

Many real fluids are nonnewtonian. Section 6 introduces the dynamics of nonnewtonian fluids in laminar and turbulent regimes. Heat transfer is reviewed by Hartnett and Cho [Rohsenow, Hartnett, and Cho, *Handbook of Heat Transfer*, 3d ed., McGraw-Hill, New York, 1998, chap. 13]. They provide equations, tables, and charts for estimating the Nusselt number in laminar and turbulent internal flow and refer to the literature for external convection, free convection, boiling, suspensions and surfactants, and flow of food products.

# HEAT TRANSFER WITH CHANGE OF PHASE

In any process in which a material changes phase, the addition or removal of heat is required to balance the latent heat of the change of phase plus any other sensible heating or cooling that occurs. Heat may be transferred by any one of or a combination of conduction, convection, and radiation. Change of phase involves simultaneous mass and heat transfer.

## CONDENSATION

**Condensation Mechanisms** Condensation occurs when a saturated vapor comes in contact with a surface whose temperature is below the saturation temperature. A film of condensate forms on the surface, and the thickness of the film increases as the liquid flows down the surface. This is called *film-type condensation*.

Another type of condensation, called *dropwise*, occurs when the wall is not uniformly wetted by the condensate, with the result that the condensate appears in many small droplets on the surface. The individual droplets grow, coalesce, and finally form a rivulet.

Film-type condensation is more common and more dependable. Dropwise condensation normally needs to be promoted by introducing an impurity into the vapor stream. Substantially higher (6 to 18 times) coefficients are obtained for dropwise condensation of steam, but it is difficult to maintain. The equations below are for the film type only. For additional details, see Rohsenow, Hartnett, and Cho, *Handbook of Heat Transfer*, 3d ed., McGraw-Hill, New York, 1998 and Bergman, Lavine, Incropera, and DeWitt, *Fundamentals of Heat and Mass Transfer*, 7th ed., Wiley, Hoboken, N.J., 2011.

The *Reynolds number* of the condensate film (falling film) is defined as $\mathrm{Re}_\delta = 4\Gamma/\mu_l$, where $\Gamma$ is the mass rate of flow of condensate per unit length normal to the direction of flow [kg/(s · m)] and $\mu_l$ is the liquid viscosity. For $\mathrm{Re}_\delta < 30$ the flow is laminar and free of waves. When $30 < \mathrm{Re}_\delta < 1800$, the flow is wavy and rippled. At $\mathrm{Re}_\delta > 1800$ the flow is turbulent. The Reynolds number can also be written as

$$\mathrm{Re}_\delta = \frac{4\dot{m}}{\mu_l} = \frac{4\rho_l u_m \delta}{\mu_l} \tag{5-78}$$

where $\delta$ is the film thickness.

**Condensation Coefficients**

***Vertical Tubes and Plates*** For a Reynolds number < 30, the average Nusselt number for laminar condensate films is

$$\overline{\mathrm{Nu}}_L = \frac{\bar{h}_L L}{k_l} = 0.943 \left[ \frac{\rho_l g (\rho_l - \rho_v) h_{fg}' L^3}{\mu_l k_l (T_{\text{sat}} - T_s)} \right]^{1/4} \tag{5-79}$$

where $L$ is the length of the cooled surface and

$$h_{fg}' = h_{fg} + 0.68 c_{p,l} (T_{\text{sat}} - T_s) \tag{5-80}$$

The liquid properties in Eqs. (5-79) and (5-80) are evaluated at the film temperature, $T_f = (T_{\text{sat}} + T_s)/2$, and $\rho_v$ and $h_{fg}$ are at $T_{\text{sat}}$. The vapor density in Eq. (5-79) is frequently neglected relative to the liquid density.

The total rate of heat transfer to the surface at temperature $T_s$ is given by

$$\dot{Q} = \bar{h}_L A (T_{\text{sat}} - T_s) \tag{5-81}$$

and the rate of condensation is

$$\dot{m} = \frac{\dot{Q}}{h_{fg}'} \tag{5-82}$$

To estimate average Nusselt numbers for laminar, wavy, and turbulent flow, Bergman et al. (2011) recommend the following procedure. A dimensionless parameter $P$ is defined by combining Eqs. (5-82) and (5-78) to give an average modified Nusselt number with characteristic length $\left(\nu_l^2/g\right)^{1/3}$:

$$\begin{aligned} \mathrm{Re}_\delta &= 4P\frac{\bar{h}_L\left(\nu_l^2/g\right)^{1/3}}{k_l} = 4P\overline{\mathrm{Nu}}_L \\ P &= \frac{k_l L(T_{\mathrm{sat}} - T_s)}{\mu_l h_{fg}'\left(\nu_l^2/g\right)^{1/3}} \end{aligned} \tag{5-83}$$

The modified average Nusselt numbers for $\mathrm{Re}_\delta < 30$, $30 < \mathrm{Re}_\delta < 1800$, and $\mathrm{Re}_\delta > 1800$ become

$$\overline{\mathrm{Nu}}_L = \frac{\bar{h}_L\left(\nu_l^2/g\right)^{1/3}}{k_l} = 0.943P^{-1/4} \qquad (P \le 15.8) \tag{5-84}$$

$$\overline{\mathrm{Nu}}_L = \frac{\bar{h}_L\left(\nu_l^2/g\right)^{1/3}}{k_l} = \frac{1}{P}(0.68P + 0.89)^{0.82} \qquad (15.8 \le P \le 2530) \tag{5-85}$$

$$\overline{\mathrm{Nu}}_L = \frac{\bar{h}_L\left(\nu_l^2/g\right)^{1/3}}{k_l} = \frac{1}{P}\left[(0.024P - 53)\mathrm{Pr}_l^{1/2} + 89\right]^{4/3} \qquad (P \ge 2530, \mathrm{Pr}_l \ge 1) \tag{5-86}$$

Equations (5-84) and (5-79) are identical if $\rho_l >> \rho_v$. The fluid properties for Eqs. (5-84), (5-85), and (5-86) are evaluated as described below Eq. (5-80).

***Horizontal Smooth Tubes*** For laminar film condensation on horizontal smooth tubes the average Nusselt number is given by

$$\overline{\mathrm{Nu}}_D = \frac{\bar{h}_D D}{k_l} = 0.729\left[\frac{\rho_l g(\rho_l - \rho_v)h_{fg}' D^3}{\mu_l k_l (T_{\mathrm{sat}} - T_s)}\right]^{1/4} \tag{5-87}$$

The fluid properties for Eq. (5-87) are evaluated as described below Eq. (5-80).

***Banks of Horizontal Tubes*** In the idealized case of $N$ tubes in a vertical row where the total condensate flows smoothly from one tube to the one beneath it, without splashing, and still in laminar flow on the tube, the mean condensing coefficient $h_N$ for the entire row of $N$ tubes is related to the condensing coefficient for the top tube $h_1$ by

$$h_N = h_1 N^{-s} \tag{5-88}$$

The standard Nusselt theory gives $s = 1/4$ but others recommend $s = 1/6$.

## EVAPORATING LIQUID FILMS ON VERTICAL WALLS

Mills' presentation of heat transfer to evaporating falling films [*Heat Transfer*, 2d ed., Prentice Hall, Upper Saddle River, N.J., 1999, pp. 681–685] is given here, with minor modifications. The Reynolds number of the evaporating falling film is defined as $\mathrm{Re}_\delta = 4\Gamma/\mu_l$ and the Nusselt number for evaporation is

$$\mathrm{Nu}_L = \frac{h_L\left(\nu_l^2/g\right)^{1/3}}{k_l} \tag{5-89}$$

For laminar flow the local Nusselt number is

$$\mathrm{Nu} = \left(\frac{3}{4}\mathrm{Re}_\delta\right)^{-1/3} \qquad 0 < \mathrm{Re}_\delta < 30, \text{ laminar} \tag{5-90}$$

For wavy laminar and turbulent flows, the correlations of experimental data for water by Chun and Seban [*J. Heat Transfer*, 93: 391–396 (1971)] give

$$\mathrm{Nu} = 0.822\,\mathrm{Re}_\delta^{-0.22} \qquad 30 < \mathrm{Re}_\delta < \mathrm{Re}_{\mathrm{tr}}, \text{ wavy laminar} \tag{5-91}$$

$$\mathrm{Nu} = 0.0038\,\mathrm{Re}_\delta^{-0.4}\,\mathrm{Pr}_l^{0.65} \qquad \mathrm{Re}_{\mathrm{tr}} < \mathrm{Re}_\delta, \text{ turbulent} \tag{5-92}$$

where

$$\mathrm{Re}_{\mathrm{tr}} = 5800\,\mathrm{Pr}_l^{0.65} \tag{5-93}$$

Liquid properties in Eqs. (5-88) to (5-92) can be approximated by evaluation at the film temperature: $T_f = (T_{\mathrm{sat}} + T_s)/2$ with $h_{fg}$ at $T_{\mathrm{sat}}$. An energy balance for a vertical surface of length $L$ is

$$\frac{L}{\left(\nu_l^2/g\right)^{1/3}} = -\frac{\mathrm{Pr}_l}{4\,\mathrm{Ja}_l}\int_{\mathrm{Re}_0}^{\mathrm{Re}_L}\frac{d\,\mathrm{Re}}{\mathrm{Nu}} \tag{5-94}$$

where $L$ is the length of the surface in the direction of flow and the Jakob number for the liquid is defined as

$$Ja_l = \frac{c_{pl}(T_s - T_{\mathrm{sat}})}{h_{fg}} \tag{5-95}$$

The use of Eqs. (5-88) to (5-95) to estimate an evaporation rate is illustrated by Example 5-7 which is based on an example in Mills [*Heat Transfer*, 2d ed., Prentice Hall, Upper Saddle River, N.J., 1999, pp. 684–685].

***Example 5-7 Evaporating Falling Film*** Water is fed to the outer surface of a single, vertical, 5-cm outer-diameter (OD) tube at the rate of 0.01 kg/s. The tube is 5 m long, and its surface is kept at 311 K by condensing steam on the inside. The saturation temperature at the pressure outside the tube is 308 K. Estimate the evaporation rate. We start by recalling that the liquid properties are approximated at the film temperature [$T_f = (T_s + T_{\mathrm{sat}})/2 = (311 + 308)/2 = 310$ K] and that the enthalpy of vaporization $h_{fg}$ is evaluated at the saturation temperature. At 308 K, $h_{fg} = 2.418 \times 10^6$ J/kg. At the film temperature, $k_l = 0.628$ W/(m·K), $\rho_l = 993$ kg/m$^3$, $c_{pl} = 4174$ J/(kg·K), $\mu_l = 6.95 \times 10^{-4}$ kg/(m·s), $\nu_l = 0.700 \times 10^{-6}$ m$^2$/s, and $\mathrm{Pr}_l = 4.6$.

The film Reynolds number at the top of the tube is

$$\mathrm{Re}_0 = \frac{4\Gamma_0}{\mu_l} = \frac{4\dot{m}_0}{\pi D\mu_l} = \frac{4(0.01)}{\pi(0.05)6.95\times10^{-4}} = 366$$

The Reynolds number for transition from wavy laminar to turbulent flow is

$$\mathrm{Re}_{\mathrm{tr}} = 5800\,\mathrm{Pr}_l^{-1.06} = 5800(4.6)^{-1.06} = 1151$$

Because this is greater than 366 we will assume that we remain in the wavy laminar regime and will check $\mathrm{Re}_L$ by using Eq. (5-94).

$$\frac{L}{\left(\nu_l^2/g\right)^{1/3}} = -\frac{\mathrm{Pr}_l}{4\,\mathrm{Ja}_l}\int_{\mathrm{Re}_0}^{\mathrm{Re}_l}\frac{d\,\mathrm{Re}}{\mathrm{Nu}} = -\frac{\mathrm{Pr}_l}{4\,\mathrm{Ja}_l}\int_{\mathrm{Re}_0}^{\mathrm{Re}_l}\frac{d\,\mathrm{Re}}{0.822\,\mathrm{Re}^{-0.22}}$$

Integrating and solving for $\mathrm{Re}_L$ give

$$\mathrm{Re}_L^{1.22} = -\frac{4.01L}{(\nu_l^2/g)^{1/3}}\frac{\mathrm{Ja}_l}{\mathrm{Pr}_l} + \mathrm{Re}_0^{1.22} = 730$$

where

$$\mathrm{Ja}_l = \frac{c_{pl}(T_s - T_{\mathrm{sat}})}{h_{fg}} = \frac{4174(311-308)}{2.418\times10^6} = 5.18\times10^{-3}$$

$$\left(\frac{\nu_l^2}{g}\right)^{1/3} = \left[\frac{(0.700\times10^{-6})^2}{9.81}\right]^{1/3} = 3.68\times10^{-5}\ \mathrm{m}$$

We conclude that the film is entirely in the wavy laminar regime. Solving the film Reynolds number for the mass flow rate at $L$ gives

$$\dot{m}_L = \frac{\pi D\mu_l\,\mathrm{Re}_L}{4} = \frac{\pi(0.05)6.95\times10^{-4}(222)}{4} = 6.07\times10^{-3}\ \mathrm{kg/s}$$

The evaporation rate is

$$\dot{m}_{\mathrm{vap}} = \dot{m}_0 - \dot{m}_L = 0.01 - 0.00607 = 0.0039\ \mathrm{kg/s}$$

## POOL BOILING

*Pool boiling* refers to the type of boiling experienced when the heating surface is surrounded by a large body of fluid which is not flowing at any appreciable velocity and is agitated only by the motion of the bubbles and by natural convection currents. Two types of pool boiling are possible: *subcooled* pool boiling, in which the bulk fluid temperature is below the saturation

temperature, resulting in collapse of the bubbles before they reach the surface, and *saturated* pool boiling, with the bulk temperature equal to the saturation temperature, resulting in net vapor generation. The following presentation draws heavily from Mills [*Heat Transfer*, 2d ed. (1999)].

In the general shape of the curve relating the heat-transfer coefficient to $\Delta T = T_s - T_{sat}$, the difference between the surface temperature and the saturation temperature is reasonably well understood. The familiar boiling curve was originally demonstrated experimentally by Nukiyama [*J. Soc. Mech. Eng.* (*Japan*), **37:** 367 (1934)]. This curve points out one of the great dilemmas for boiling-equipment designers. They are faced with at least four heat-transfer regimes in pool boiling: natural convection (+), nucleate boiling (+), transition to film boiling (−), and film boiling (+). The signs indicate the sign of the derivative $dq/(d\,\Delta T)$. In the transition to film boiling, the heat-transfer rate *decreases* with $\Delta T$. Here we consider nucleate boiling, the peak heat flux, and film boiling.

*Nucleate boiling* occurs in kettle-type and natural-circulation reboilers commonly used in the process industries. High rates of heat transfer are obtained as a result of bubble formation at the liquid-solid interface. The heat-transfer coefficient is defined by

$$q = h(T_s - T_{sat}) \tag{5-96}$$

where $T_{sat}$ is at the system pressure. The characteristic length used to define the Nusselt number is

$$L_c = \left[\frac{\sigma}{(\rho_l - \rho_v)g}\right]^{1/2} \tag{5-97a}$$

and the Nusselt number is given by Rohsenow [*Trans. ASME,* **74:** 969 (1952)] as

$$\mathrm{Nu} = \frac{hL_c}{k_l} = \frac{\mathrm{Ja}_l^2}{C_{nb}^3\,\mathrm{Pr}_l^m} \tag{5-97b}$$

The *Jakob number* is defined as

$$\mathrm{Ja}_l = \frac{c_{pl}(T_s - T_{sat})}{h_{fg}} \tag{5-98}$$

All properties in Eq. (5-97b), including the vapor density, are evaluated at $T_{sat}$. Typical values for the constant $C_{nb}$ and the exponent $m$ are given in Table 5-4. Equations (5-96) and (5-97b) imply that the rate of heat transfer is proportional to $\Delta T^3$. Errors of 100 percent in $q$ and 25 percent in $\Delta T$ are possible with Eq. (5-97b). The designer of heat-transfer equipment is usually more concerned with not exceeding the peak heat flux $q_{max}$ rather than in knowing accurate values of $q$ and $\Delta T$.

**TABLE 5-4 The Constant $C_{nb}$ and Exponent $m$ for Use with Rohsenow Eq. (5-97)**

| Liquid | Surface | $C_{nb}$ | $m$ |
|---|---|---|---|
| Water | Copper, scored | 0.0068 | 2.0 |
| Water | Copper, polished | 0.013 | 2.0 |
| Water | Stainless steel, mechanically polished | 0.013 | 2.0 |
| Ethanol | Chromium | 0.0027 | 4.1 |
| *n*-Pentane | Chromium | 0.015 | 4.1 |

The *peak heat flux* may be predicted by the Kutateladse-Zuber [*Trans. ASME,* **80:** 711 (1958)] relationship:

$$q_{max} = C_{max} h_{fg}\left[\sigma\rho_v^2(\rho_l - \rho_v)g\right]^{1/4} \tag{5-99}$$

where $C_{max}$ is approximately 0.15. All properties in Eq. (5-99) are evaluated at $T_{sat}$.

For laminar *film boiling,* Bromley's [*Chem. Eng. Prog.* **46:** 221 (1950)] correlation may be used:

$$\bar{h} = C_{fb}\left[\frac{(\rho_l - \rho_v)gh'_{fg}k_v^3}{\nu_v L(T_s - T_{sat})}\right]^{1/4} \tag{5-100a}$$

where $L$ is a characteristic length. For spheres and horizontal cylinders it is the diameter $D$. The constant $C_{fb}$ is 0.62 for a horizontal cylinder, 0.67 for a sphere, and 0.71 for a planar vertical surface. The modified latent heat is

$$h'_{fg} = h_{fg} + 0.35c_{pv}(T_s - T_{sat}) \tag{5-100b}$$

In Eqs. (5-99) and (5-100*a*), $h_{fg}$, $\rho_l$, and $\sigma$ are evaluated at $T_{sat}$; all other properties are at the mean film temperature.

## INTRODUCTION

Heat transfer by thermal radiation involves the transport of electromagnetic (EM) energy from a source to a sink. In contrast to other modes of heat transfer, radiation does not require the presence of an intervening medium, e.g., as in the irradiation of the earth by the sun. Most industrially important applications of radiative heat transfer occur in the *near infrared* portion of the EM spectrum (0.7 through 25 μm) and may extend into the *far infrared* region (25 to 1000 μm). For very high temperature sources, such as solar radiation, relevant wavelengths encompass the entire *visible region* (0.4 to 0.7 μm) and may extend down to 0.2 μm in the *ultraviolet* (0.01- to 0.4-μm) portion of the EM spectrum. Radiative transfer can also exhibit unique *action-at-a-distance* phenomena that do not occur in other modes of heat transfer. Radiation differs from conduction and convection with regard to not only mathematical characterization but also its fourth power dependence on temperature. Thus it is usually dominant in high-temperature combustion applications. The temperature at which radiative transfer accounts for roughly one-half of the total heat loss from a surface in air depends on such factors as surface *emissivity* and the convection coefficient. For pipes in free convection, radiation is important at ambient temperatures. For fine wires of low emissivity, it becomes important at temperatures associated with bright red heat (1300 K). Combustion gases at furnace temperatures typically lose more than 90 percent of their energy through radiative emission from constituent carbon dioxide, water vapor, and particulate matter. Radiative transfer methodologies are important in myriad engineering applications. These include semiconductor processing, illumination theory, and gas turbines and rocket nozzles, as well as furnace design.

## THERMAL RADIATION FUNDAMENTALS

In a vacuum, the wavelength λ, frequency ν, and wave number η for electromagnetic radiation are interrelated by $\lambda = c/\nu = 1/\eta$, where $c$ is the speed of light. Frequency is independent of the index of refraction of a medium $n$, but both the speed of light and the wavelength in the medium vary according to $c_m = c/n$ and $\lambda_m = \lambda/n$. When a radiation beam passes into a medium of different refractive index, not only does its wavelength change but also its direction does (Snell's law) as well as the magnitude of its intensity. In most engineering heat-transfer calculations, wavelength is usually employed to

characterize radiation while wave number is often used in gas spectroscopy. For a vacuum, air at ambient conditions, and most gases, $n \approx 1.0$. For this reason this presentation sometimes does not distinguish between $\lambda$ and $\lambda_m$. *Dielectric materials* exhibit $1.4 < n < 4$, and the speed of light decreases considerably in such media.

In radiation heat transfer, the *monochromatic intensity* $I_\lambda \equiv I_\lambda(\vec{\mathbf{r}}, \vec{\Omega}, \lambda)$, is a *fundamental* (scalar) *field variable* which characterizes EM energy transport. Intensity defines the radiant energy flux passing through an infinitesimal area *dA*, oriented *normal* to a radiation beam of arbitrary direction $\vec{\Omega}$. At steady state, the monochromatic intensity is a function of position $\vec{\mathbf{r}}$, direction $\vec{\Omega}$, and wavelength and has units of $W/(m^2 \cdot sr \cdot \mu m)$. In the general case of an *absorbing-emitting* and *scattering* medium, characterized by some absorption coefficient $K(m^{-1})$, intensity in the direction $\vec{\Omega}$ will be modified by attenuation and by *scattering* of radiation into and out of the beam. For the special case of a nonabsorbing (transparent), nonscattering medium of constant refractive index, the radiation intensity *is constant and independent of position in a given direction* $\vec{\Omega}$. This circumstance arises in *illumination theory* where the light intensity in a room is constant in a *given direction* but may vary with respect to *all other directions*. The basic conservation law for radiation intensity is termed the *equation of transfer* or *radiative transfer equation*. The equation of transfer is a *directional* energy balance and mathematically is an *integrodifferential equation*. The relevance of the transport equation to radiation heat transfer is discussed in many sources; see, e.g., Modest, Michael F., *Radiative Heat Transfer,* 3d ed., Academic Press, New York, 2013, or Howell, John, M. Pinar Mengüç, and Robert Siegel, *Thermal Radiative Heat Transfer,* 6th ed., CRC Press, Boca Raton, Fla., 2015.

**Introduction to Radiation Geometry** Consider a homogeneous medium of constant refractive index *n*. A pencil of radiation originates at differential area element $dA_i$ and is incident on differential area element $dA_j$. Designate $\vec{\mathbf{n}}_i$ and $\vec{\mathbf{n}}_j$ as the unit vectors normal to $dA_i$ and $dA_j$, and let *r*, with unit direction vector $\vec{\Omega}$, define the distance of separation between the area elements. Moreover, $\phi_i$ and $\phi_j$ denote the *confined angles* between $\vec{\Omega}$ and $\vec{\mathbf{n}}_i$ and $\vec{\mathbf{n}}_j$, respectively [i.e., $\cos\phi_i \equiv \cos(\vec{\Omega}, \vec{r}_i)$ and $\cos\phi_j \equiv \cos(\vec{\Omega}, \vec{r}_j)$]. As the beam travels toward $dA_j$, it will *diverge* and subtend a solid angle

$$d\Omega_j = \frac{\cos\phi_j}{r^2} dA_j \qquad \text{in steradian (sr) units}$$

at $dA_j$. Moreover, the projected area of $dA_i$ in the direction of $\vec{\Omega}$ is given by $\cos(\vec{\Omega}, \vec{r}_j)\, dA_i = \cos\phi_i\, dA_i$. Multiplication of the intensity $I_\lambda \equiv I_\lambda(\vec{r}, \vec{\Omega}, \lambda)$ by $d\Omega_j$ and the apparent area of $dA_i$ then yields an expression for the (*differential*) net *monochromatic radiant energy flux* $dQ_{ij}$ originating at $dA_i$ and intercepted by $dA_j$.

$$dQ_{i,j} \equiv I_\lambda(\vec{\Omega}, \lambda) \cos\phi_i \cos\phi_j\, dA_i\, dA_j / r^2 \tag{5-101}$$

The *hemispherical emissive power** *E* is defined as the radiant flux density ($W/m^2$) associated with emission from an element of surface area *dA* into a surrounding unit hemisphere whose base is coplanar with *dA*. If the monochromatic intensity $I_\lambda(\vec{\Omega}, \lambda)$ of emission from the surface is *isotropic* (independent of the angle of emission $\vec{\Omega}$), then Eq. (5-101) may be integrated over the $2\pi$ sr of the surrounding unit hemisphere to yield the simple relation $E_\lambda = \pi I_\lambda$, where $E_\lambda \equiv E_\lambda(\lambda)$ is defined as the monochromatic or *spectral* hemispherical emissive power.

**Blackbody Radiation** Engineering calculations involving thermal radiation normally employ the *hemispherical blackbody emissive power* as the thermal driving force analogous to temperature in the cases of conduction and convection. A *blackbody* is a theoretical idealization for a *perfect theoretical radiator*; i.e., it absorbs all incident radiation without reflection and emits isotropically. In practice, soot-covered surfaces sometimes approximate blackbody behavior. Let $E_{b,\lambda} = E_{b,\lambda}(T, \lambda)$ denote the monochromatic blackbody hemispherical emissive power *frequency function* defined such that $E_{b,\lambda}(T, \lambda)d\lambda$ represents the fraction of blackbody energy lying in the wavelength region from $\lambda$ to $\lambda + d\lambda$. The function $E_{b,\lambda} = E_{b,\lambda}(T, \lambda)$ is given by *Planck's law*

$$\frac{E_{b,\lambda}(T, \lambda)}{n^2 T^5} = \frac{c_1 (\lambda T)^{-5}}{e^{c_2/\lambda T} - 1} \tag{5-102}$$

where $c_1 = 2\pi hc^2$ and $c_2 = hc/k$ are defined as Planck's first and second constants, respectively.

Integration of Eq. (5-102) over all wavelengths yields the *Stefan-Boltzmann law* for the hemispherical blackbody emissive power

$$E_b(T) = \int_{\lambda=0}^{\infty} E_{b,\lambda}(T, \lambda) d\lambda = n^2 \sigma T^4 \tag{5-103}$$

*In the literature the emissive power is variously called the *emittance*, *total hemispherical intensity*, or *radiant flux density*.

where $\sigma = c_1(\pi/c_2)^4/15$ is the Stephan-Boltzmann constant. Since a blackbody is an *isotropic emitter,* it follows that the intensity of blackbody emission is given by the simple formula $I_b = E_b/\pi = n^2\sigma T^4/\pi$. The intensity of radiation emitted over all wavelengths by a blackbody is thus uniquely determined by its temperature. In this presentation, all references to hemispherical emissive power shall be to the *blackbody* emissive power, and the subscript *b* may be suppressed for expediency.

For short wavelengths $\lambda T \to 0$, the asymptotic form of Eq. (5-102) is known as the *Wien equation*

$$\frac{E_{b,\lambda}(T, \lambda)}{n^2 T^5} \cong c_1 (\lambda T)^{-5} e^{-c_2/\lambda T} \tag{5-104}$$

The error introduced by use of the Wien equation is less than 1 percent when $\lambda T < 3000\ \mu m \cdot K$. The Wien equation has significant practical value in optical pyrometry for $T < 4600$ K when a red filter ($\lambda = 0.65\ \mu m$) is employed. The long-wavelength asymptotic approximation for Eq. (5-102) is known as the *Rayleigh-Jeans formula,* which is accurate to within 1 percent for $\lambda T > 778{,}000\ \mu m \cdot K$. The Raleigh-Jeans formula is of limited engineering utility since a blackbody emits over 99.9 percent of its total energy below the value of $\lambda T = 53{,}000\ \mu m \cdot K$.

The blackbody fractional energy *distribution function* is defined by

$$F_b(\lambda T) = \frac{\int_{\lambda=0}^{\lambda} E_{b,\lambda}(T, \lambda) d\lambda}{\int_{\lambda=0}^{\infty} E_{b,\lambda}(T, \lambda) d\lambda} \tag{5-105}$$

The function $F_b(\lambda T)$ defines the fraction of total energy in the blackbody spectrum which lies below $\lambda T$ and is a unique function of $\lambda T$. For purposes of digital computation, the following series expansion for $F_b(\lambda T)$ proves especially useful.

$$F_b(\lambda T) = \frac{15}{\pi^4} \sum_{k=1}^{\infty} \frac{e^{-k\xi}}{k} \left( \xi^3 + \frac{3\xi^2}{k} + \frac{6\xi}{k^2} + \frac{6}{k^3} \right) \quad \text{where} \quad \xi = \frac{c_2}{\lambda T} \tag{5-106}$$

Equation (5-106) converges rapidly and is due to Lowan (1941) as referenced in Chang and Rhee [*Int. Comm. Heat Mass Transfer*, **11:** 451–455 (1984)].

Numerically, in the preceding, $h = 6.6260693 \times 10^{-34}$ J·s is the Planck constant; $c = 2.99792458 \times 10^8$ m/s is the velocity of light in vacuum; and $k = 1.3806505 \times 10^{-23}$ J/K is the Boltzmann constant. These data lead to the following values of Planck's first and second constants: $c_1 = 3.741771 \times 10^{-16}$ $W \cdot m^2$ and $c_2 = 1.438775 \times 10^{-2}$ m·K, respectively. Numerical values of the Stephan-Boltzmann constant $\sigma$ in several systems of units are as follows: $5.67040 \times 10^{-8}$ $W/(m^2 \cdot K^4)$; $1.3544 \times 10^{-12}$ $cal/(cm^2 \cdot s \cdot K^4)$; $4.8757 \times 10^{-8}$ $kcal/(m^2 \cdot h \cdot K^4)$; $9.9862 \times 10^{-9}$ $CHU/(ft^2 \cdot h \cdot K^4)$; and $0.17123 \times 10^{-8}$ $Btu/(ft^2 \cdot h \cdot °R^4)$ (CHU = Celsius heat unit; 1.0 CHU = 1.8 Btu).

**Blackbody Displacement Laws** The blackbody energy spectrum is plotted *logarithmically* in Fig. 5-7 as

$$\frac{E_{b,\lambda}(\lambda T)}{n^2 T^5} \times 10^{13} \frac{\text{W}}{\text{m}^2 \cdot \mu\text{m} \cdot \text{K}^5}$$

versus $\lambda T\ \mu m \cdot K$. For comparison, a companion inset is provided in cartesian coordinates. The upper abscissa of Fig. 5-7 also shows the blackbody energy distribution function $F_b(\lambda T)$. Figure 5-7 indicates that the wavelength-temperature product for which the maximum intensity occurs is $\lambda_{max} T = 2898\ \mu m \cdot K$. This relationship is known as *Wien's displacement law,* which indicates that the wavelength for maximum intensity is *inversely* proportional to the absolute temperature. Blackbody displacement laws are useful in engineering practice to estimate wavelength intervals appropriate to relevant system temperatures. The Wien displacement law can be misleading, however, because the wavelength for maximum intensity depends on whether the intensity is defined in terms of frequency or wavelength interval. Two additional useful displacement laws are defined in terms of either the value of $\lambda T$ corresponding to the maximum energy per unit *fractional change* in wavelength or frequency, that is, $\lambda T = 3670\ \mu m \cdot K$, or to the value of $\lambda T$ corresponding to one-half of the blackbody energy, that is, $\lambda T = 4107\ \mu m \cdot K$. Approximately one-half of the blackbody energy lies within the twofold $\lambda T$ range *geometrically centered* on $\lambda T = 3670\ \mu m \cdot K$, that is, $3670/\sqrt{2} < \lambda T < 3670\sqrt{2}\ \mu m \cdot K$. Some 95 percent of the blackbody energy lies in the interval $1662.6 < \lambda T < 16{,}295\ \mu m \cdot K$. It thus follows that for the temperature range between ambient (300 K) and flame temperatures (2000 K or 3140°F), wavelengths of engineering heat-transfer importance are *bounded* between 0.83 and 54.3 μm.

## Nomenclature and Units—Radiative Transfer

| | |
|---|---|
| $a$, $a_g$, $a_{g,1}$ | WSGG spectral model clear plus gray weighting constants |
| $\overline{C}_p$, $\overline{C}_{p,\text{Prod}}$ | Heat capacity per unit mass, $J \cdot kg^{-1} \cdot K^{-1}$ |
| $\overline{ij} = \overline{s_i s}_j$ | Shorthand notation for direct exchange area |
| $A$, $A_i$ | Area of enclosure or zone $i$, $m^2$ |
| $c$ | Speed of light in vacuum, m/s |
| $c_1$, $c_2$ | Planck's first and second constants, $W \cdot m^2$ and $m \cdot K$ |
| $d_p$, $r_p$ | Particle diameter and radius, μm |
| $E_{b\lambda} = E_{b\lambda}(T, \lambda)$ | Monochromatic, blackbody emissive power, $W/(m^2 \cdot \mu m)$ |
| $E_n(x)$ | Exponential integral of order $n$, where $n = 1, 2, 3, \ldots$ |
| $E$ | Hemispherical emissive power, $W/m^2$ |
| $E_b = n^2 \sigma T^4$ | Hemispherical blackbody emissive power, $W/m^2$ |
| $f_v$ | Volumetric fraction of soot |
| $f_b(\lambda T)$ | Blackbody fractional energy distribution |
| $\overline{F}_{i,j}$ | Direct view factor from surface zone $i$ to surface zone $j$ |
| $\overline{\overline{F}}_{i,j}$ | Refractory augmented black view factor; $F$-bar |
| $\mathfrak{F}_{i,j}$ | Total view factor from surface zone $i$ to surface zone $j$ |
| $h$ | Planck's constant, $J \cdot s$ |
| $h_i$ | Heat-transfer coefficient, $W/(m^2 \cdot K)$ |
| $H_i$ | Incident flux density for surface zone $i$, $W/m^2$ |
| $H$ | Enthalpy rate, W |
| $\dot{H}_F$ | Enthalpy feed rate, W |
| $I_\lambda \equiv I_\lambda(\vec{r}, \vec{\Omega}, \lambda)$ | Monochromatic radiation intensity, $W/(m^2 \cdot \mu m \cdot sr)$ |
| $k$ | Boltzmann's constant, J/K |
| $k_{\lambda,p}$ | Monochromatic line absorption coefficient, $(atm \cdot m)^{-1}$ |
| $K$ | Gas absorption coefficient, $m^{-1}$ |
| $L_M$, $L_{M0}$ | Average and optically thin mean beam lengths, m |
| $\dot{m}$ | Mass flow rate, $kg/h^{-1}$ |
| $n$ | Index of refraction |
| $M$, $N$ | Number of surface and volume zones in enclosure |
| $MS$, $MF$ | Number of source/sink and flux zones in enclosure where $M = MS + MF$ |
| $p_k$ | Partial pressure of species $k$, atm |
| $P$ | Number of WSGG gray gas spectral windows |
| $Q_i$ | Total radiative flux originating at surface zone $i$, W |
| $Q_{i,j}$ | Net radiative flux between zone $i$ and zone $j$, W |
| $T$ | Temperature, K |
| $U$ | Overall heat-transfer coefficient in WSCC model |
| $V$ | Enclosure volume, $m^3$ |
| $W$ | Leaving flux density (radiosity), $W/m^2$ |

### Greek characters

| | |
|---|---|
| $\alpha$, $\alpha_{1,2}$ | Surface absorptivity or absorptance; subscript 1 refers to the surface temperature while subscript 2 refers to the radiation source |
| $\alpha_{g,1}$, $\varepsilon_g$, $\tau_{g,1}$ | Gas absorptivity, emissivity, and transmissivity |
| $\beta$ | Dimensionless constant in mean beam length equation, $L_M = \beta \cdot L_{M0}$ |
| $\Delta T_{ge} \equiv T_g - T_e$ | Adjustable temperature fitting parameter for WSCC model, K |
| $\varepsilon$ | Gray diffuse surface emissivity |
| $\varepsilon_g(T, r)$ | Gas emissivity with path length $r$ |
| $\varepsilon_\lambda(T, \Omega, \lambda)$ | Monochromatic, unidirectional surface emissivity |
| $\eta = 1/\lambda$ | Wave number in vacuum, $cm^{-1}$ |
| $\lambda = c/\nu$ | Wavelength in vacuum, μm |
| $\nu$ | Frequency, Hz |
| $\rho = 1 - \varepsilon$ | Diffuse reflectivity |
| $\sigma$ | Stefan-Boltzmann constant, $W/(m^2 \cdot K^4)$ |
| $\Sigma$ | Number of unique direct surface-to-surface direct exchange areas |
| $\tau_g = 1 - \varepsilon_g$ | Gas transmissivity |
| $\Omega$ | Solid angle, sr (steradians) |
| $\Phi$ | Equivalence ratio of fuel and oxidant |
| $\Psi^{(3)}(x)$ | Pentagamma function of $x$ |
| $\omega$ | Albedo for single scatter |

### Dimensionless quantities

| | |
|---|---|
| $D_{\text{eff}} = \dfrac{N_{\text{FD}}}{(\overline{S_1 G}_R / A_1) + N_{\text{CR}}}$ | Effective firing density |
| $N_{CR} = \dfrac{h}{4\sigma \overline{T}^3_{g,1}}$ | Convection-radiation number |
| $N_{FD} = \dot{H}_f / \sigma T^4_{\text{Ref}} \cdot A_1$ | Dimensionless firing density |
| $\eta_g$ | Gas-side furnace efficiency |
| $\eta'_g = \eta_g(1 - \Theta_o)$ | Reduced furnace efficiency |
| $\Theta_i = T_i / T_{\text{Ref}}$ | Dimensionless temperature |

### Vector notation

| | |
|---|---|
| $\vec{\mathbf{n}}_i$ and $\vec{\mathbf{n}}_j$ | Unit vectors normal to differential area elements $dA_i$ and $dA_j$ |
| $\vec{r}$ | Position vector |
| $\vec{\Omega}$ | Arbitrary unit direction vector |

### Matrix notation

| | |
|---|---|
| $\mathbf{I}_M$ | Column vector, all of whose elements are unity $[M \times 1]$ |
| $\mathbf{I} = [\delta_{i,j}]$ | Identity matrix, where $\delta_{i,j}$ is the Kronecker delta; that is, $\delta_{i,j} = 1$ for $i = j$ and $\delta_{i,j} = 0$ for $i \neq j$ |
| $\mathbf{aI} = [a_i \cdot \delta_{i,j}]$ | Diagonal matrix of WSGG gray gas surface zone a-weighting factors $[M \times M]$ |
| $\boldsymbol{a}_g\mathbf{I} = [a_{g,i} \cdot \delta_{i,j}]$ | Diagonal matrix of gray gas WSGG volume zone a-weighting factors $[N \times N]$ |
| $\mathbf{A} = [A_{i,j}]$ | Arbitrary nonsingular square matrix |
| $\mathbf{A}^T = [A_{j,i}]$ | Transpose of $\mathbf{A}$ |
| $\mathbf{A}^{-1} = [A_{i,j}]^{-1}$ | Inverse of $\mathbf{A}$ |
| $\mathbf{DI} = [D_i \cdot \delta_{i,j}]$ | Arbitrary diagonal matrix |
| $\mathbf{DI}^{-1} = [\delta_{i,j} / D_i]$ | Inverse of diagonal matrix |
| $\mathbf{CDI} = \mathbf{CI} \cdot \mathbf{DI} = [C_i \cdot D_i \cdot \delta_{i,j}]$ | Product of two diagonal matrices |
| $\mathbf{AI} = [A_i \cdot \delta_{i,j}]$ | Diagonal matrix of surface zone areas, $m^2$ $[M \times M]$ |
| $\varepsilon\mathbf{I} = [\varepsilon_i \cdot \delta_{i,j}]$ | Diagonal matrix of diffuse zone emissivities $[M \times M]$ |
| $\rho\mathbf{I} = [\rho_i \cdot \delta_{i,j}]$ | Diagonal matrix of diffuse zone reflectivities $[M \times M]$ |
| $\mathbf{E} = [E_i] = \left[\sigma T_i^4\right]$ | Column vector of surface blackbody hemispherical emissive powers, $W/m^2$ $[M \times 1]$ |
| $\mathbf{EI} = [E_i \cdot \delta_{i,j}] = \left[\sigma T_i^4 \cdot \delta_{i,j}\right]$ | Diagonal matrix of surface blackbody emissive powers, $W/m^2$ $[M \times M]$ |
| $\mathbf{E}_g = [E_{g,i}] = \left[\sigma T_{g,i}^4\right]$ | Column vector of gas blackbody hemispherical emissive powers, $W/m^2$ $[N \times 1]$ |
| $\mathbf{E_gI} = [E_{g,i} \cdot \delta_{i,j}] = \left[\sigma T_{g,i}^4 \cdot \delta_{i,j}\right]$ | Diagonal matrix of gas blackbody emissive powers, $W/m^2$ $[N \times N]$ |
| $\mathbf{H} = [H_i]$ | Column vector of surface zone incident flux densities, $W/m^2$ $[M \times 1]$ |
| $\mathbf{W} = [W_i]$ | Column vector of surface zone leaving flux densities, $W/m^2$ $[M \times 1]$ |
| $\mathbf{Q} = [Q_i]$ | Column vector of surface zone fluxes, W $[M \times 1]$ |
| $\mathbf{R} = [\mathbf{AI} - \overline{\mathbf{ss}} \cdot \rho\mathbf{I}]^{-1}$ | Inverse multiple-reflection matrix, $m^{-2}$ $[M \times M]$ |
| $\overleftarrow{\mathbf{KI}}_\mathbf{p} = [\delta_{i,j} \cdot K_{p,i}]$ | Diagonal matrix of WSGG $K_{p,i}$ values for the $i$th zone and $p$th gray gas component, $m^{-1}$ $[N \times N]$ |
| $\overleftarrow{\mathbf{KI}}$ | Diagonal matrix of WSGG-weighted gray gas absorption coefficients, $m^{-1}$ $[N \times N]$ |
| $\mathbf{S}'$ | Column vector for net volume absorption, W $[N \times 1]$ |
| $\overline{\mathbf{ss}} = [\overline{s_i s}_j]$ | Array of direct surface-to-surface exchange areas, $m^2$ $[M \times M]$ |
| $\overline{\mathbf{sg}} = [\overline{s_i g}_j] = \overline{\mathbf{gs}}^T$ | Array of direct gas-to-surface exchange areas, $m^2$ $[M \times N]$ |
| $\overline{\mathbf{gg}} = [\overline{g_i g}_j]$ | Array of direct gas-to-gas exchange areas, $m^2$ $[N \times N]$ |
| $\overline{\mathbf{SS}} = [\overline{S_i S}_j]$ | Array of total surface-to-surface exchange areas, $m^2$ $[M \times M]$ |
| $\overline{\mathbf{SG}} = [\overline{S_i G}_j]$ | Array of total gas-to-surface exchange areas, $m^2$ $[M \times N]$ |
| $\overline{\mathbf{GS}} = \overline{\mathbf{GS}}^T$ | Array of total surface-to-gas exchange areas, $m^2$ $[N \times M]$ |
| $\overline{\mathbf{GG}} = [\overline{G_i G}_j]$ | Array of total gas-to-gas exchange areas, $m^2$ $[N \times N]$ |
| $\overleftarrow{\mathbf{SS}} = [\overleftarrow{S_i S}_j]$ | Array of directed surface-to-surface exchange areas, $m^2$ $[M \times M]$ |
| $\overleftarrow{\mathbf{SG}} = [\overleftarrow{S_i G}_j]$ | Array of directed gas-to-surface exchange areas, $m^2$ $[M \times N]$ |
| $\overleftarrow{\mathbf{GS}} \neq \overleftarrow{\mathbf{SG}}^T$ | Array of directed surface-to-gas exchange areas, $m^2$ $[N \times M]$ |
| $\overleftarrow{\mathbf{GG}} = [\overleftarrow{G_i G}_j]$ | Array of directed gas-to-gas exchange areas, $m^2$ $[N \times N]$ |
| $\mathbf{VI} = [V_i \cdot \delta_{i,j}]$ | Diagonal matrix of zone volumes, $m^3$ $[N \times N]$ |
| $\overline{\mathbf{FSQ}}$ | Array of flux fractions in SSR model, dimensionless $MS \times MS$ |
| $\overline{\mathbf{SSb}} = [\overline{\text{SS}}\text{b}_{i,j}]$ | Array of total refractory-aided exchange areas for black source/sink zones in SSR model, $m^2$ $MS \times MS$ |
| $\overline{\mathbf{SSR}} = [\overline{\text{SSR}}_{i,j}]$ | Array of total refractory-aided exchange areas for nonblack source/sink zones in SSR model, $m^2$ $MS \times MS$ |

### Subscripts

| | |
|---|---|
| $b$ | Blackbody or denotes a black surface zone |
| $f$ | Flux surface zone |
| $h$ | Hemispherical surface emissivity |
| $i, j$ | Zone number indices |
| $n$ | Normal component of surface emissivity |
| $p$ | Index for $p$th gray gas window |
| $r$ | Refractory surface zone |
| $s$ | Source-sink surface zone |
| $\lambda$ | Monochromatic variable |
| Ref | Reference quantity |

### Abbreviations

| | |
|---|---|
| CFD | Computational fluid dynamics |
| DEA, TEA | Direct exchange area and total exchange area |
| DO, FV | Discrete ordinate and finite volume methods |
| EM | Electromagnetic |
| RTE | Radiative transfer equation; equation of transfer |
| LPFF | Long plug flow furnace |
| SSR | Source-sink refractory |
| WSCC | Well-stirred combustion chamber |
| WSGG | Weighted sum of gray gases |

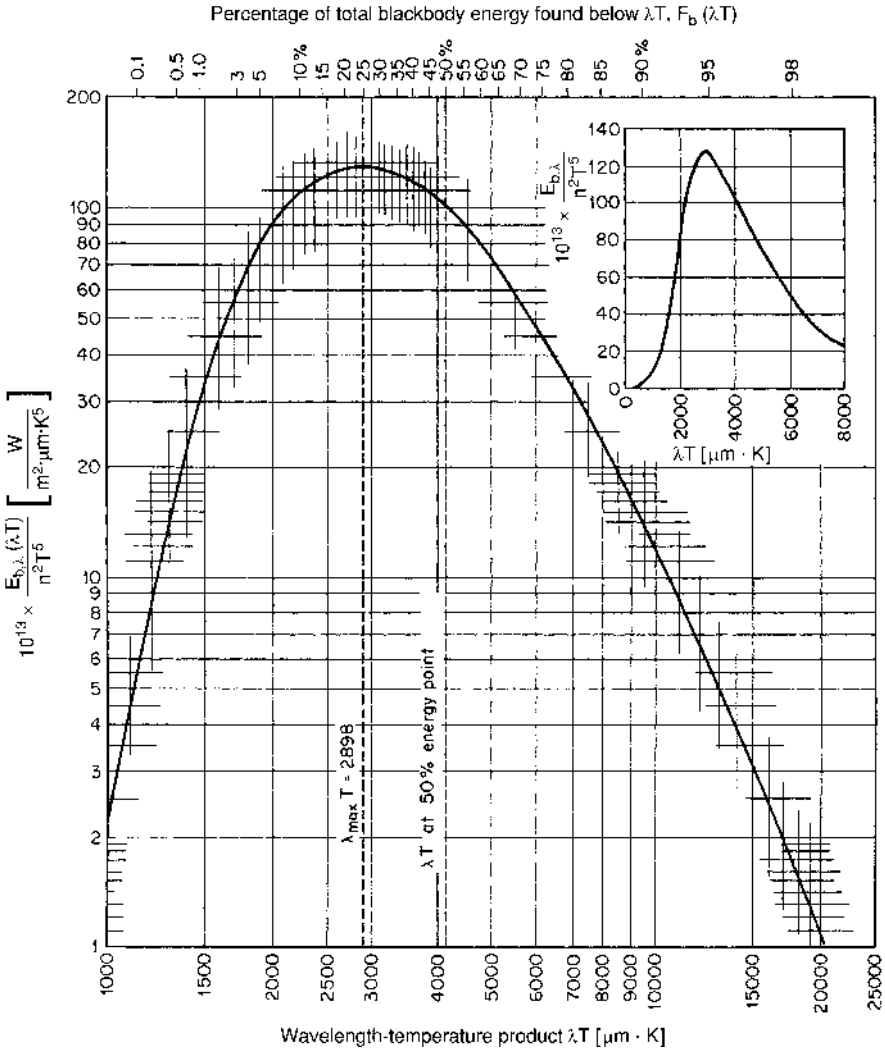

**FIG. 5-7** Spectral dependence of monochromatic blackbody hemispherical emissive power.

## RADIATIVE PROPERTIES OF OPAQUE SURFACES

**Emittance and Absorptance** The ratio of the total radiating power of any surface to that of a black surface at the same temperature is called the *emittance* or *emissivity* ε of the surface.* In general, the monochromatic emissivity is a function of temperature, direction, and wavelength, that is, $\varepsilon_\lambda = \varepsilon_\lambda(T, \bar{\Omega}, \lambda)$. The subscripts *n* and *h* are sometimes used to denote the normal and hemispherical values, respectively, of the emittance or emissivity. If radiation is incident on a surface, the fraction absorbed is called the *absorptance* (*absorptivity*). Two subscripts are usually appended to the absorptance $\alpha_{1,2}$ to distinguish between the temperature of the absorbing surface $T_1$ and the spectral energy distribution of the emitting surface $T_2$. According to *Kirchhoff's law*, the emissivity and absorptivity of a surface exposed to surroundings at its own temperature are the same for both monochromatic and total radiation. When the temperatures of the surface and its surroundings differ, the total emissivity and absorptivity of the surface are often found to be unequal; but because the absorptivity is substantially independent of irradiation density, the monochromatic emissivity and absorptivity of surfaces are equal for all practical purposes. The difference between *total* emissivity and absorptivity depends on the variation of $\varepsilon_\lambda$ with wavelength and on the difference between the temperature of the surface and the effective temperature of the surroundings.

Consider radiative exchange between a real surface of area $A_1$ at temperature $T_1$ with black surroundings at temperature $T_2$. The *net* radiant interchange is given by

$$Q_{1,2} = A_1 \int_{\lambda=0}^{\infty} [\varepsilon_\lambda(T_1,\lambda) \cdot E_{b\lambda}(T_1,\lambda) - \alpha_\lambda(T_1,\lambda) \cdot E_{b\lambda}(T_2,\lambda)] d\lambda \qquad (5\text{-}107a)$$

or

$$Q_{1,2} = A_1 \left(\varepsilon_1 \sigma T_1^4 - \alpha_{1,2} \sigma T_2^4\right) \qquad (5\text{-}107b)$$

where

$$\varepsilon_1(T_1) = \int_{\lambda=0}^{\infty} \varepsilon_\lambda(T_1,\lambda) \cdot \frac{E_{b\lambda}(T_1,\lambda)}{E_b(T_1)} d\lambda \qquad (5\text{-}108)$$

and since

$$\alpha_\lambda(T,\lambda) = \varepsilon_\lambda(T,\lambda)$$

$$\alpha_{1,2}(T_1,T_2) = \int_{\lambda=0}^{\infty} \varepsilon_\lambda(T_1,\lambda) \cdot \frac{E_{b\lambda}(T_2,\lambda)}{E_b(T_2)} d\lambda \qquad (5\text{-}109)$$

*In the literature, *emittance* and *emissivity* are often used interchangeably. NIST (the National Institute of Standards and Technology) recommends use of the suffix *-ivity* for pure materials with optically smooth surfaces, and *-ance* for rough and contaminated surfaces. Most real engineering materials fall into the latter category.

For a *gray surface* $\varepsilon_1 = \alpha_{1,2} = \varepsilon_\lambda$. A *selective surface* is one for which $\varepsilon_\lambda(T, \lambda)$ exhibits a strong dependence on wavelength. If the wavelength dependence is *monotonic*, it follows from Eqs. (5-107) to (5-109) that $\varepsilon_1$ and $\alpha_{1,2}$ can differ markedly when $T_1$ and $T_2$ are widely separated. For example, in solar energy applications, the nominal temperature of the earth is $T_1 = 294$ K, and the sun may be represented as a blackbody with radiation temperature $T_2 = 5800$ K. For these temperature conditions, a *white paint* can exhibit $\varepsilon_1 = 0.9$ and $\alpha_{1,2} = 0.1$ to 0.2. In contrast, a *thin layer of copper oxide on bright aluminum* can exhibit $\varepsilon_1$ as low as 0.12 and $\alpha_{1,2}$ greater than 0.9.

The effect of radiation source temperature on low-temperature absorptivity for a number of representative materials is shown in Fig. 5-8. Polished aluminum (curve 15) and anodized (surface-oxidized) aluminum (curve 13) are representative of metals and nonmetals, respectively. Figure 5-8 thus demonstrates the generalization that metals and nonmetals respond *in opposite directions* with regard to changes in the radiation source temperature. Since the effective solar temperature is 5800 K (10,440°R), the extreme right-hand side of Fig. 5-8 provides surface absorptivity data relevant to solar energy applications. The dependence of emittance and absorptance on the real and imaginary components of the refractive index and on the geometric structure of the surface layer is quite complex. However, a number of generalizations concerning the radiative properties of opaque surfaces are possible. These are summarized in the following discussion.

***Polished Metals***

1. In the infrared region, the magnitude of the monochromatic emissivity $\varepsilon_\lambda$ is small and is dependent on free-electron contributions. Emissivity is also a function of the ratio of resistivity to wavelength $r/\lambda$, as depicted in Fig. 5-9. At shorter wavelengths, bound-electron contributions become significant, $\varepsilon_\lambda$ is larger in magnitude, and it sometimes exhibits a maximum value.

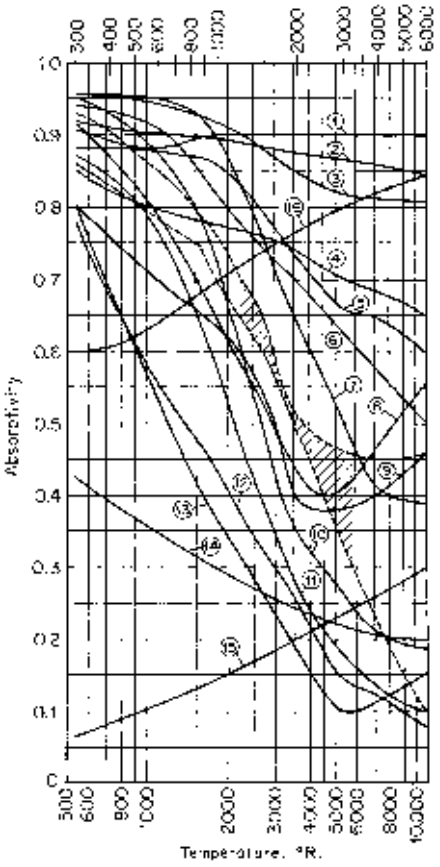

**FIG. 5-8** Variation of absorptivity with temperature of radiation source. (1) Slate composition roofing. (2) Linoleum, red brown. (3) Asbestos slate. (4) Soft rubber, gray. (5) Concrete. (6) Porcelain. (7) Vitreous enamel, white. (8) Red brick. (9) Cork. (10) White Dutch tile. (11) White chamotte. (12) MgO, evaporated. (13) Anodized aluminum. (14) Aluminum paint. (15) Polished aluminum. (16) Graphite. The two dashed lines bound the limits of data on gray paving brick, asbestos paper, wood, various cloths, plaster of Paris, lithopone, and paper. To convert degrees Rankine to kelvins, multiply by $(5.556)(10^{-1})$.

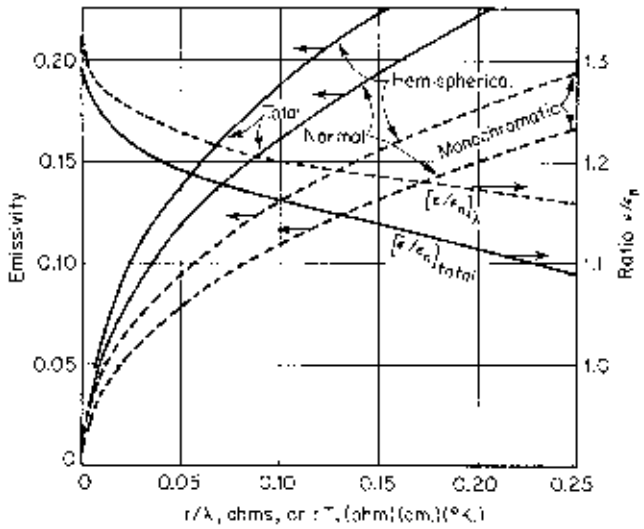

**FIG. 5-9** Hemispherical and normal emissivities of metals and their ratio. Dashed lines: monochromatic (spectral) values versus $r/\lambda$. Solid lines: total values versus $rT$. To convert ohmcentimeter-kelvins to ohm-meter-kelvins, multiply by $10^{-2}$.

In the visible spectrum, common values for $\varepsilon_\lambda$ are 0.4 to 0.8 and $\varepsilon_\lambda$ decreases slightly as temperature increases. For $0.7 < \lambda < 1.5$ μm, $\varepsilon_\lambda$ is approximately independent of temperature. For $\lambda > 8$ μm, $\varepsilon_\lambda$ is approximately proportional to the square root of temperature since $\varepsilon_\lambda \propto \sqrt{r}$ and $r \propto T$. Here the Drude or Hagen-Rubens relation applies, that is, $\varepsilon_{\lambda,n} \approx 0.0365\sqrt{r}/\lambda$, where $r$ has units of ohm-meters and $\lambda$ is measured in micrometers.

2. Total emittance is substantially proportional to absolute temperature, and at moderate temperatures $\varepsilon_n = 0.058T\sqrt{rT}$, where $T$ is measured in kelvins.

3. The total absorptance of a metal at temperature $T_1$ with respect to radiation from a black or gray source at temperature $T_2$ is equal to the emissivity evaluated at the geometric mean of $T_1$ and $T_2$. Figure 5-9 gives values of $\varepsilon_\lambda$ and $\varepsilon_{\lambda,n}$, and their ratio, as a function of the product $rT$ (solid lines). Although Fig. 5-9 is based on free-electron contributions to emissivity in the far infrared, the relations for total emissivity are remarkably good even at high temperatures. Unless extraordinary efforts are taken to prevent oxidation, a metallic surface may exhibit an emittance or absorptance which may be several times that of a polished specimen. For example, the emittance of iron and steel depends strongly on the degree of oxidation and roughness. Clean iron and steel surfaces have an emittance from 0.05 to 0.45 at ambient temperatures and from 0.4 to 0.7 at high temperatures. Oxidized and/or roughened iron and steel surfaces have values of emittance ranging from 0.6 to 0.95 at low temperatures to 0.9 to 0.95 at high temperatures.

***Refractory Materials*** For refractory materials, the dependence of emittance and absorptance on grain size and impurity concentrations is quite important.

1. Most refractory materials are characterized by $0.8 < \varepsilon_\lambda < 1.0$ for the wavelength region $2 < \lambda < 4$ μm. The monochromatic emissivity $\varepsilon_\lambda$ decreases rapidly toward shorter wavelengths for materials that are white in the visible range but demonstrates high values for black materials such as FeO and $Cr_2O_3$. Small concentrations of FeO and $Cr_2O_3$, or other colored oxides, can cause marked increases in the emittance of materials that are normally white. The sensitivity of the emittance of refractory oxides to small additions of absorbing materials is demonstrated by the results of calculations presented in Fig. 5-10. Figure 5-10 shows the emittance of a semi-infinite absorbing-scattering medium as a function of its *albedo* $\omega \equiv K_S/(K_a + K_S)$, where $K_a$ and $K_S$ are the scatter and absorption coefficients, respectively. These results are relevant to the radiative properties of fibrous materials, paints, oxide coatings, refractory materials, and other *particulate* media. They demonstrate that over the relatively small range $1 - \omega = 0.005$ to 0.1, the hemispherical emittance $\varepsilon_h$ increases from approximately 0.15 to 1.0. For refractory materials, $\varepsilon_\lambda$ varies little with temperature, with the exception of some white oxides which at high temperatures become good emitters in the visible spectrum as a consequence of the induced electronic transitions.

2. For refractory materials at ambient temperatures, the total emittance $\varepsilon$ is generally high (0.7 to 1.0). Total refractory emittance decreases

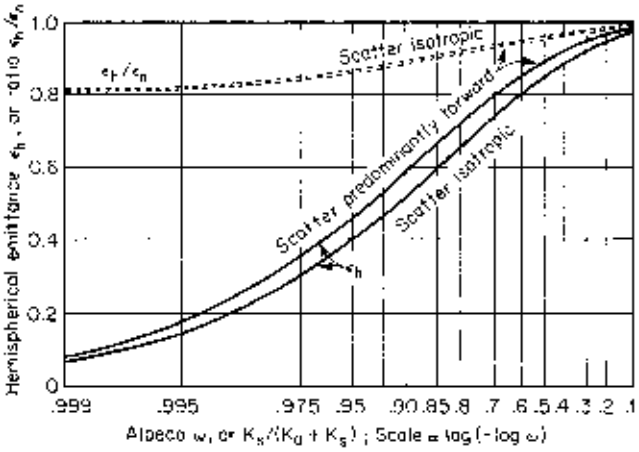

**FIG. 5-10** Hemispherical emittance $\varepsilon_h$ and the ratio of hemispherical to normal emittance $\varepsilon_h/\varepsilon_n$ for a semi-infinite absorbing-scattering medium.

with increasing temperature, such that a temperature increase from 1000 to 1570°C may result in a 20 to 30 percent reduction in ε.

3. Emittance and absorptance increase with increase in grain size over a grain size range of 1 to 200 μm.

4. The ratio $\varepsilon_h/\varepsilon_n$ of hemispherical to normal emissivity of polished surfaces varies with refractive index $n$; e.g., the ratio decreases from a value of 1.0 when $n = 1.0$ to a value of 0.93 when $n = 1.5$ (common glass) and increases back to 0.96 at $n = 3.0$.

5. As shown in Fig. 5-10, for a surface composed of particulate matter which scatters isotropically, the ratio $\varepsilon_h/\varepsilon_n$ varies from 1.0 when $\omega < 0.1$ to about 0.8 when $\omega = 0.999$.

6. The total absorptance exhibits a decrease with an increase in temperature of the radiation source similar to the decrease in emittance with an increase in the emitter temperature.

Figure 5-8 shows a regular variation of $\alpha_{1,2}$ with $T_2$. When $T_2$ is not very different from $T_1$, $\alpha_{1,2} = \varepsilon_1 (T_2/T_1)^m$. It may be shown that Eq. (5-107*b*) is then approximated by

$$Q_{1,2} = (1 + m/4)\varepsilon_{av} A_1 \sigma \left(T_1^4 - T_2^4\right) \tag{5-110}$$

where $\varepsilon_{av}$ is evaluated at the arithmetic mean of $T_1$ and $T_2$. For metals $m \approx 0.5$ while for nonmetals $m$ is small and negative.

Table 5-5 illustrates values of emittance for materials encountered in engineering practice. It is based on a critical evaluation of early emissivity data. Table 5-5 demonstrates the wide variation possible in the emissivity of a particular material due to variations in surface roughness and thermal pretreatment. With few exceptions the data in Table 5-5 refer to emittances $\varepsilon_n$ normal to the surface. The hemispherical emittance $\varepsilon_h$ is usually slightly smaller, as demonstrated by the ratio $\varepsilon_h/\varepsilon_n$ depicted in Fig. 5-10. More recent data support the range of emittance values given in Table 5-5 and their dependence on surface conditions. An extensive compilation is provided by Goldsmith, Waterman, and Hirschorn (*Thermophysical Properties of Matter*, Purdue University, Touloukian, ed., Plenum, New York, 1970–1979).

For opaque materials the reflectance ρ is the complement of the absorptance. The directional distribution of the reflected radiation depends on the material, its degree of roughness or grain size, and, if a metal, its state of oxidation. Polished surfaces of homogeneous materials are specular reflectors. In contrast, the intensity of the radiation reflected from a perfectly diffuse or *Lambert surface* is independent of direction. The directional distribution of reflectance of many oxidized metals, refractory materials, and natural products approximates that of a perfectly diffuse reflector. A better model, adequate for many calculation purposes, is achieved by assuming that the total reflectance is the sum of diffuse and specular components $\rho_D$ and $\rho_S$, as discussed in a subsequent section.

## VIEW FACTORS AND DIRECT EXCHANGE AREAS

Consider radiative interchange between two *finite* black surface area elements $A_1$ and $A_2$ separated by a transparent medium. Since they are black, the surfaces emit isotropically and totally absorb all incident radiant energy. It is desired to compute the fraction of radiant energy, per unit emissive power $E_1$, leaving $A_1$ in all directions which is intercepted and absorbed by $A_2$. The required quantity is defined as the *direct view factor* and is assigned the notation $F_{1,2}$. Since the *net radiant energy interchange* $Q_{1,2} = A_1 F_{1,2} E_1 - A_2 F_{2,1} E_2$ *between* surfaces $A_1$ and $A_2$ must be zero when their temperatures are equal, it follows thermodynamically that $A_1 F_{1,2} = A_2 F_{2,1}$. The product of area and view factor $\overline{s_1 s_2} \equiv A_1 F_{1,2}$ which has the dimensions of area is termed the *direct surface-to-surface exchange area* [DEA] for finite black surfaces. Clearly, direct exchange areas are symmetric with respect to their subscripts, that is, $\overline{s_i s_j} = \overline{s_j s_i}$, but view factors are not symmetric unless the associated surface areas are equal. This property is referred to as the *symmetry* or *reciprocity relation* for direct exchange areas. The shorthand notation $\overline{s_1 s_2} \equiv \overline{12} = \overline{21}$ for direct exchange areas is often found useful in mathematical developments.

Equation (5-101) may also be restated as

$$\frac{\partial^2 \overline{s_i s_j}}{\partial A_i \partial A_j} = \frac{\cos\varphi_i \cos\varphi_j}{\pi r^2} \tag{5-111}$$

which leads directly to the required definition of the direct exchange area as a double surface integral

$$\overline{s_i s_j} = \iint_{A_i} \iint_{A_j} \frac{\cos\varphi_i \cos\varphi_j}{\pi r^2} dA_j \, dA_i \tag{5-112}$$

All terms in Eq. (5-112) have been previously defined.

Suppose now that Eq. (5-112) is integrated over the entire confining surface of an *enclosure* which has been subdivided into $M$ finite area elements. Each of the $M$ surface *zones* must then satisfy certain *conservation relations* involving *all* the direct exchange areas in the enclosure

$$\sum_{j=1}^{M} \overline{s_i s_j} = A_i \quad \text{for } 1 \le i \le M \tag{5-113a}$$

or in terms of view factors

$$\sum_{j=1}^{M} F_{i,j} = 1 \quad \text{for } 1 \le i \le M \tag{5-113b}$$

*Contour integration* is commonly used to simplify the evaluation of Eq. (5-112) for specific geometries; see Modest (*Radiative Heat Transfer,* 3d ed., Academic Press, New York, 2013, chap. 4) or Siegel and Howell (*Thermal Radiation Heat Transfer*, 4th ed., Taylor and Francis, London, 2001, chap. 5). Two particularly useful view factors are those for perpendicular rectangles of area $XZ$ and $YZ$ with common edge $Z$ and equal parallel rectangles of area $XY$ and distance of separation $Z$. The formulae for these quantities are given as follows. For *perpendicular rectangles* with common dimension $Z$

$$(\pi \cdot X) \cdot F_{X,Y} = X \tan^{-1}\frac{1}{X} + Y \tan^{-1}\frac{1}{Y} - \sqrt{X^2+Y^2}\tan^{-1}\sqrt{\frac{1}{(X^2+Y^2)}} + \frac{1}{4}\ln\left\{\frac{(1+X^2)(1+Y^2)}{1+X^2+Y^2}\left[\frac{X^2(1+X^2+Y^2)}{(1+X^2)(X^2+Y^2)}\right]^{X^2}\left[\frac{Y^2(1+X^2+Y^2)}{(1+Y^2)(X^2+Y^2)}\right]^{Y^2}\right\} \tag{5-114a}$$

and for *parallel rectangles*, separated by distance $Z$,

$$\left(\frac{\pi \cdot X \cdot Y}{2}\right) \cdot F_{X,Y} = \frac{1}{2} \cdot \ln\left[\frac{(1+X^2)(1+Y^2)}{1+X^2+Y^2}\right] + X\sqrt{1+Y^2}\tan^{-1}\frac{X}{\sqrt{1+Y^2}} + Y\sqrt{1+X^2}\tan^{-1}\frac{Y}{\sqrt{1+X^2}} - X\tan^{-1}X - Y\tan^{-1}Y \tag{5-114b}$$

In Eqs. (5-114) $X$ and $Y$ are normalized whereby $X = x/z$ and $Y = y/z$, and the corresponding *dimensional* direct surface areas are given by $\overline{s_x s_y} = x \cdot z \cdot F_{X,Y}$ and $\overline{s_x s_y} = x\,y\,F_{X,Y}$, respectively.

The exchange area between any two area elements of a sphere is independent of their relative shape and position and is simply the product of the areas, divided by the area of the entire sphere; i.e., any spot on a sphere has equal views of all other spots.

**TABLE 5-5 Normal Total Emissivity of Various Surfaces**

A. Metals and Their Oxides

| Surface | $t$, °F* | Emissivity* | Surface | $t$, °F* | Emissivity* |
|---|---|---|---|---|---|
| Aluminum | | | Sheet steel, strong rough oxide layer | 75 | 0.80 |
| Highly polished plate, 98.3% pure | 440–1070 | 0.039–0.057 | Dense shiny oxide layer | 75 | 0.82 |
| Polished plate | 73 | 0.040 | Cast plate: | | |
| Rough plate | 78 | 0.055 | Smooth | 73 | 0.80 |
| Oxidized at 1110°F | 390–1110 | 0.11–0.19 | Rough | 73 | 0.82 |

*When two temperatures and two emissivities are given, they correspond, first to first and second to second, and linear interpolation is permissible. °C = (°F − 32)/1.8.
†Although this value is probably high, it is given for comparison with the data by the same investigator to show the effect of oil layers. See Aluminum, Part A of this table.

Figure 5-11, curves 1 through 4, shows view factors for selected parallel opposed disks, squares, and 2:1 rectangles and parallel rectangles with one infinite dimension as a function of the ratio of the smaller diameter or side to the distance of separation. Curves 2 through 4 of Fig. 5-11, for opposed rectangles, can be computed with Eq. (5-114*b*). The view factors for two finite coaxial coextensive cylinders of radii $r \le R$ and height $L$ are shown in Fig. 5-12. The direct view factors for an infinite plane parallel to a system of rows of parallel tubes are given as curves 1 and 3 of Fig. 5-13. The view factors for this two-dimensional geometry can be readily calculated by using the *crossed-strings method.*

The crossed-strings method, due to Hottel (*Radiative Transfer*, McGraw-Hill, New York, 1967), is stated as follows: "The exchange area for two-dimensional surfaces, $A_1$ and $A_2$, per unit length (in the infinite dimension) is given by the sum of the lengths of crossed strings from the ends of $A_1$ to the ends of $A_2$ less the sum of the uncrossed strings from and to the same points all divided by 2." The strings must be drawn so that all the flux from one surface to the other must cross each of a pair of crossed strings and neither of the pair of uncrossed strings. If one surface can see the other around both sides of an obstruction, two more pairs of strings are involved. The calculation procedure is demonstrated by evaluation of the tube-to-tube view factor for one row of a tube bank, as illustrated in Example 5-8.

***Example 5-8 The Crossed-Strings Method*** Figure 5-14 depicts the transverse cross section of two infinitely long, parallel circular tubes of diameter $D$ and center-to-center distance of separation $C$. Use the crossed-strings method to formulate the tube-to-tube direct exchange area and view factor, $\overline{s_t s_t}$ and $F_{t,t}$, respectively.

*Solution* The circumferential area of each tube is $A_t = \pi D$ per unit length in the infinite dimension for this two-dimensional geometry. Application of the crossed-strings procedure then yields simply

$$\overline{s_t s_t} = \frac{2(EFGH - HJ)}{2} = D \cdot [\sin^{-1}(1/R) + \sqrt{R^2} - 1 - R]$$

and

$$F_{t,t} = \overline{s_t s_t}/A_t = [\sin^{-1}(1/R) + \sqrt{R^2 - 1} - R]/\pi$$

where $EFGH$ and $HJ = C$ are the indicated line segments and $R \equiv C/D \ge 1$. Curves 1 and 5, respectively, of Fig. 5-13 can be calculated from $F_{t,t}$ with the relations $F_{p,t} = \pi \cdot (0.5 - F_{t,t})/R$ and $\bar{F}_{p,t} = F_{p,t}(2 - F_{p,t})$. Here $\bar{F}_{p,t}$ is defined as the *refractory augmented view factor* from the black plane to the black tubes, as explained in the following section on the zone method.

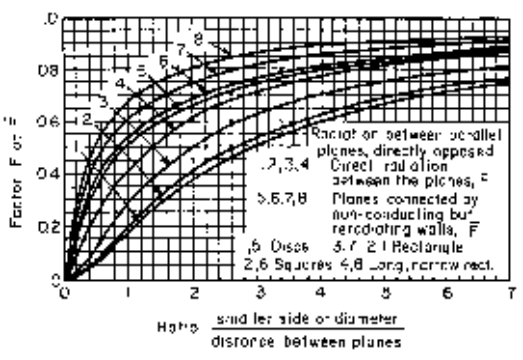

**FIG. 5-11** Radiation between parallel planes, directly opposed.

The *Yamauti principle* [Yamauti, *Res. Electrotech. Lab. (Tokyo)*, **148** (1924); **194** (1927); **250** (1929)] is stated as follows: *The exchange areas between two pairs of surfaces are equal when there is a one-to-one correspondence for all sets of symmetrically positioned pairs of differential elements in the two surface combinations.* Figure 5-15 illustrates the Yamauti principle applied to surfaces in perpendicular planes having a common edge. With reference to Fig. 5-15, the Yamauti principle states that the diagonally opposed exchange areas are equal, that is, $\overline{(1)(4)} = \overline{(2)(3)}$. Figure 5-15 also shows a more complex geometric construction for displaced cylinders for which the Yamauti principle also applies. Collectively the three terms *reciprocity* or *symmetry principle, conservation principle*, and *Yamauti principle* are referred to as *view factor or exchange area algebra.*

***Example 5-9 Illustration of Exchange Area Algebra*** Figure 5-15 shows a graphical construction depicting four perpendicular opposed rectangles with a common edge. *Numerically* evaluate the direct exchange areas and view factors for the diagonally opposed (shaded) rectangles $A_1$ and $A_4$, that is, $\overline{(1)(4)}$ as well as $\overline{(1)(3+4)}$. The dimensions of the rectangular construction are shown in Fig. 5-15 as $x = 3$, $y = 2$, and $z = 1$.

*Solution* Using shorthand notation for direct exchange areas, the conservation principle yields

$$\overline{(1+2)(3+4)} = \overline{(1+2)(3)} + \overline{(1+2)(4)} = \overline{(1)(3)} + \overline{(2)(3)} + \overline{(1)(4)} + \overline{(2)(4)}$$

Now by the Yamauti principle we have $\overline{(1)(4)} \equiv \overline{(2)(3)}$. The combination of these two relations yields the first result $\overline{(1)(4)} = \left[\overline{(1+2)(3+4)} - \overline{(1)(3)} - \overline{(2)(4)}\right]/2$. For $\overline{(1)(3+4)}$, again conservation yields $\overline{(1)(3+4)} = \overline{(1)(3)} + \overline{(1)(4)}$, and substitution of the expression

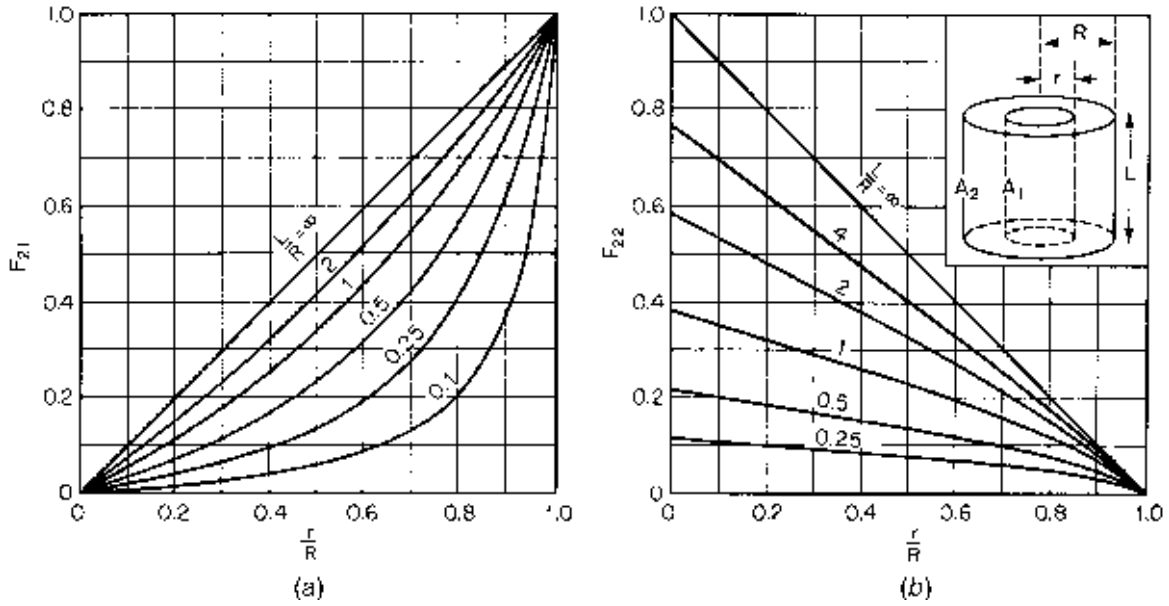

**FIG. 5-12** View factors for a system of two concentric coaxial cylinders of equal length. (*a*) Inner surface of outer cylinder to inner cylinder. (*b*) Inner surface of outer cylinder to itself.

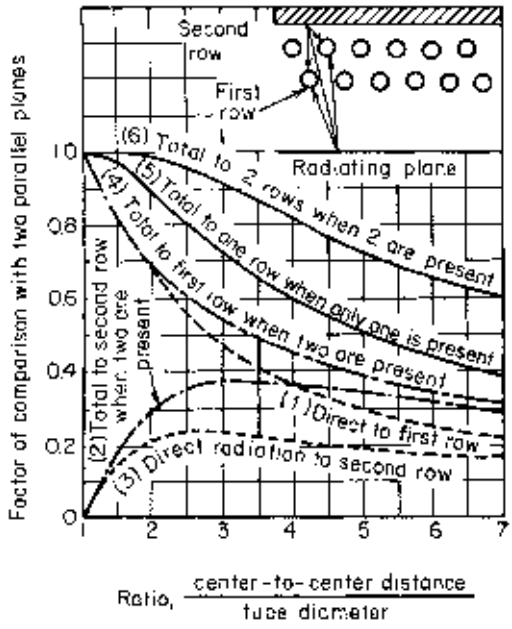

**FIG. 5-13** Distribution of radiation to rows of tubes irradiated from one side. Dashed lines: direct view factor $F$ from plane to tubes. Solid lines: total view factor $\bar{F}$ for black tubes backed by a refractory surface.

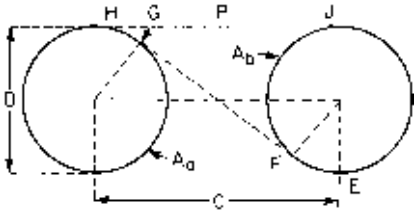

**FIG. 5-14** Direct exchange between parallel circular tubes.

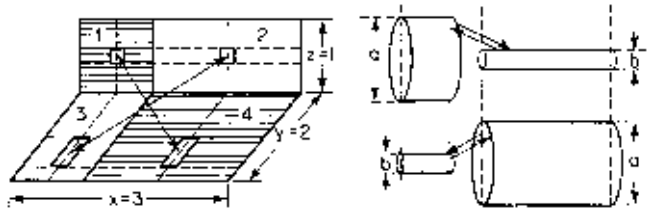

**FIG. 5-15** Illustration of the Yamauti principle.

for $\overline{(1)(4)}$ just obtained yields the second result, that is, $\overline{(1)(3+4)} = [\overline{(1+2)(3+4)} + \overline{(1)(3)} - \overline{(2)(4)}]/2.0$. All three required direct exchange areas in these two relations are readily evaluated from Eq. (5-114*a*). Moreover, these equations apply to opposed *parallel* rectangles as well as rectangles with a common edge oriented at *any angle*. Numerically it follows from Eq. (5-114*a*) for $X = 1/3$, $Y = 2/3$, and $z = 3$ that $\overline{(1+2)(3+4)} = 0.95990$; for $X = 1$, $Y = 2$, and $z = 1$ that $\overline{(1)(3)} = 0.23285$; and for $X = 1/2$, $Y = 1$, and $z = 2$ that $\overline{(2)(4)} = 0.585747$. Since $A_1 = 1.0$, this leads to

$$\overline{s_1 s_4} = F_{1,4} = (0.95990 - 0.23285 - 0.584747)/2.0 = 0.07115$$

and

$$\overline{s_1 s_{3+4}} = F_{1,3+4} = (0.95990 + 0.23285 - 0.584747)/2.0 = 0.30400$$

Many literature sources document closed-form algebraic expressions for view factors. Particularly comprehensive references include the compendia by Modest (*Radiative Heat Transfer,* 3d ed., Academic Press, New York, 2013, app. D) and Howell, Mengüç, and Siegel (*Thermal Radiative Heat Transfer,* 6th ed., CRC Press, Boca Raton, Fla., 2015, app. C). The appendices for both of these textbooks also provide a wealth of resource information for radiative transfer. Appendix F of Modest, for example, references an extensive listing of Fortran computer codes for a variety of radiation calculations which include view factors. These codes are archived in the dedicated Internet website maintained by the publisher. The textbook by Howell, Mengüç, and Siegel has also included an extensive database of view factors archived on a CD-ROM and includes a reference to an author-maintained Internet website. Other historical sources for view factors include Hottel and Sarofim (*Radiative Transfer*, McGraw-Hill, New York, 1967, chap. 2) and Hamilton and Morgan (NACA-TN 2836, December 1952).

## RADIATIVE EXCHANGE IN ENCLOSURES—THE ZONE METHOD

**Total Exchange Areas**

When an enclosure contains *reflective* surface zones, allowance must be made for not only the radiant energy transferred *directly* between any two zones but also the additional transfer attendant to *however many multiple reflections* which occur among the intervening reflective surfaces. Under such circumstances, it can be shown that the *net* radiative flux $Q_{i,j}$ between all such surface zone pairs $A_i$ and $A_j$, making full allowance for all multiple reflections, may be computed from

$$Q_{i,j} = A_i \mathcal{F}_{i,j} \sigma T_j^4 - A_j \mathcal{F}_{j,i} \sigma T_i^4 \tag{5-115a}$$

or

$$Q_{i,j} = \overline{S_i S_j} \cdot E_i - \overline{S_j S_i} \cdot E_j \tag{5-115b}$$

Here $\mathcal{F}_{i,j}$ is defined as the *total surface-to-surface view factor* from $A_i$ to $A_j$, and the quantity $\overline{S_i S_j} \equiv A_i \cdot \mathcal{F}_{i,j}$ is defined as the corresponding *total (surface-to-surface) exchange area* [TEA]. In analogy with the direct exchange areas, the total surface-to-surface exchange areas are also symmetric and thus obey reciprocity, that is, $A_i \cdot \mathcal{F}_{i,j} = A_j \cdot \mathcal{F}_{j,i}$ or $\overline{S_i S_j} = \overline{S_j S_i}$. When applied to an enclosure, *total* exchange areas and *total* view factors also must satisfy appropriate conservation relations. Total exchange areas are functions of the *geometry and radiative properties of the entire enclosure.* They are also independent of temperature if all surfaces and any radiatively participating media are gray. The following subsection presents a general *matrix method* for the *explicit* evaluation of total exchange areas from direct exchange areas and other enclosure parameters.

In what follows, conventional matrix notation is strictly employed as in $\mathbf{A} = [A_{i,j}]$ wherein the scalar subscripts always denote the row and column indices, respectively, and all *matrix entities* defined here are denoted by **boldface** notation. Section 3 of this handbook, "Mathematics," provides an especially convenient reference for introductory matrix algebra and matrix computations.

**General Matrix Formulation** The *zone method* is perhaps the simplest numerical quadrature of the governing *integral equations* for radiative transfer. It may be derived from first principles by starting with the *equation of transfer* for radiation intensity. The zone method *always conserves radiant energy* since the spatial discretization utilizes macroscopic energy balances involving *spatially averaged* radiative flux quantities. Because large sets of linear algebraic equations can arise in this process, *matrix algebra* provides the most compact notation and the most expeditious methods of solution. The mathematical approach presented here is a matrix generalization of the original (*scalar*) development of the zone method due to Hottel and Sarofim (*Radiative Transfer*, McGraw-Hill, New York, 1967). The present matrix development is abstracted from that introduced by Noble [Noble, J. J., *Int. J. Heat Mass Transfer*, **18:** 261–269 (1975)].

Consider an arbitrary three-dimensional enclosure of total volume $V$ and surface area $A$ which confines an absorbing-emitting medium (gas). Let the enclosure be subdivided (zoned) into $M$ finite surface area $A_i$ and $N$ finite volume elements $V_j$, each small enough that all such *zones* are substantially isothermal. The mathematical development in this section is then restricted by the following conditions and/or assumptions:

1. The gas temperatures are given a priori.
2. Allowance is made for gas-to-surface radiative transfer.
3. Radiative transfer with respect to the confined gas is either monochromatic or gray. The gray gas absorption coefficient is denoted here by $K[\mathrm{m}^{-1}]$. In subsequent sections the monochromatic absorption coefficient is denoted by $K_\lambda(\lambda)$.
4. All surface emissivities are assumed to be gray and thus independent of temperature.
5. Surface emission and reflection are isotropic or diffuse.
6. The gas does not scatter.

Noble [Noble, J. J., *Int. J. Heat Mass Transfer*, **18:** 261–269 (1975)] has extended the present matrix methodology to the case where the gaseous absorbing-emitting medium also *scatters isotropically*.

In matrix notation the blackbody emissive powers for all surface and volume zones comprising the zoned enclosure are designated as $\mathbf{E} = [E_i] = [\sigma T_i^4]$, an $M \times 1$ vector, and $\mathbf{E}_g = [E_{g,i}] = [\sigma T_{g,i}^4]$, an $N \times 1$ vector, respectively. Moreover, all surface zones are characterized by three $M \times M$ diagonal matrices for surface zone areas $\mathbf{AI} = [A_i \cdot \delta_{i,j}]$, diffuse emissivity $\boldsymbol{\varepsilon}\mathbf{I} = [\varepsilon_i \cdot \delta_{i,j}]$, and diffuse reflectivity, $\boldsymbol{\rho}\mathbf{I} = [(1 - \varepsilon_i) \cdot \delta_{i,j}]$, respectively. Here $\delta_{i,j}$ is the *Kronecker delta* (that is, $\delta_{i,j} = 1$ for $i = j$ and $\delta_{i,j} = 0$ for $i \neq j$).

Two arrays of direct exchange areas are now defined; i.e., the matrix $\overline{\mathbf{ss}} = [\overline{s_i s_j}]$ is the $M \times M$ array of *direct surface-to-surface exchange areas,* and the matrix $\overline{\mathbf{sg}} = [\overline{s_i g_j}]$ is the $M \times N$ array of *direct gas-to-surface exchange areas.* Here the scalar elements of $\overline{\mathbf{ss}}$ and $\overline{\mathbf{sg}}$ are computed from the integrals

$$\overline{s_i s_j} = \iint_{A_i} \iint_{A_j} \frac{e^{-Kr}}{\pi r^2} \cos\phi_i \cos\phi_j \, dA_j \, dA_i \tag{5-116a}$$

and

$$\overline{s_i g_j} = \iint_{A_i} \iiint_{V_j} K \frac{e^{-Kr}}{\pi r^2} \cos\phi_i \, dV_j \, dA_i \tag{5-116b}$$

Equation (5-116*a*) is a generalization of Eq. (5-112) for the case $K \neq 0$ while $\overline{s_i g_j}$ is a new quantity, which arises *only* for the case $K \neq 0$.

Matrix characterization of the radiative energy balance at each surface zone is then facilitated via definition of three additional $M$ vectors, namely the radiative surface flux $\mathbf{Q} = [Q_i]$, with units of watts; and the vectors $\mathbf{H} = [H_i]$ and $\mathbf{W} = [W_i]$ both having units of $\mathrm{W/m^2}$. The arrays **H** and **W** define the *incident* and *leaving* flux *densities*, respectively, at each surface zone. The variable **W** is also referred to in the literature as the *radiosity* or *exitance*. Subject to the above assumptions the zone method can be stated in three matrix equations in terms of the five vector variables **Q**, **W**, **H**, **E**, and $\mathbf{E_g}$:

$$\mathbf{W} = \boldsymbol{\varepsilon}\mathbf{I} \cdot \mathbf{E} + \boldsymbol{\rho}\mathbf{I} \cdot \mathbf{H} \tag{5-117a}$$

$$\mathbf{AI} \cdot \mathbf{H} = \overline{\mathbf{ss}} \cdot \mathbf{W} + \overline{\mathbf{sg}} \cdot \mathbf{E_g} \tag{5-117b}$$

$$\mathbf{Q} = \mathbf{AI} \cdot [\mathbf{W} - \mathbf{H}] \tag{5-117c}$$

Implementation of Eqs. (5-117) requires a priori specification of the gas (temperatures) $\mathbf{E_g}$, and $M$ other pieces of information for the surface zones. Elimination of **W** between Eqs. (5-117*a*) and (5-117*c*) followed by elimination of **H** then leads to two alternative forms for the surface flux vector **Q**:

$$\mathbf{Q} = \boldsymbol{\varepsilon}\mathbf{AI} \cdot [\mathbf{E} - \mathbf{H}] = \boldsymbol{\rho}\mathbf{I}^{-1} \cdot \boldsymbol{\varepsilon}\mathbf{AI}[\mathbf{E} - \mathbf{W}] \quad \text{for } \rho_i \neq 0 \tag{5-117d,e}$$

**Explicit Matrix Solution for Total Exchange Areas** For gray or monochromatic transfer, the *primary working relation* for zoning calculations via the matrix method is

$$\mathbf{Q} = \boldsymbol{\varepsilon}\mathbf{AI} \cdot \mathbf{E} - \overline{\mathbf{SS}} \cdot \mathbf{E} - \overline{\mathbf{SG}} \cdot \mathbf{E_g} \qquad [M \times 1] \tag{5-118}$$

Equation (5-118) makes full allowance for multiple reflections in an enclosure of any degree of complexity. To apply Eq. (5-118) for design or simulation purposes, the gas temperatures must be known and surface boundary conditions must be specified for each and every surface zone in the form of *either* $E_i$ or $Q_i$. In application of Eq. (5-118), *physically impossible values* of $E_i$ may well result if *physically unrealistic* values of $Q_i$ are specified.

In Eq. (5-118), $\overline{\mathbf{SS}}$ and $\overline{\mathbf{SG}}$ are defined as the *required* arrays of *total surface-to-surface exchange areas* and *total gas-to-surface exchange areas,* respectively. The matrices for total exchange areas are calculated *explicitly* from the

corresponding arrays of direct exchange areas and the other enclosure parameters by the following matrix formulas:

Surface-to-surface exchange $\quad \overline{\mathbf{SS}} = \boldsymbol{\varepsilon}\mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{R} \cdot \overline{\mathbf{ss}} \cdot \boldsymbol{\varepsilon}\mathbf{I} \qquad [M \times M] \qquad (5\text{-}118a)$

Gas-to-surface exchange $\quad \overline{\mathbf{SG}} = \boldsymbol{\varepsilon}\mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{R} \cdot \overline{\mathbf{sg}} \qquad [M \times N] \qquad (5\text{-}118b)$

where in Eqs. (5-118*a* and *b*), **R** is the explicit *inverse reflectivity* or *multiple reflection matrix,* defined as

$$\mathbf{R} = \left[\mathbf{AI} - \overline{\mathbf{ss}} \cdot \boldsymbol{\rho}\mathbf{I}\right]^{-1} \qquad [M \times M] \qquad (5\text{-}118c)$$

While the **R** matrix is generally not symmetric, the matrix product $\boldsymbol{\rho}\mathbf{I} \cdot \mathbf{R}$ is *always* symmetric. This fact proves useful for error checking.

The most computationally significant aspect of the matrix method is that the inverse reflectivity matrix **R** *always exists* for any physically meaningful enclosure problem. More precisely, **R** always exists provided that $K \neq 0$. Moreover, for a transparent medium, **R** exists provided that there *formally* exists at least one surface zone $A_i$ such that $\varepsilon_i \neq 0$. An important computational corollary of this statement for *transparent media* is that the matrix $[\mathbf{AI} - \overline{\mathbf{ss}}]$ is *always singular* and demonstrates *matrix rank* $M-1$ [Noble, J. J., *Int. J. Heat Mass Transfer*, **18:** 261–269 (1975)].

Finally, the four matrix arrays $\overline{\mathbf{ss}}$, $\overline{\mathbf{sg}}$, $\overline{\mathbf{SS}}$, and $\overline{\mathbf{SG}}$ of direct and total exchange areas must satisfy *matrix conservation relations* (row sums), i.e.,

Direct exchange areas $\quad \mathbf{AI} \cdot \mathbf{1}_M = \overline{\mathbf{ss}} \cdot \mathbf{1}_M + \overline{\mathbf{sg}} \cdot \mathbf{1}_N \qquad (5\text{-}119a)$

Total exchange areas $\quad \boldsymbol{\varepsilon}\mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{1}_M = \overline{\mathbf{SS}} \cdot \mathbf{1}_M + \overline{\mathbf{SG}} \cdot \mathbf{1}_N \qquad (5\text{-}119b)$

Here $\mathbf{1}_M$ is an $M \times 1$ column vector all of whose elements are unity. If $\boldsymbol{\varepsilon}\mathbf{I} = \mathbf{I}$ or equivalently, $\boldsymbol{\rho}\mathbf{I} = 0$, then Eq. (5-118*c*) reduces to $\mathbf{R} = \overline{\mathbf{AI}}^{-1}$ with the result that Eqs. (5-118*a*) and (5-118*b*) degenerate to simply $\overline{\mathbf{SS}} = \overline{\mathbf{ss}}$ and $\overline{\mathbf{SS}} = \overline{\mathbf{sg}}$, respectively. Further, while the array $\overline{\mathbf{SS}}$ is always symmetric, the array $\overline{\mathbf{SG}}$ is generally not square.

For purposes of digital computation, it is good practice to enter all data for direct exchange surface-to-surface areas $\overline{\mathbf{ss}}$ with a precision of *at least* five significant figures. This need arises because all the scalar elements of $\overline{\mathbf{sg}}$ can be calculated *arithmetically* from appropriate direct surface-to-surface exchange areas by using view factor algebra rather than via the definition of the defining integral, Eq. (5-116*b*). This process often involves small arithmetic differences between two numbers of nearly equal magnitudes, and numerical significance is easily lost.

Computer implementation of matrix methods proves straightforward, given the availability of modern software applications. In particular, several especially user-friendly GUI mathematical utilities are available that perform matrix computations using *essentially algebraic notation.* Many simple zoning problems may be solved with spreadsheets. For large $M$ and $N$, matrix methodology can involve management of a large amount of data. Error checks based on symmetry and conservation by calculation of the row sums of the four arrays of direct and total exchange areas then prove indispensable.

**Zone Methodology and Conventions** For a transparent medium, no more than $\Sigma = M(M-1)/2$ of the $M^2$ elements of the $\overline{\mathbf{ss}}$ array are *unique.* Further, surface zones are characterized into two generic types. *Source-sink zones* are defined as those for which temperature is specified and whose radiative flux $Q_i$ is to be determined. For *flux zones,* conversely, these conditions are reversed. When both types of zone are present in an enclosure, Eq. (5-118) may be *partitioned* to produce a more efficient computational algorithm. Let $M = MS + MF$ represent the total number of surface zones where *MS* is the number of source-sink zones and *MF* is the number of flux zones. The flux zones are the *last to be numbered.* Equation (5-118) is then partitioned as follows:

$$\begin{bmatrix}\mathbf{Q}_1\\ \mathbf{Q}_2\end{bmatrix} = \begin{bmatrix}\boldsymbol{\varepsilon}\mathbf{AI}_{1,1} & \mathbf{0}\\ \mathbf{0} & \boldsymbol{\varepsilon}\mathbf{AI}_{2,2}\end{bmatrix} \cdot \begin{bmatrix}\mathbf{E}_1\\ \mathbf{E}_2\end{bmatrix} - \begin{bmatrix}\overline{\mathbf{SS}}_{1,1} & \overline{\mathbf{SS}}_{1,2}\\ \overline{\mathbf{SS}}_{2,1} & \overline{\mathbf{SS}}_{2,2}\end{bmatrix} \cdot \begin{bmatrix}\mathbf{E}_1\\ \mathbf{E}_2\end{bmatrix} - \begin{bmatrix}\overline{\mathbf{SG}}_1\\ \overline{\mathbf{SG}}_2\end{bmatrix} \cdot \mathbf{E}_g \qquad (5\text{-}120)$$

Here the dimensions of the submatrices $\boldsymbol{\varepsilon}\mathbf{AI}_{1,1}$ and $\overline{\mathbf{SS}}_{1,1}$ are both $MS \times MS$ and $\overline{\mathbf{SG}}_1$ has dimensions $MS \times N$, where $N$ is the number of volume zones. Partition algebra then yields the following two matrix equations for $\mathbf{Q}_1$, the $MS \times 1$ vector of unknown source-sink fluxes, and $\mathbf{E}_2$, the $MF \times 1$ vector of unknown emissive powers for the flux zones, i.e.,

$$\mathbf{E}_2 = \left[\boldsymbol{\varepsilon}\mathbf{AI}_{2,2} - \overline{\mathbf{SS}}_{2,2}\right]^{-1} \cdot \left[\overline{\mathbf{SS}}_{2,1} \cdot \mathbf{E}_1 + \overline{\mathbf{SG}}_2 \cdot \mathbf{E}_g + \mathbf{Q}_2\right] \qquad (5\text{-}120a)$$

$$\mathbf{Q}_1 = \boldsymbol{\varepsilon}\mathbf{AI}_{1,1} \cdot \mathbf{E}_1 - \overline{\mathbf{SS}}_{1,1} \cdot \mathbf{E}_1 - \overline{\mathbf{SS}}_{1,2} \cdot \mathbf{E}_2 - \overline{\mathbf{SG}}_1 \cdot \mathbf{E}_g \qquad (5\text{-}120b)$$

The inverse matrix in Eq. (5-120*a*) formally does not exist if there is at least one flux zone such that $\varepsilon_i = 0$. However, well-behaved results are usually obtained with Eq. (5-120*a*) by utilizing a *notional zero*, say, $\varepsilon_i \approx 10^{-5}$, to simulate $\varepsilon_i = 0$. Computationally, $\mathbf{E}_2$ is first obtained from Eq. (5-120*a*) and then substituted into either Eq. (5-120*b*) or Eq. (5-118).

Surface zones need not be *contiguous.* For example, in a symmetric enclosure, zones on opposite sides of the plane of symmetry may be "lumped" into a single zone for computational purposes. Lumping nonsymmetrical zones is also possible as long as the zone temperatures and emissivities are equal.

An *adiabatic refractory surface* with surface area $A_R$ and emissivity $\varepsilon_R$, for which $Q_R = 0$, proves quite important in practice. A nearly radiatively adiabatic refractory surface occurs when differences between internal conduction and convection and external heat losses through the refractory wall are small compared with the *magnitude* of the *incident* and *leaving* radiation fluxes. Mathematically, sufficient conditions to model an adiabatic refractory surface are the a priori requirements $Q_R = 0$ for $0 < \varepsilon_R \leq 1$ or simply $\varepsilon_R = 0$. Formally, these two conditions imply somewhat different mathematical consequences. First, from Eqs. (5-117) we may write $Q_R = A_R(W_R - H_R) = \varepsilon_R A_R(E_R - H_R)$ such that the requirement $Q_R = 0$ directly implies $E_R = W_R = H_R$. Alternatively, if one specifies $\varepsilon_R = 0$, it follows from the definition of radiosity that $W_R = H_R$ and thus $Q_R \equiv 0$. In this case the value of $E_R$ is not defined and is found to be *entirely immaterial* to the enclosure calculations. Indeed all the total exchange areas for an adiabatic refractory vanish, to wit $\overline{S_i S_R} = 0$ for all $1 \leq i \leq M$. Thus the value of $E_R$ never even enters the zoning equations. Nonetheless when $\varepsilon_R = 0$, it is customary to use $E_R = W_R = H_R$ to estimate refractory temperatures. A surface zone for which $\varepsilon_R = 0$ is termed a *perfect diffuse mirror.* An adiabatic surface zone is thus also a perfect diffuse mirror. As will be shown, matrix methods automatically deal with *all* options for *flux* and adiabatic refractory surfaces.

Consider an enclosure with a single (lumped) refractory where $\varepsilon_R \neq 0$ and $M_R = 1$ and any number of source/sink and volume zones. The (scalar) refractory emissive power may be calculated from Eq. (5-120*a*) as a weighted sum of all *other known blackbody emissive powers* which characterize the enclosure, i.e.,

$$E_R = \frac{\sum_{j=1}^{M} \overline{S_R S}_j \cdot E_j + \sum_{k=1}^{N} \overline{S_R G}_k \cdot E_{g,k} + Q_R}{\sum_{j=1}^{M} \overline{S_R S}_j + \sum_{k=1}^{N} \overline{S_R G}_k} \quad \text{with } j \neq R \text{ and } \varepsilon_R \neq 0 \qquad (5\text{-}121)$$

Equation (5-121) specifically *includes* those zones which may not have a *direct* view of the refractory. When $Q_R = 0$, the refractory surface is said to be in *radiative equilibrium* with the entire enclosure. Again, note that Eq. (5-121) is indeterminate if $\varepsilon_R = 0$.

**The Limiting Case of a Transparent Medium** For the special case of a transparent medium for which $K = 0$, many practical engineering applications can be modeled with the zone method. These include combustion-fired muffle furnaces and electrical resistance furnaces. When $K \to 0$, $\overline{\mathbf{sg}} \to \mathbf{0}$ and $\overline{\mathbf{SG}} \to \mathbf{0}$. Equations (5-118) through (5-119) then reduce to three simple matrix relations

$$\mathbf{Q} = \boldsymbol{\varepsilon}\mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{E} - \overline{\mathbf{SS}} \cdot \mathbf{E} \qquad (5\text{-}122a)$$

$$\overline{\mathbf{SS}} = \boldsymbol{\varepsilon}\mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{R} \cdot \overline{\mathbf{ss}} \cdot \boldsymbol{\varepsilon}\mathbf{I} \qquad (5\text{-}122b)$$

with again

$$\mathbf{R} = [\mathbf{AI} - \overline{\mathbf{ss}} \cdot \boldsymbol{\varepsilon}\mathbf{I}]^{-1} \qquad (5\text{-}122c)$$

The radiant surface flux vector **Q,** as computed from Eq. (5-122*a*), *always* satisfies the (scalar) conservation condition $\sum_{i=1}^{M} Q_i = 0$ [or $\mathbf{1}_M^{\mathrm{T}} \cdot \mathbf{Q} = \mathbf{0}$] which is a statement of the overall *radiant* energy balance. The matrix conservation relations also simplify to

$$\mathbf{AI} \cdot \mathbf{1}_M = \overline{\mathbf{ss}} \cdot \mathbf{I}_M \qquad (5\text{-}123a)$$

and $$\boldsymbol{\varepsilon I}\cdot\mathbf{AI}\cdot\mathbf{1_M}=\overline{\mathbf{SS}}\cdot\mathbf{1_M} \tag{5-123b}$$

And the $M\times M$ arrays for *all* the direct and total view factors can be readily computed from

$$\mathbf{F}=\mathbf{AI}^{-1}\cdot\overline{\mathbf{ss}} \tag{5-124a}$$

and $$\boldsymbol{\mathcal{F}}=\mathbf{AI}^{-1}\cdot\overline{\mathbf{SS}} \tag{5-124b}$$

where the following matrix conservation relations must also be satisfied

$$\mathbf{F}\cdot\mathbf{1_M}=\mathbf{1_M} \tag{5-125a}$$

and $$\boldsymbol{\mathcal{F}}\cdot\mathbf{1_M}=\boldsymbol{\varepsilon I}\cdot\mathbf{1_M} \tag{5-125b}$$

**The Two-Zone Enclosure** Figure 5-16 depicts four simple enclosure geometries which are particularly useful for engineering calculations characterized by only *two* surface zones. For $M=2$, the reflectivity matrix $\mathbf{R}$ is readily evaluated in *closed form* since an explicit algebraic inversion formula is available for a $2\times 2$ matrix. In this case knowledge of only $\Sigma=1$ direct exchange area is required. Direct evaluation of Eqs. (5-122) then leads to

$$\overline{\mathbf{SS}}=\begin{bmatrix}\varepsilon_1A_1-\overline{S_1S_2} & \overline{S_1S_2}\\ \overline{S_1S_2} & \varepsilon_2A_2-\overline{S_1S_2}\end{bmatrix} \tag{5-126}$$

where

$$\overline{S_1S_2}=\frac{1}{\left(\dfrac{\rho_1}{\varepsilon_1A_1}+\dfrac{\rho_2}{\varepsilon_2A_2}+\dfrac{1}{\overline{s_1s_2}}\right)} \tag{5-127}$$

Equation (5-127) is of general utility for any two-zone system for which $\varepsilon_i\neq 0$.

The total exchange areas for the four geometries shown in Fig. 5-16 follow directly from Eqs. (5-126) and (5-127).

1. A planar surface $A_1$ is completely surrounded by a second surface $A_2>A_1$. Here $F_{1,1}=0,\ F_{1,2}=1,$ and $\overline{s_1s_2}=A_1$ result in

$$\overline{\mathbf{SS}}=\begin{bmatrix}\varepsilon_1\rho A_1^2+\varepsilon_2\rho_1A_1A_2 & \varepsilon_1\varepsilon_2A_1A_2\\ \varepsilon_1\varepsilon_2A_1A_2 & \varepsilon_2A_2^2+\varepsilon_1(\rho_2-\varepsilon_2)A_1A_2\end{bmatrix}\Big/[\varepsilon_1\rho_2A_1+\varepsilon_2A_2]$$

and in particular $$\overline{S_1S_2}=\frac{A_1}{1/\varepsilon_1+(A_1/A_2)\cdot(\rho_2/\varepsilon_2)} \tag{5-127a}$$

In the limiting case, where $A_1$ has no negative curvature and is completely surrounded by a very much larger surface $A_2$ such that $A_1\ll A_2$, Eq. (5-127*a*) leads to the even simpler result that $\overline{S_1S_2}=\varepsilon_1A_1$. This simple result has widespread engineering utility.

2. Two parallel plates of equal area are large compared to their distance of separation (infinite parallel plates). Case 2 is a limiting form of case 1 with $A_1=A_2$. Algebraic manipulation then results in

$$\overline{\mathbf{SS}}=\begin{bmatrix}(\varepsilon_1+\varepsilon_2-2\varepsilon_1\varepsilon_2)\cdot A_1 & \varepsilon_1\varepsilon_2A_1\\ \varepsilon_1\varepsilon_2A_1 & (\varepsilon_1+\varepsilon_2-2\varepsilon_1\varepsilon_2)A_1\end{bmatrix}\Big/[\varepsilon_1+\varepsilon_2+\varepsilon_1\varepsilon_2]$$

and in particular

$$\overline{S_1S_2}=\frac{A_1}{1/\varepsilon_1+1/\varepsilon_2-1} \tag{5-127b}$$

3. Concentric spheres or cylinders where $A_2>A_1$. Case 3 is mathematically identical to case 1.

4. A *speckled enclosure* has two surface zones. Here $\mathbf{F}=\dfrac{1}{A_1+A_2}\begin{bmatrix}A_1 & A_2\\ A_1 & A_2\end{bmatrix}$ such that $\overline{\mathbf{ss}}=\dfrac{1}{A_1+A_2}\begin{bmatrix}A_1^2 & A_1A_2\\ A_1A_2 & A_2^2\end{bmatrix}$ and Eqs. (5-126) and (5-127) then produce

$$\overline{\mathbf{SS}}=\begin{bmatrix}\varepsilon_1^2A_1^2 & \varepsilon_1\varepsilon_2A_1A_2\\ \varepsilon_1\varepsilon_2A_1A_2 & \varepsilon_2^2A_2^2\end{bmatrix}\Big/[\varepsilon_1A_1+\varepsilon_2A_2]$$

with the particular result

$$\overline{S_1S_2}=\frac{1}{1/(\varepsilon_1A_1)+1/(\varepsilon_2A_2)} \tag{5-127c}$$

Physically, a two-zone speckled enclosure is characterized by the fact that the view factor from any point on the enclosure surface to the sink zone is identical to that from any other point on the bounding surface. This is only possible when the two zones are "intimately mixed." The seemingly simplistic concept of a speckled enclosure provides a surprisingly useful *default option* in engineering calculations when the *actual* enclosure geometries are quite complex.

**The Generalized Source/Sink Refractory (SSR) Model $M\geq 3$** The major numerical effort involved in implementation of the zone method is the evaluation of the inverse multiple reflection matrix $\mathbf{R}$. For $M=3$, explicit closed-form algebraic formulas *do indeed exist* for the nine scalar elements of the inverse of any arbitrary nonsingular matrix. These formulas are so algebraically complex, however, that it generally proves impractical to present universal closed-form expressions for the total exchange areas, as has been done for the case $M=2$. For $M=3$, a notable exception, which is amenable to hand calculation, is an enclosure comprised of two source/sink zones and one flux zone. Here this method is called the *classical SSR model* and requires inversion of one $2\times 2$ matrix. The generalization of this method to multizone enclosures with $M\geq 3$ follows.

| Case 1 | Case 2 | Case 3 | Case 4 |
|---|---|---|---|
|  |  |  |  |
| A planar surface $A_1$ completely surrounded by a second surface $A_2 > A_1$. | Two infinite parallel plates where $A_1 = A_2$. | Concentric spheres or infinite cylinders where $A_1 < A_2$. Identical to Case 1. | A speckled enclosure with two surface zones. |
| $\mathbf{F}=\begin{bmatrix}0 & 1\\ A_1/A_2 & 1-A_1/A_2\end{bmatrix}$ | $\mathbf{F}=\begin{bmatrix}0 & 1\\ 1 & 0\end{bmatrix}$ | $\mathbf{F}=\begin{bmatrix}0 & 1\\ A_1/A_2 & 1-A_1/A_2\end{bmatrix}$ | $\mathbf{F}=\dfrac{1}{(A_1+A_2)}\begin{bmatrix}A_1 & A_2\\ A_1 & A_2\end{bmatrix}$ |

**FIG. 5-16** Four enclosure geometries characterized by two surface zones and one volume zone. (*Marks' Standard Handbook for Mechanical Engineers*, McGraw-Hill, New York, 1999, p. 4-73, Table 4.3.5).

Consider an arbitrary multizone enclosure that confines a transparent medium. The bounding surface is comprised of *MS* source/sink and *MF* flux zones such that $M = MS + MF$. The *MS* source/sink zones are numbered first, and *MF* flux zones are numbered last. We then partition the zoning equations exactly per the conventions employed in Eqs. (5-120).

Assume now that all the surface source/sink zones are black and all the flux zones are adiabatic. The partitioned flux equations for this simple black enclosure are then given as

$$\begin{bmatrix} \mathbf{Q}_1 \\ \mathbf{0} \end{bmatrix} = \begin{bmatrix} \mathbf{AI}_{1,1} & \mathbf{0} \\ \mathbf{0} & \mathbf{AI}_{2,2} \end{bmatrix} \cdot \begin{bmatrix} \mathbf{E}_1 \\ \mathbf{E}_2 \end{bmatrix} - \begin{bmatrix} \overline{\mathbf{ss}}_{1,1} & \overline{\mathbf{ss}}_{1,2} \\ \overline{\mathbf{ss}}_{2,1} & \overline{\mathbf{ss}}_{2,2} \end{bmatrix} \cdot \begin{bmatrix} \mathbf{E}_1 \\ \mathbf{E}_2 \end{bmatrix} \tag{5-128a}$$

and the solution to Eq. (5-128*a*) then readily follows as

$$\mathbf{Q}_1 = \left[ \mathbf{AI}_{1,1} - \overline{\mathbf{SS}}\mathbf{b} \right] \cdot \mathbf{E}_1 \tag{5-128b}$$

where
$$\overline{\mathbf{SS}}\mathbf{b} = \overline{\mathbf{ss}}_{1,1} + \overline{\mathbf{ss}}_{1,2} \cdot \mathbf{R22} \cdot \overline{\mathbf{ss}}_{2,1} \tag{5-128c}$$

and
$$\mathbf{R22} = \left[ \mathbf{AI}_{2,2} - \overline{\mathbf{ss}}_{2,2} \right]^{-1} \tag{5-128d}$$

Equation (5-128*c*) states that $\overline{\mathbf{SS}}\mathbf{b}$ is the sum of the direct radiation between all black source/sink zones plus radiation absorbed and reemitted (*reflected*) from all the adiabatic flux zones.

It then may be shown that if the source/sink zones are nonblack

$$\mathbf{Q}_1 = \boldsymbol{\varepsilon}\mathbf{AI}_1 \cdot \mathbf{E}_1 - \overline{\mathbf{SSR}} \cdot \mathbf{E}_1 - \overline{\mathbf{FSQ}} \cdot \mathbf{Q}_2 \tag{5-129a}$$

where $\overline{\mathbf{SSR}}$ and $\overline{\mathbf{FSQ}}$ are specialized total exchange areas defined as follows

$$\overline{\mathbf{SSR}} = \boldsymbol{\varepsilon}\mathbf{AI}_{1,1} \cdot \mathbf{R11b} \cdot \overline{\mathbf{SS}}\mathbf{b} \cdot \boldsymbol{\varepsilon}\mathbf{I}_{1,1} \tag{5-129b}$$

$$\overline{\mathbf{FSQ}} = \boldsymbol{\varepsilon}\mathbf{AI}_{1,1} \cdot \mathbf{R11b} \cdot \overline{\mathbf{ss}}_{1,2} \cdot \mathbf{R22} \tag{5-129c}$$

with
$$\mathbf{R11b} = \left[ \mathbf{AI}_{1,1} - \overline{\mathbf{SS}}\mathbf{b} \cdot \boldsymbol{\rho}\mathbf{I}_{1,1} \right]^{-1} \tag{5-129d}$$

which satisfy the following conservation relations

$$\overline{\mathbf{SS}}\mathbf{b} \cdot \mathbf{1}_{\mathbf{MS}} = \mathbf{AI}_{1,1} \cdot \mathbf{1}_{\mathbf{MS}} \tag{5-130e}$$

$$\overline{\mathbf{SSR}} \cdot \mathbf{1}_{\mathbf{MS}} = \boldsymbol{\varepsilon}\mathbf{AI}_{1,1} \cdot \mathbf{1}_{\mathbf{MS}} \tag{5-130f}$$

$$\overline{\mathbf{FSQ}}^{\mathbf{T}} \cdot \mathbf{1}_{\mathbf{MS}} = \mathbf{1}_{\mathbf{MF}} \tag{5-130g}$$

The solution sequence for all the enclosure surface vectors then follows as

$$\begin{aligned} \mathbf{W}_1 &= \mathbf{E}_1 - \boldsymbol{\rho}\mathbf{I}_{1,1} \cdot \boldsymbol{\varepsilon}\mathbf{AI}_{1,1}^{-1} \cdot \mathbf{Q}_1 \\ \mathbf{W}_2 &= \mathbf{R22} \cdot \left[ \overline{\mathbf{ss}}_{2,1} \cdot \mathbf{W}_1 + \mathbf{Q}_2 \right] \\ \mathbf{W} &= \begin{bmatrix} \mathbf{W}_1 \\ \mathbf{W}_1 \end{bmatrix} \qquad \mathbf{Q} = \begin{bmatrix} \mathbf{Q}_1 \\ \mathbf{Q}_2 \end{bmatrix} \\ \mathbf{H} &= \mathbf{W} - \mathbf{AI}^{-1} \cdot \mathbf{Q} \\ \mathbf{E}_2 &= \mathbf{W}_2 + \boldsymbol{\rho}\mathbf{I}_{2,2} \cdot \boldsymbol{\varepsilon}\mathbf{AI}_{2,2}^{-1} \cdot \mathbf{Q}_2 \qquad \varepsilon_i \neq 0 \end{aligned} \tag{5-131}$$

For the special case $\mathbf{Q}_2 = \mathbf{0}$ it may also be shown that $\mathbf{E}_2 = \overline{\mathbf{FSQ}}^{\mathbf{T}} \cdot \mathbf{E}_1$.

The terminology in Hottel and Sarofim defines $\overline{\mathbf{SS}}\mathbf{b}$ as the *refractory augmented exchange area for black source/sink zones*, and $\overline{\mathbf{SSR}}$ is termed the *refractory augmented exchange area for nonblack source/sink zones.* It is of paramount importance here to notice that Eqs. (5-131) lead to the fact that the zoning solution for **W**, **H**, and **Q** *is always independent of the emissivities of all the flux zones.* Moreover, $\mathbf{E}_2$ is also independent of $\boldsymbol{\varepsilon}\mathbf{I}_{2,2}$, provided that $\mathbf{Q}_2 = \mathbf{0}$. In other words, if all the flux zones are adiabatic refractories, then the refractory emissivity is *entirely immaterial* to the zoning calculations. One might first find this consequence counterintuitive since solution of the same problem via the conventional TEA route [Eqs. (5-120)] does indeed require a priori specification of $\boldsymbol{\varepsilon}\mathbf{I}_{2,2}$ even if $\mathbf{Q}_2 = \mathbf{0}$. Note further that in contrast to Eqs. (5-120) this procedure permits $\boldsymbol{\varepsilon}\mathbf{I}_{2,2} = \mathbf{0}$.

***The Classical Three-Zone SSR Model*** Set $M = 3$ and let zones 1 and 2 be the source/sink zones and zone 3 the flux zone with $Q_3 = 0$. Then the general expressions for $\overline{\mathbf{SSR}}$ reduce to

$$\overline{\mathbf{SSR}} = \begin{bmatrix} \varepsilon_1 A_1 - \overline{S_1 S_2} & \overline{S_1 S_2} \\ \overline{S_1 S_2} & \varepsilon_2 A_2 - \overline{S_1 S_2} \end{bmatrix} \tag{5-132}$$

where
$$\overline{S_1 S_2} = \frac{1}{\dfrac{\rho_1}{\varepsilon_1 A_1} + \dfrac{\rho_2}{\varepsilon_2 A_2} + \dfrac{1}{\overline{SSb}_{1,2}}} \tag{5-132a}$$

or
$$\mathcal{F}_{1,2} = \frac{1}{\dfrac{\rho_1}{\varepsilon_1} + \left( \dfrac{A_1}{A_2} \right) \dfrac{\rho_2}{\varepsilon_2} + \dfrac{1}{\overline{F}_{1,2}}} \tag{5-132b}$$

and
$$\overline{SSb}_{1,2} = \overline{s_1 s_2} + \frac{\overline{s_1 s_3} \cdot \overline{s_3 s_2}}{s_1 s_3 + s_2 s_3} \equiv A_1 \cdot \overline{F}_{1,2} \tag{5-132c}$$

where $\varepsilon_i \neq 0$. Notice that Eq. (5-132*a*) appears *deceptively similar* to Eq. (5-127). Moreover Eq. (5-132*c*) is the scalar analog of Eq. (5-128*c*). Further, if $s_1 s_1 = s_2 s_2 = 0$, Eq. (5-132*c*) then reduces to

$$\overline{SSb}_{1,2} = \frac{A_1 A_2 - (\overline{s_1 s_2})^2}{A_1 + A_2 - 2 \cdot \overline{s_1 s_2}} \tag{5-132d}$$

which necessitates the evaluation of only one direct exchange area. A consequence of Eq. (5-132*d*) is that the classic SSR model with $M = 3$ *cannot distinguish the shape of the refractory.*

Collectively, Eqs. (5-132) along with formulas to compute $\overline{F}_{1,2}$ (F-bar) are sometimes called the three-zone source/sink refractory model.

***Refractory Augmented Black View Factors $\overline{F}_{i,j}$*** In the older zoning literature, the following definition is employed: $\overline{SSb}_{i,j} = A_i \overline{F}_{i,j}$, where $\overline{F}_{i,j}$ is called the *refractory augmented black view factor,* or *F*-bar. This quantity is especially convenient to archive results for a particular enclosure geometry when the enclosure contains only one source/sink pair and any number of refractory zones.

The refractory augmented view factor $\overline{F}_{i,j}$ is documented for a few geometrically simple cases and can be calculated or approximated for others. If $A_1$ and $A_2$ are equal parallel disks, squares, or rectangles, connected by nonconducting but reradiating refractory surfaces, then $\overline{F}_{i,j}$ is given by Fig. 5-11 in curves 5 to 8. Let $A_1$ represent an infinite plane and $A_2$ represent one or two rows of infinite parallel tubes. If the only other surface is an adiabatic refractory surface located behind the tubes, then $\overline{F}_{2,1}$ is given by curve 5 or 6 of Fig. 5-13. The classic zoning literature thus contains a hierarchy of three distinct surface-to-surface view factors, denoted by $F_{i,j}$, $\overline{F}_{i,j}$, and $\mathcal{F}_{i,j}$.

***Accuracy of the Zone Method*** Experience has shown that despite its limitations even the simple SSR model with $M = 3$ can yield quite useful results for a host of practical engineering applications without resorting to digital computation. The error due to representation of the source and sink by single zones is often small, even if the views of the enclosure from different parts of the same zone are dissimilar, provided the surface emissivities are near unity. The error is also small if the temperature variation of the refractory is small. Any degree of accuracy can, of course, be obtained via matrix methodologies for arbitrarily large $M$ by using a digital computer. From a computational viewpoint, when $M \geq 4$, matrix methods *must be used.* Matrix methods must also be used for finer-scale calculations such as more detailed wall *temperature and flux density profiles.*

***The Electrical Network Analog*** At each surface zone, the *total* radiant flux is proportional to the difference between $E_i$ and $W_i$, as indicated by the equation $Q_i = \dfrac{\varepsilon_i A_i}{\rho_i}(E_i - W_i)$. The *net* flux between zones *i* and *j* is also given by $Q_{i,j} = \overline{s_i s}_j (W_i - W_j)$ where $Q_i = \sum_{i=1}^{M} Q_{i,j}$ for all $1 \leq i \leq M$ is the *total* heat flux leaving each zone. These relations suggest a *visual* electrical analog in which $E_i$ and $W_i$ are analogous to voltage potentials. The quantities $\varepsilon_i A_i / \rho_i$ and $\overline{s_i s}_j$ are analogous to conductances (reciprocal impedances), and $Q_i$ or $Q_{i,j}$ is analogous to electric currents. Such an electrical analog has been developed by Oppenheim [Oppenheim, A. K., *Trans. ASME*, **78:** 725–735 (1956)].

Figure 5-17 illustrates a generalized electrical network analogy for a three-zone enclosure consisting of one refractory zone and two gray zones $A_1$ and $A_2$. The potential points $E_i$ and $W_i$ are separated by conductances $\varepsilon_i A_i / \rho_i$. The emissive powers $E_1$ and $E_2$ represent potential sources or sinks, while $W_1$, $W_2$, and $W_r$ are internal node points. In this construction, the nodal point representing each surface is connected to that of every other surface it can see directly. Figure 5-17 can be used to formulate the total exchange area $\overline{S_1 S_2}$ for the SSR model virtually by inspection. The refractory zone is first characterized by a floating potential such that $E_r = W_r$. Next, the resistance for the parallel "current paths" between the internal nodes $W_1$ and $W_2$

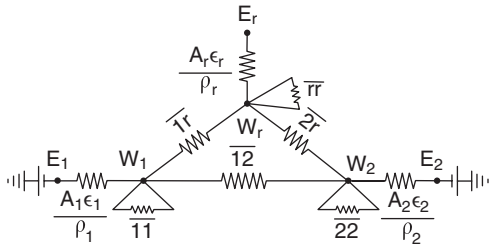

**FIG. 5-17** Generalized electrical network analog for a three-zone enclosure. Here $A_1$ and $A_2$ are gray surfaces and $A_r$ is a radiatively adiabatic surface (Hottel, H. C., and A. F. Sarofim, *Radiative Transfer*, McGraw-Hill, New York, 1967, p. 91).

is defined by $\dfrac{1}{A_1\overline{F}_{1,2}} \equiv \dfrac{1}{\overline{s_1 s_2} + 1/\left(\dfrac{1}{\overline{s_1 s_r}} + \dfrac{1}{\overline{s_2 s_r}}\right)}$ which is identical to Eq. (5-132*c*).

Finally, the overall impedance between the source $E_1$ and the sink $E_2$ is represented simply by three resistors in series and is thus given by

$$\frac{1}{\overline{S_1 S_2}} = \frac{\rho_1}{\varepsilon_1 A_1} + \frac{1}{A_1 \overline{F}_{1,2}} + \frac{\rho_2}{\varepsilon_2 A_2}$$

or

$$\overline{S_1 S_2} = \frac{1}{\dfrac{\rho_1}{\varepsilon_1 A_1} + \dfrac{\rho_2}{\varepsilon_2 A_2} + \dfrac{1}{A_1 \overline{F}_{1,2}}} \tag{5-133}$$

This result is identically the same as for the SSR model obtained previously in Eq. (5-132*a*). This equation is also valid for $M_r \geq 1$ as long as $M_b = 2$. The electrical network analog methodology can be generalized for enclosures having $M > 3$.

**Some Examples from Furnace Design** The theory of the past several subsections is best understood in the context of two engineering examples involving furnace modeling. The engineering idealization of the *equivalent gray plane concept* is introduced first. Figure 5-18 depicts a common furnace configuration in which the heating source is two refractory-backed, internally fired tube banks. Clearly the overall geometry for even this common furnace configuration is too complex to be modeled in an expeditious manner by anything other than *a simple engineering idealization*. Thus the furnace shown in Fig. 5-18 is modeled in Example 5-10, by *partitioning* the entire enclosure into two subordinate furnace compartments. First, the approach defines an imaginary gray plane $A_2$, located on the inward-facing side of the tube assemblies. Second, the total exchange area between the tubes to this *equivalent* gray plane is calculated, making full allowance for the reflection from the refractory tube backing. This plane-to-tube view factor is then *defined* to be the emissivity of the required equivalent gray plane whose temperature is further assumed to be that of the tubes. This procedure guarantees continuity of the radiant flux *into* the interior radiant portion of the furnace arising from a moderately complicated *external* source.

Example 5-10 demonstrates classical zoning calculations for radiation pyrometry in furnace applications. Example 5-11 is a classical furnace design calculation via zoning an enclosure with a *diathermanous* atmosphere and $M = 5$. The latter calculation can only be addressed with matrix methods. The results of Example 5-11 demonstrate the relative insensitivity of zoning to $M > 3$ and the engineering utility of the generalized SSR model.

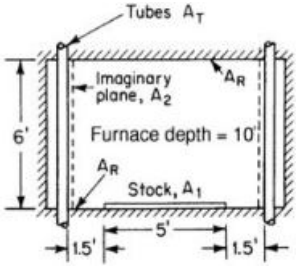

**FIG. 5-18** Furnace chamber cross section. To convert feet to meters, multiply by 0.3048.

***Example 5-10 Radiation Pyrometry*** A long tunnel furnace is heated by electrical resistance coils embedded in the ceiling. The stock travels on a floor-mounted conveyer belt and has an estimated emissivity of 0.7. The sidewalls are unheated refractories with emissivity 0.55, and the ceiling emissivity is 0.8. The furnace cross section is rectangular with height 1 m and width 2 m. A total radiation pyrometer is sighted on the walls and indicates the following apparent temperatures: ceiling 1340°C, sidewall readings average about 1145°C and the load indicates about 900°C. (*a*) What are the true temperatures of the furnace walls and stock? (*b*) What is the net heat flux at each surface and each zone pair? (*c*) Compare the adiabatic SSR and TEA matrix models.

$M = 3$ Zones
Zone 1 Source (top)
Zone 2 Sink (bottom)
Zone 3 Refractory (lumped sides)
*Physical constants:*

$$T_0 \equiv 273.15°\text{C} \qquad \sigma \equiv 5.6704 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}}$$

*Enclosure input parameters:*

$$H = 1.0\,\text{m} \qquad W = 2.0\,\text{m} \qquad L = 1.0\,\text{m}$$

*Compute direct exchange areas using crossed strings method* $\sum = 3$

$$\mathbf{ss}_4 = \begin{pmatrix} 0.0000 & 1.2361 & 0.3820 & 0.3820 \\ 1.2361 & 0.0000 & 0.3820 & 0.3820 \\ 0.3820 & 0.3820 & 0.0000 & 0.2361 \\ 0.3820 & 0.3820 & 0.2361 & 0.0000 \end{pmatrix} \text{m}^2$$

Lump the four-zone enclosure into a three-zone enclosure by combining rows and columns 3 and 4. Then

$$\overline{\mathbf{ss}} = \begin{pmatrix} \overline{s_1 s_1} & \overline{s_1 s_2} & \overline{s_1 s_3} \\ \overline{s_2 s_1} & \overline{s_2 s_2} & \overline{s_2 s_3} \\ \overline{s_3 s_1} & \overline{s_3 s_2} & \overline{s_3 s_3} \end{pmatrix} = \begin{pmatrix} 0 & 1.2361 & 0.7639 \\ 1.2361 & 0 & 0.7639 \\ 0.7639 & 0.7639 & 0.4721 \end{pmatrix} \text{m}^2$$

$$(\mathbf{AI} - \overline{\mathbf{ss}}) \cdot \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

$$\mathbf{AI} = \begin{bmatrix} A_1 & 0 & 0 \\ 0 & A_2 & 0 \\ 0 & 0 & A_3 \end{bmatrix} = \begin{bmatrix} W \cdot L & 0 & 0 \\ 0 & W \cdot L & 0 \\ 0 & 0 & 2 \cdot H \cdot L \end{bmatrix} = \begin{bmatrix} 2.0 & 0 & 0 \\ 0 & 2.0 & 0 \\ 0 & 0 & 2.0 \end{bmatrix} \text{m}^2$$

$$\boldsymbol{\varepsilon}\mathbf{I} = \begin{bmatrix} \varepsilon_1 & 0 & 0 \\ 0 & \varepsilon_2 & 0 \\ 0 & 0 & \varepsilon_3 \end{bmatrix} = \begin{bmatrix} 0.8 & 0 & 0 \\ 0 & 0.7 & 0 \\ 0 & 0 & 0.55 \end{bmatrix} \quad \boldsymbol{\rho}\mathbf{I} = \begin{bmatrix} \rho_1 & 0 & 0 \\ 0 & \rho_2 & 0 \\ 0 & 0 & \rho_3 \end{bmatrix} = \begin{bmatrix} 0.2 & 0 & 0 \\ 0 & 0.3 & 0 \\ 0 & 0 & 0.45 \end{bmatrix}$$

*Compute Radiosities* $\mathbf{W}$ *from Pyrometer Temperature Readings*

$$\mathbf{T}_\mathbf{W} = \begin{bmatrix} 1340.0 \\ 900.0 \\ 1145.0 \end{bmatrix} °\text{C} \qquad \mathbf{W} = \sigma \cdot [\mathbf{T}_\mathbf{W} + 273.15]^4 = \begin{bmatrix} 384.0 \\ 107.4 \\ 229.4 \end{bmatrix} \text{kW/m}^2$$

All matrix wall flux density quantities and heat fluxes can then be directly calculated from the radiosity (leaving flux density) vector $\mathbf{W}$.

$$\mathbf{H} = \mathbf{AI}^{-1} \cdot \overline{\mathbf{ss}} \cdot \mathbf{W} \qquad \mathbf{Q} = [\mathbf{AI} - \overline{\mathbf{ss}}] \cdot \mathbf{W} \qquad \mathbf{q} = \mathbf{AI}^{-1} \cdot \mathbf{Q} \qquad \mathbf{E} = \boldsymbol{\varepsilon}\mathbf{I}^{-1} \cdot [\mathbf{W} - \boldsymbol{\rho}\mathbf{I} \cdot \mathbf{H}]$$

leading to the final results

$$\begin{bmatrix} \text{ZONE} & \mathbf{W} & \mathbf{H} & \mathbf{q} & \mathbf{E} \\ \begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix} & \begin{pmatrix} 384.0 \\ 107.4 \\ 229.4 \end{pmatrix} & \begin{pmatrix} 154.0 \\ 324.9 \\ 241.8 \end{pmatrix} & \begin{pmatrix} 230.0 \\ -217.5 \\ -12.5 \end{pmatrix} & \begin{pmatrix} 441.5 \\ 14.2 \\ 219.1 \end{pmatrix} \end{bmatrix} \text{kW/m}^2$$

and

$$\mathbf{Q} = \begin{pmatrix} 460.0 \\ -435.0 \\ -25.0 \end{pmatrix} \text{kW}$$

Here the sidewalls act as near-adiabatic surfaces since the heat loss through each sidewall is only about 2.7 percent of the total heat flux originating at the source.
*Part (a): Actual Wall Temperatures versus Pyrometer Readings*

$$\mathbf{T} = \left[\left(\frac{\mathbf{E}}{\sigma}\right)^{0.25} - 273.15\right] = \begin{pmatrix} 1397.3 \\ 434.1 \\ 1128.9 \end{pmatrix} °\text{C} \qquad \mathbf{T}_\mathbf{W} = \begin{pmatrix} 1340.0 \\ 900.0 \\ 1145.0 \end{pmatrix} °\text{C}$$

$[k = 1, 3]$

$$\left[\varepsilon\min_k = 1 - \frac{W_k}{H_k}\right] \quad \%\mathrm{Ref}_k = \rho_k \cdot \frac{H_k}{W_k} \quad \boldsymbol{\varepsilon}_{\mathbf{min}} = \begin{pmatrix} \mathrm{NA} \\ 0.669 \\ 0.052 \end{pmatrix} \quad \mathbf{\%Ref} = \begin{pmatrix} 8.0 \\ 90.8 \\ 47.4 \end{pmatrix}$$

The (low) estimated sink emissivity, $\varepsilon_2 = 0.7$, is the dominant parameter in this example. First, the marked disparity in actual and measured sink temperature arises because the sink radiosity is comprised of 90.8 percent reflected energy, that is, $\rho_2 \cdot H_2/W_2 = 0.9075$. Moreover, when a surface flux is negative, $W < H$ and a minimum allowable surface emissivity is defined by $\varepsilon_{\min} = 1 - W/H$. Thus if the sink emissivity is less than $\varepsilon_2 = 1 - 107.4/324.9 = 0.6694$, the sink temperature becomes imaginary. Lastly if the sink were black, $E_2 = W_2 = 107.4\ \mathrm{kW/m^2}$, the pyrometer and sink temperatures would be equal with $T_2 = 900°\mathrm{C}$.

*Part (b): Radiant Heat Flux at Each Surface*

Define
$$\mathbf{WI_4} = \begin{pmatrix} 384 & 0 & 0 & 0 \\ 0 & 107.4 & 0 & 0 \\ 0 & 0 & 229.4 & 0 \\ 0 & 0 & 0 & 229.4 \end{pmatrix} \frac{\mathrm{kW}}{\mathrm{m^2}}$$

and
$$\mathbf{Q_p} = \mathbf{WI_4} \cdot \mathbf{ss_4} - \mathbf{ss_4} \cdot \mathbf{WI_4} = \begin{pmatrix} 0 & 341.9 & 59.1 & 59.1 \\ -341.9 & 0 & -46.6 & -46.6 \\ -59.1 & 46.6 & 0 & 0 \\ -59.1 & 46.6 & 0 & 0 \end{pmatrix} \mathrm{kW}$$

leading to
$$\mathbf{Q} = \mathbf{Q_p} \cdot \begin{pmatrix} 1 \\ 1 \\ 1 \\ 1 \end{pmatrix} = \begin{pmatrix} 460.0 \\ -435.0 \\ -12.5 \\ -12.5 \end{pmatrix} \mathrm{kW}$$

where $\mathbf{Q_p}$ defines the heat flux between all *zone pairs* and $\mathbf{Q}$ is the total heat flux *at* each surface.

*Part (c): Compare the Adiabatic SSR and TEA Matrix Approaches*

Both approaches require the a prioi specification of three unknowns. Here we shall assume as in part (a) that

$$E_1 = 441.5\ \frac{\mathrm{kW}}{\mathrm{m^2}} \qquad E_2 = 14.2\ \frac{\mathrm{kW}}{\mathrm{m^2}} \qquad Q_3 = 25.0\ \mathrm{kW}$$

*Compute total exchange areas*

$$\mathbf{R} \equiv [\mathbf{AI} - \overline{\mathbf{ss}} \cdot \boldsymbol{\rho}\mathbf{I}]^{-1}$$

$$\overline{\mathbf{SS}} = \boldsymbol{\varepsilon}\mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{R} \cdot \overline{\mathbf{ss}} \cdot \boldsymbol{\varepsilon}\mathbf{I} = \begin{bmatrix} 0.2948 & 0.8284 & 0.4769 \\ 0.8284 & 0.1761 & 0.3955 \\ 0.4769 & 0.3955 & 0.2277 \end{bmatrix} \qquad [\boldsymbol{\varepsilon}\mathbf{I} \cdot \mathbf{AI} - \overline{\mathbf{SS}}] \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$E_3 = \frac{(SS_{3,1} \cdot E_1 + SS_{3,2} \cdot E_2 + Q_3)}{SS_{3,1} + SS_{3,2}} = 219.10\ \frac{\mathrm{kW}}{\mathrm{m^2}} \qquad \text{see Eq. (5-121)}$$

$$\mathbf{Q}3 = (\boldsymbol{\varepsilon}\mathbf{I} \cdot \mathbf{AI} - \mathbf{SS}) \cdot \begin{pmatrix} \mathbf{E}_1 \\ \mathbf{E}_2 \\ \mathbf{E}_3 \end{pmatrix} = \begin{pmatrix} 460.0 \\ -435.0 \\ -25.0 \end{pmatrix} \mathrm{kW}$$

*Compute SSR matrix for M = 3*
$$\mathbf{AI1} = \begin{pmatrix} A_1 & 0 \\ 0 & A_2 \end{pmatrix} \qquad \boldsymbol{\varepsilon}\mathbf{I1} = \begin{pmatrix} \varepsilon_1 & 0 \\ 0 & \varepsilon_2 \end{pmatrix}$$

[Use Eqs. (5-128*a*) and (5-130).]

$$\mathrm{ssb}_{1,2} = \mathrm{ss}_{1,2} + \frac{\mathrm{ss}_{1,3} \cdot \mathrm{ss}_{3,2}}{\mathrm{ss}_{1,3} + \mathrm{ss}_{2,3}} = 1.618\ \mathrm{m^2}$$

$$\mathrm{SSR}_{1,2} = \frac{1}{\dfrac{\rho 1}{\varepsilon_1 \cdot A_1} + \dfrac{\rho 2}{\varepsilon_2 \cdot A_2} + \dfrac{1}{\mathrm{ssb}_{1,2}}} = 1.0446\ \mathrm{m^2}$$

$$\mathbf{SSR} = \begin{pmatrix} \varepsilon_1 \cdot A_1 - \mathrm{SSR}_{1,2} & \mathrm{SSR}_{1,2} \\ \mathrm{SSR}_{1,2} & \varepsilon_2 \cdot A_2 - \mathrm{SSR}_{1,2} \end{pmatrix} = \begin{pmatrix} 0.5554 & 1.0446 \\ 1.0446 & 0.3554 \end{pmatrix} \mathrm{m^2}$$

$$\begin{pmatrix} Q_1 \\ Q_2 \end{pmatrix} = (\boldsymbol{\varepsilon}\mathbf{I1} \cdot \mathbf{AI1} - \mathbf{SSR}) \cdot \begin{pmatrix} \mathrm{E}_1 \\ \mathrm{E}_2 \end{pmatrix} = \begin{pmatrix} 446.3 \\ -446.3 \end{pmatrix} \mathrm{kW}$$

Thus the adiabatic SSR model produces $Q_1 = 446.3$ kW versus the measured value of $Q_1 = 460.0$ with a discrepancy of about 3.0 percent. Mathematically the adiabatic SSR model assumes a value of $Q_3 = 0$ which precludes the sidewall heat loss of $Q_3 = -25.0\ \mathrm{kW/m^2}$. This assumption accounts for *all* the difference between the two values.

*Demonstrate relationships between SSR and TEA models*

Assume $Q_3 = 0$; then from Eq. (5-121) we have

$$E_{30} = \frac{(\mathrm{SS}_{3,1} \cdot E_1 + \mathrm{SS}_{3,2} \cdot E_2)}{\mathrm{SS}_{3,1} + \mathrm{SS}_{3,2}} = 247.8\ \frac{\mathrm{kW}}{\mathrm{m^2}} \qquad \Theta_{30} = \frac{E_{30} - E_2}{E_1 - E_2} = 0.5466$$

and we define
$$\Theta_3 = \frac{\mathrm{SS}_{3,1}}{\mathrm{SS}_{3,1} + \mathrm{SS}_{3,2}} = 0.5466$$

with the result that $\Theta_3 = \Theta_{30}$ and

$$\mathrm{SS12} = \mathrm{SS}_{1,2} + \mathrm{SS}_{2,3} \cdot \Theta_3 = 1.0446\ \mathrm{m^2}$$

Thus $\mathrm{SSR}_{1,2} = \mathrm{SS12}$ is the *refractory-aided* total exchange area between *nonblack* zones 1 and 2. Perhaps counterintuitive, this result is independent of $\varepsilon_3$. Note further that if we recompute the total exchange areas with $\varepsilon_3 = 0$ to obtain $\mathbf{SS_0}$, then **SSR** can be directly evaluated from the (upper) source/sink portion of $\mathbf{SS_0}$ as shown below.

$$\mathbf{SS_0} = \begin{pmatrix} 0.5554 & 1.0446 & 0 \\ 1.0446 & 0.3554 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

(This example was developed as a MATHCAD 15 worksheet. MATHCAD is a registered trademark of Parametric Technology Corporation.)

***Example 5-11 Furnace Simulation via Zoning*** The furnace chamber depicted in Fig. 5-18 is heated by combustion gases passing through 20 vertical radiant tubes which are backed by refractory sidewalls. The tubes have an outside diameter of $D = 5$ in (12.7 cm) mounted on $C = 12$-in (4.72-cm) centers and a gray body emissivity of 0.8. The interior (radiant) portion of the furnace is a $6 \times 8 \times 10$ ft rectangular parallelepiped with a total surface area of 376 ft$^2$ (34.932 m$^2$). A 50-ft$^2$ (4.645-m$^2$) sink with emissivity 0.9 is positioned centrally on the floor of the furnace. The tube and sink temperatures are measured with embedded thermocouples as 1500 and 1200°F, respectively. The gray refractory emissivity may be taken as 0.5. While all *other* refractories are assumed to be radiatively adiabatic, the roof of the furnace is estimated to lose heat to the surroundings with a *flux density* (W/m$^2$) equal to 5 percent of the source and sink emissive power difference. An estimate of the radiant flux arriving at the sink is required, as well as estimates for the roof and average refractory temperatures in consideration of refractory service life.

*Part (a): Equivalent Gray Plane Emissivity* Algebraically compute the equivalent gray plane emissivity for the refractory-backed tube bank idealized by the imaginary plane $A_2$, depicted in Fig. 5-18.

*Solution* Let zone 1 represent *one* tube and zone 2 represent the *effective* plane, that is, the *unit cell* for the tube bank. Then $A_1 = \pi D$ and $A_2 = C$ are the corresponding zone areas, respectively (per unit vertical dimension). Also set $\varepsilon_1 = 0.8$ with $\varepsilon_2 = 1.0$ and define $R = C/D = 12/5 = 2.4$.

For $R = 2.4$, curves 1 and 5 of Fig. 5-13 yield, respectively, $F_{p,t} = 0.57$ and $\overline{F}_{p,t} = 0.81$. Using notation consistent with Example 5-8, more accurate values are calculated as follows:

$$F_{t,t} = [\sin^{-1}(1/R) + \sqrt{R^2 - 1} - R]/\pi = 0.06733$$

$$F_{p,t} = (0.5 - F_{t,t}) \cdot \pi/R = 0.56637$$

and
$$\overline{F}_{2,1} = \overline{F}_{p,t} = F_{p,t}(1 - F_{p,t}) = 0.81196$$

To make allowance for nonblack tubes, application of Eq. (5-132*b*) with $\varepsilon_2 = 0.8$ then yields

$$\mathcal{F}_{2,1} = \frac{1}{0/1 + (2.4/\pi) \cdot (0.2/0.8) + 1/\overline{F}_{2,1}} = 0.70295$$

*Part (b): Radiant Furnace Chamber with Roof Heat Loss*

$M = 5$ zones
Zone 1 = Sink (bottom)
Zone 2 = Source (lumped sides)
Zone 3 = Refractory (roof)
Zone 4 = Refractory (lumped ends)
Zone 5 = Refractory (lumped floor strips)

*Boundary conditions:* Five pieces of information are required for $M = 5$.

$$\mathbf{T_{1F}} = \begin{pmatrix} 1200.0 \\ 1500.0 \end{pmatrix} °\mathrm{F} \qquad \mathbf{T_{1C}} = \frac{5}{9}(\mathbf{T_{1F}} - 32) = \begin{pmatrix} 648.9 \\ 815.6 \end{pmatrix} °\mathrm{C}$$

$$\mathbf{E_1} = \begin{pmatrix} E_1 \\ E_2 \end{pmatrix} = \sigma \cdot [\mathbf{T_{1C}} + 273.15]^4 = \begin{pmatrix} 40.98 \\ 79.66 \end{pmatrix} \mathrm{kW/m^2}$$

$$Q_3 = -0.5 \cdot [E_2 - E_1] \cdot A_3/10.76391 = -14.374\ \mathrm{kW} \qquad Q_4 = Q_5 = 0$$

$$\mathbf{Q_2} = \begin{pmatrix} Q_3 \\ Q_4 \\ Q_5 \end{pmatrix} = \begin{pmatrix} -14.374 \\ 0 \\ 0 \end{pmatrix} \mathrm{kW}$$

*Enclosure input parameters:*

$$\boldsymbol{\varepsilon I} = \begin{pmatrix} \boldsymbol{\varepsilon I}_{11} & \mathbf{O} \\ \mathbf{O}^{T} & \boldsymbol{\varepsilon I}_{22} \end{pmatrix} = \begin{bmatrix} \begin{pmatrix} 0.9 & 0 \\ 0 & 0.70295 \end{pmatrix} & \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \\ \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix} & \begin{pmatrix} 0.5 & 0 & 0 \\ 0 & 0.5 & 0 \\ 0 & 0 & 0.5 \end{pmatrix} \end{bmatrix}$$

$$\boldsymbol{\rho I} = \begin{pmatrix} \boldsymbol{\rho I}_{11} & \mathbf{O} \\ \mathbf{O}^{T} & \boldsymbol{\rho I}_{22} \end{pmatrix} = \begin{bmatrix} \begin{pmatrix} 0.1 & 0 \\ 0 & 0.29705 \end{pmatrix} & \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \\ \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix} & \begin{pmatrix} 0.5 & 0 & 0 \\ 0 & 0.5 & 0 \\ 0 & 0 & 0.5 \end{pmatrix} \end{bmatrix}$$

$A_1 = 50\ \text{ft}^2 \quad A_2 = 120\ \text{ft}^2 \quad A_3 = 80\ \text{ft}^2 \quad A_4 = 96\ \text{ft}^2 \quad A_5 = 30\ \text{ft}^2$

$$\mathbf{AI} = \begin{pmatrix} \mathbf{AI}_{11} & \mathbf{O} \\ \mathbf{O}^{T} & \mathbf{AI}_{22} \end{pmatrix} = \begin{bmatrix} \begin{pmatrix} 4.6452 & 0 \\ 0 & 11.1484 \end{pmatrix} & \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \\ \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix} & \begin{pmatrix} 7.4322 & 0 & 0 \\ 0 & 8.9187 & 0 \\ 0 & 0 & 2.7871 \end{pmatrix} \end{bmatrix} \text{m}^2$$

*Compute direct exchange areas:* There are $\Sigma = 10$ nonzero direct exchange areas. These are obtained from Eqs. (5-114) and view factor algebra. The final (partitioned) array of direct exchange areas is

$$\mathbf{ss} = \begin{pmatrix} \mathbf{ss}_{11} & \mathbf{ss}_{12} \\ \mathbf{ss}_{21} & \mathbf{ss}_{22} \end{pmatrix} = \begin{bmatrix} \begin{pmatrix} 0 & 1.559 \\ 1.559 & 2.0777 \end{pmatrix} & \begin{pmatrix} 1.5747 & 1.5115 & 0 \\ 2.8391 & 3.3925 & 1.2802 \end{pmatrix} \\ \begin{pmatrix} 1.5747 & 2.8391 \\ 1.5115 & 3.3925 \\ 0 & 1.2802 \end{pmatrix} & \begin{pmatrix} 0 & 2.2421 & 0.7763 \\ 2.2421 & 1.0419 & 0.7306 \\ 0.7763 & 0.7306 & 0 \end{pmatrix} \end{bmatrix} \text{m}^2$$

$$(\mathbf{AI} - \overline{\mathbf{ss}}) \cdot \begin{pmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix} \qquad \mathbf{R22} = (\mathbf{AI}_{22} - \mathbf{ss}_{22})^{-1} = \begin{pmatrix} 0.1553 & 0.0494 & 0.0562 \\ 0.0494 & 0.1459 & 0.052 \\ 0.0562 & 0.052 & 0.3881 \end{pmatrix} \frac{1}{\text{m}^2}$$

*Compute SSR total exchange areas:*

$$\mathbf{SSb} = \mathbf{ss}_{11} + \mathbf{ss}_{12} \cdot \mathbf{R22} \cdot \mathbf{ss}_{21} = \begin{pmatrix} 0.9537 & 3.6915 \\ 3.6915 & 7.4569 \end{pmatrix} \text{m}^2$$

$$\mathbf{R11b} = (\mathbf{AI}_{11} - \mathbf{SSb} \cdot \boldsymbol{\rho I}_{11})^{-1} = \begin{pmatrix} 0.222 & 0.0273 \\ 0.0092 & 0.1131 \end{pmatrix} \frac{1}{\text{m}^2}$$

$$\mathbf{SSR} = \boldsymbol{\varepsilon I}_{11} \cdot \mathbf{AI}_{11} \cdot \mathbf{R11b} \cdot \mathbf{SSb} \cdot \boldsymbol{\varepsilon I}_{11} = \begin{pmatrix} 1.1751 & 3.0055 \\ 3.0055 & 4.8312 \end{pmatrix} \text{m}^2$$

$$\mathbf{FSQ} = \boldsymbol{\varepsilon I}_{11} \cdot \mathbf{AI}_{11} \cdot \mathbf{R11b} \cdot \mathbf{SS}_{12} \cdot \mathbf{R22} = \begin{pmatrix} 0.3739 & 0.3568 & 0.2500 \\ 0.6261 & 0.6432 & 0.7500 \end{pmatrix} \text{m}^2$$

*Check row-sum conservation:*

$$(\mathbf{AI}_{11} - \mathbf{SSb}) \cdot \begin{pmatrix} 1 \\ 1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \qquad \boldsymbol{\rho I}_{11} \cdot \mathbf{R11b} - \mathbf{R11b}^{T} \cdot \boldsymbol{\rho I}_{11} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix} \frac{1}{\text{m}^2}$$

$$(\boldsymbol{\varepsilon I}_{11} \cdot \mathbf{AI}_{11} - \mathbf{SSR}) \cdot \begin{pmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix} \qquad \mathbf{FSQ}^{T} \cdot \begin{pmatrix} 1 \\ 1 \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}$$

*Compute wall fluxes and radiosity for source/sink zones:*

$$\mathbf{Q}_1 = \boldsymbol{\varepsilon I}_{11} \cdot \mathbf{AI}_{11} \cdot \mathbf{E}_1 - \mathbf{SSR} \cdot \mathbf{E}_1 - \mathbf{FSQ} \cdot \mathbf{Q}_2 = \begin{pmatrix} -110.88 \\ 125.25 \end{pmatrix} \text{kW}$$

$$\mathbf{Q} = \begin{pmatrix} \mathbf{Q}_1 \\ \mathbf{Q}_2 \end{pmatrix} = \begin{bmatrix} \begin{pmatrix} -110.88 \\ 125.25 \end{pmatrix} \\ \begin{pmatrix} -14.37 \\ 0 \\ 0 \end{pmatrix} \end{bmatrix} \text{kW} \qquad \mathbf{q} = \mathbf{AI}^{-1} \cdot \mathbf{Q} = \begin{pmatrix} -23.87 \\ 11.23 \\ -1.93 \\ 0 \\ 0 \end{pmatrix} \frac{\text{kW}}{\text{m}^2}$$

$$\mathbf{W}_1 = \mathbf{E}_1 - \boldsymbol{\rho I}_{11} \cdot (\boldsymbol{\varepsilon I}_{11} \cdot \mathbf{AI}_{11})^{-1} \cdot \mathbf{Q}_1 = \begin{pmatrix} 43.636 \\ 74.915 \end{pmatrix} \frac{\text{kW}}{\text{m}^2}$$

$$\mathbf{W}_2 = \mathbf{R22}(\mathbf{ss}_{21} \cdot \mathbf{W}_1 + \mathbf{Q}_2) = \begin{pmatrix} 62.694 \\ 64 \cdot 874 \\ 68 \cdot 879 \end{pmatrix} \frac{\text{kW}}{\text{m}^2} \qquad \mathbf{W} = \begin{pmatrix} \mathbf{W}_1 \\ \mathbf{W}_2 \end{pmatrix} = \begin{bmatrix} \begin{pmatrix} 43 \cdot 64 \\ 74.91 \end{pmatrix} \\ \begin{pmatrix} 62 \cdot 69 \\ 64 \cdot 87 \\ 68 \cdot 88 \end{pmatrix} \end{bmatrix} \frac{\text{kW}}{\text{m}^2}$$

$$\mathbf{E}_2 = \mathbf{W}_2 + \boldsymbol{\rho I}_{22} \cdot (\boldsymbol{\varepsilon I}_{22} \cdot \mathbf{AI}_{22})^{-1} \cdot \mathbf{Q}_2 = \begin{pmatrix} 60 \cdot 76 \\ 64 \cdot 87 \\ 68 \cdot 88 \end{pmatrix} \frac{\text{kW}}{\text{m}^2} \qquad \mathbf{E} = \begin{pmatrix} \mathbf{E}_1 \\ \mathbf{E}_2 \end{pmatrix} = \begin{bmatrix} \begin{pmatrix} 40 \cdot 98 \\ 79.66 \end{pmatrix} \\ \begin{pmatrix} 60 \cdot 76 \\ 64 \cdot 87 \\ 68 \cdot 88 \end{pmatrix} \end{bmatrix} \frac{\text{kW}}{\text{m}^2}$$

$$\mathbf{H} = \mathbf{AI}^{-1} \cdot \mathbf{ss} \cdot \mathbf{W} \qquad \mathbf{T}_C = (\mathbf{E}/\boldsymbol{\sigma})^{0.25} - 273.15 = \begin{bmatrix} 648.9 \\ 815.6 \\ 744.3 \\ 761.1 \\ 776.7 \end{bmatrix} ^{\circ}\text{C}$$

*Summary of computed results:*

A 5 percent roof heat loss is consistent with practical measurement errors. Sensitivity testing was also performed with $M = 3$, 4, and 5 with and without heat loss. The classic adiabatic SSR model corresponds to $M = 3$ with no roof heat loss. For $M = 4$, the ends (zone 4) and floor strips (zone 5) were lumped together into one noncontiguous refractory zone. The results are summarized in the following tables. With the exception of the temperature of the floor strips, the computed results for **Q** are seen to be remarkably insensitive to $M$.

**5% ROOF HEAT LOSS**

Computed results for **W**, **H**, **Q**, and **E** are wholly independent of refractory emissivity except the roof emissive power, $E_{3}$, because $Q_3 \neq 0$.

$$\begin{bmatrix} \text{ZONE} & \mathbf{W} & \mathbf{H} & \mathbf{Q} & \mathbf{E} \\ \begin{pmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{pmatrix} & \begin{pmatrix} 43.64 \\ 74.91 \\ 62.69 \\ 64.87 \\ 68.88 \end{pmatrix} & \begin{pmatrix} 67.50 \\ 63.68 \\ 64.63 \\ 64.87 \\ 68.88 \end{pmatrix} & \begin{pmatrix} -23.87 \\ 11.23 \\ -1.93 \\ 0 \\ 0 \end{pmatrix} & \begin{pmatrix} 40.98 \\ 79.66 \\ 60.76 \\ 64.87 \\ 68.88 \end{pmatrix} \end{bmatrix} \text{kW/m}^2 \quad \text{and} \quad \mathbf{Q} = \begin{pmatrix} -110.88 \\ 125.25 \\ -14.37 \\ 0 \\ 0 \end{pmatrix} \text{kW}$$

**ADIABATIC ROOF**

Computed results for **W**, **H**, **Q**, and **E** are wholly independent of the refractory emissivity.

$$\begin{bmatrix} \text{ZONE} & \mathbf{W} & \mathbf{H} & \mathbf{Q} & \mathbf{E} \\ \begin{pmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{pmatrix} & \begin{pmatrix} 43.76 \\ 75.26 \\ 65.20 \\ 65.86 \\ 69.99 \end{pmatrix} & \begin{pmatrix} 68.79 \\ 64.83 \\ 65.20 \\ 65.86 \\ 69.99 \end{pmatrix} & \begin{pmatrix} -25.03 \\ 10.43 \\ 0 \\ 0 \\ 0 \end{pmatrix} & \begin{pmatrix} 40.98 \\ 79.66 \\ 65.20 \\ 65.86 \\ 69.99 \end{pmatrix} \end{bmatrix} \text{kW/m}^2 \quad \text{and} \quad \mathbf{Q} = \begin{pmatrix} -116.25 \\ 116.25 \\ 0 \\ 0 \\ 0 \end{pmatrix} \text{kW}$$

*Effect of zone numbers:*

**Heat Flux Computations** [kW]

*Part (c): Auxiliary Calculations for Tube Area and Effective Tube Emissivity*
Suppose the heating tubes were totally surrounded by an enclosure at the temperature of the sink and the emissivity of the refractory. Calculate the effective emissivity of the tubes for this idealization. Make reference to Eq. (5-127*a*).

*Solution:* With $D = 5$ in and $H = 6$ ft, the total surface area of the tubes is calculated as $A_{\text{Tubes}} = 20 \cdot \pi \cdot D \cdot H = 157.1\ \text{ft}^2 = 14.59\ \text{m}^2$. Equation (5-127*a*) may be employed to yield

$$\varepsilon_{\text{Tubes}} = \frac{Q_{\text{Tubes}}}{A_{\text{Tubes}}(E_2 - E_1) - \left[\frac{1}{R}\right].\left[\frac{1-\varepsilon_{\text{Enc}}}{\varepsilon_{\text{Enc}}}\right].Q_{\text{Tubes}}}$$

where $Q_{\text{Tubes}} = Q_2 = 125.25$ km and $R = A_{\text{Enc}}/A_{\text{Tubes}} = 376/157.1 = 2.394$.

For $\varepsilon_{\text{Enc}} = 0.50$ there results $\varepsilon_{\text{Tubes}} = 0.2446$ while for a black surround

$$\varepsilon_{\text{Tubes}} = \frac{Q_2}{A_{\text{Tubes}}(E_2 - E_1)} = 0.2219$$

The insensitivity of Eq. (5-127*a*) for $R > 1$ thus demonstrates its significant engineering utility.

[This example was developed as a MATHCAD 15 worksheet. MATHCAD is a registered trademark of Parametric Technology Corporation.]

**Allowance for Specular Reflection** If the assumption that all surface zones are diffuse emitters and reflectors is relaxed, the zoning equations become much more complex. Here, all surface parameters become functions of the *angles of incidence and reflection* of the radiation beams at each surface. In practice, such details of reflectance and emission are seldom known. When they are, the Monte Carlo method of tracing a large number of beams emitted from random positions and in random initial directions is probably the best way of obtaining a solution. Howell, Mengüç, and Siegel, *Thermal Radiative Heat Transfer*, 6th ed., CRC Press, Boca Raton, Fla., 2015, chap. 7) and Modest (*Radiative Heat Transfer,* 3d ed., Academic Press, New York, 2013, chap. 21) review the utilization of the Monte Carlo approach to a variety of radiant transfer applications. Among these is the Monte Carlo calculation of direct exchange areas for very complex geometries. Monte Carlo techniques are generally *not used* in practice for simpler engineering applications.

A simple *engineering* approach to specular reflection is the *diffuse plus specular reflection model.* Here the total reflectivity $\rho_i = 1 - \varepsilon_i = \rho_{Si} + \rho_{Di}$ is represented as the sum of a *diffuse component* $\rho_{Si}$ and a *specular component* $\rho_{Di}$. The method yields analytical results for a number of two-surface zone geometries. In particular, the following equation is obtained for exchange between concentric spheres or infinitely long coaxial cylinders for which $A_1 < A_2$:

$$\overline{S_1 S_2} = \frac{A_1}{\frac{1}{\varepsilon_1} + \frac{\rho_2}{\varepsilon_2}\cdot\frac{A_1}{A_2} + \frac{\rho_{S2}}{(1-\rho_{S2})}(1 - A_1/A_2)} \tag{5-134}$$

For $\rho_{D1} = \rho_{D2} = 0$ (or equivalently $\rho_1 = \rho_{S1}$ with $\rho_2 = \rho_{S2}$), Eq. (5-134) yields the limiting case for wholly specular reflection

Specular limit
$$\overline{S_1 S_2} = \frac{A_1}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1} \tag{5-134a}$$

which is independent of the area ratio $A_1/A_2$. It is important to notice that Eq. (5-134*a*) is *similar* to Eq. (5-127*b*), but the emissivities here are defined as $\varepsilon_1 \equiv 1 - \rho_{s1}$ and $\varepsilon_2 \equiv 1 - \rho_{s2}$. When surface reflection is wholly diffuse [$\rho_{S1} = \rho_{S2} = 0$ or $\rho_1 = \rho_{D1}$ with $\rho_2 = \rho_{D2}$], Eq. (5-134) results in a formula *identical* to Eq. (5-127*a*),

*Diffuse limit*
$$\overline{S_1 S_2} = \frac{A_1}{\left[\frac{1}{\varepsilon_1} + \left(\frac{A_1}{A_2}\right)\frac{\rho_2}{\varepsilon_2}\right]} \tag{5-134b}$$

For the case of (infinite) parallel flat plates where $A_1 = A_2$, Eq. (5-134) leads to a general formula *similar* to Eq. (5-134*a*) but with the stipulation here that $\varepsilon_1 \equiv 1 - \rho_{D1} - \rho_{S1}$ and $\varepsilon_2 \equiv 1 - \rho_{D2} - \rho_{S2}$.

Another particularly interesting limit of Eq. (5-134) occurs when $A_2 >> A_1$, which might represent a small sphere irradiated by infinite surroundings which can reflect radiation originating at $A_1$ back to $A_1$. That is, even though $A_2 \to \infty$, the "self" total exchange area does not necessarily vanish, to wit

$$\overline{S_1 S_2} = \frac{\varepsilon_1^2 \cdot \rho_{s2} \cdot A_1}{1 - \rho_1 \cdot \rho_{s_2}} \quad \text{and} \quad \overline{S_1 S_2} = \frac{\varepsilon_1 (1 - \rho_{s2}) \cdot A_1}{1 - \rho_1 \cdot \rho_{s2}} \tag{5-134c,d}$$

which again exhibits diffuse and specular limits. The diffuse plus specular reflection model becomes significantly more complex for geometries with $M \geq 3$ where digital computation is usually required.

**An Exact Solution to the Integral Equations—The Hohlraum** Exact solutions of the fundamental *integral equations* for radiative transfer are available for only a few simple cases. One of these is the evaluation of the emittance from a small aperture, of area $A_1$, in the surface of an isothermal spherical cavity of radius $R$. In German, this geometry is termed a *hohlraum* for hollow space. For this special case the radiosity $W$ is constant over the inner surface of the cavity. It then follows that the ratio $W/E$ is given by

$$W/E = \frac{\varepsilon}{1 - \rho \cdot [1 - A_1/(4\pi R^2)]} \tag{5-135}$$

where $\varepsilon$ and $\rho = 1 - \varepsilon$ are the diffuse emissivity and reflectivity of the interior cavity surface, respectively. The ratio $W/E$ is the effective emittance of the aperture as sensed by an external narrow-angle receiver (radiometer) viewing the cavity interior. Assume that the cavity is constructed of a rough material whose (diffuse) emissivity is $\varepsilon = 0.5$. As a point of reference, if the cavity is to simulate a blackbody emitter to better than 98 percent of an ideal theoretical blackbody, Eq. (5-135) then predicts that the ratio of the aperture to sphere areas $A_1/(4\pi R^2)$ must be less than 2 percent. Equation (5-135) has practical utility in the experimental design of calibration standards for laboratory radiometers.

## RADIATION FROM GASES AND SUSPENDED PARTICULATE MATTER

**Introduction** Flame radiation originates as a result of emission from water vapor and carbon dioxide in the hot gaseous combustion products and from the presence of particulate matter. The latter includes emission both from burning of microscopic and submicroscopic soot particles and from large suspended particles of coal, coke, or ash. Thermal radiation owing to the presence of water vapor and carbon dioxide is not visible. The characteristic blue color of clean natural gas flames is due to chemiluminescence of the excited intermediates in the flame which contribute negligibly to the radiation from combustion products.

***Gas Emissivities*** Radiant transfer in a gaseous medium is characterized by three quantities: the gas emissivity, gas absorptivity, and gas transmissivity. *Gas emissivity* refers to radiation originating within a gas volume that is incident on some reference surface. *Gas absorptivity* and *gas transmissivity,* however, refer to the absorption and transmission of radiation from some *external* surface radiation source characterized by some radiation temperature $T_1$. The sum of the gas absorptivity and transmissivity must, by definition, be unity. Gas absorptivity may be calculated from an appropriate gas emissivity. The gas emissivity is a function of only the gas temperature $T_g$ while the absorptivity and transmissivity are functions of *both* $T_g$ and $T_1$.

The *standard hemispherical monochromatic gas emissivity* is defined as the direct volume-to-surface exchange area for a hemispherical gas volume to an infinitesimal area element located at the center of the planar base. Consider monochromatic transfer in a *black* hemispherical enclosure of radius $R$ that confines an isothermal volume of gas at temperature $T_g$. The temperature of the bounding surfaces is $T_1$. Let $A_2$ denote the area of the finite hemispherical surface and $dA_1$ denote an infinitesimal element of area located at the center of the planar base. The (dimensionless) monochromatic direct

exchange area for exchange between the finite hemispherical surface $A_2$ and $dA_1$ then follows from direct integration of Eq. (5-116*a*) as

$$\frac{\partial(\overline{s_1 s_2})_\lambda}{\partial A_1} = \int_{\varphi_1=0}^{\pi/2} \frac{e^{-K_\lambda R}}{\pi R^2} \cos\varphi_1 \, 2\pi R^2 \sin\varphi_1 \, d\varphi_1 = e^{-K_\lambda R} \tag{5-136a}$$

and from conservation there results

$$\frac{\partial(\overline{s_1 g})_\lambda}{\partial A_1} = 1 - e^{-K_\lambda R} \tag{5-136b}$$

Note that Eq. (5-136*b*) is identical to the expression for the gas emissivity for a column of path length $R$. In Eqs. (5-136) the gas absorption coefficient is a function of gas temperature, composition, and wavelength, that is, $K_\lambda = K_\lambda(T,\lambda)$. The net monochromatic radiant flux density at $dA_1$ due to irradiation from the gas volume is then given by

$$q_{1g,\lambda} = \frac{\partial(\overline{s_1 g})_\lambda}{\partial A_1}(E_{1,\lambda} - E_{g,\lambda}) \equiv \alpha_{g,1\lambda} E_{1,\lambda} - \varepsilon_{g,\lambda} E_{g,\lambda} \tag{5-137}$$

In Eq. (5-137), $\varepsilon_{g,\lambda}(T,\lambda) = 1 - \exp(-K_\lambda R)$ is defined as the monochromatic or *spectral gas emissivity* and $\alpha_{g,\lambda}(T,\lambda) = \varepsilon_{g,\lambda}(T,\lambda)$.

If Eq. (5-137) is integrated with respect to wavelength over the entire EM spectrum, an expression for the *total* flux density is obtained

$$q_{1,g} = \alpha_{g,1} E_1 - \varepsilon_g E_g \tag{5-138}$$

where

$$\varepsilon_g(T_g) = \int_{\lambda=0}^{\infty} \varepsilon_\lambda(T_{g,\lambda}) \cdot \frac{E_{b,\lambda}(T_{g,\lambda})}{E_b(T_g)} d\lambda \tag{5-138a}$$

and

$$\alpha_{g,1}(T_1, T_g) = \int_{\lambda=0}^{\infty} \alpha_{g,\lambda}(T_g,\lambda) \cdot \frac{E_{b,\lambda}(T_1,\lambda)}{E_b(T_1)} d\lambda \tag{5-138b}$$

define the *total* gas emissivity and absorptivity, respectively. The notation used here is analogous to that used for surface emissivity and absorptivity as previously defined. For a *real* gas $\varepsilon_g = \alpha_{g,1}$ only if $T_1 = T_g$, while for a *gray* gas mass of arbitrarily shaped volume $\varepsilon_g = \alpha_{g,1} = \partial(\overline{s_i g})/\partial A_1$ is independent of temperature. Because $K_\lambda(T,\lambda)$ is also a function of the composition of the radiating species, it is necessary in what follows to define a second absorption coefficient $k_{p,\lambda}$, where $K_\lambda = k_{p,\lambda} p$. Here $p$ is the partial pressure of the radiating species, and $k_{p,\lambda}$, with units of $(\text{atm}\cdot\text{m})^{-1}$, is referred to as the *monochromatic line absorption coefficient*.

***Mean Beam Lengths*** It is always possible to represent the emissivity of an arbitrarily shaped volume of gray gas (and thus the corresponding direct gas-to-surface exchange area) with an equivalent sphere of radius $R = L_M$. In this context the hemispherical radius $R = L_M$ is referred to as the *mean beam length* of the arbitrary gas volume. Consider, e.g., an isothermal gas layer at temperature $T_g$ confined by two infinite parallel plates separated by distance $L$. Direct integration of Eq. (5-116*a*) and use of conservation yield a closed-form expression for the requisite surface-gas direct exchange area

$$\frac{\partial(\overline{s_1 g})}{\partial A_1} = [1 - 2E_3(KL)] \tag{5-139a}$$

where $E_n(z) = \int_{t=1}^{\infty} \frac{e^{-z\cdot t}}{t^n} dt$ is defined as the *nth-order exponential integral* which is readily available. Employing the definition of gas emissivity, the *mean beam length* between the plates $L_M$ is then defined by the expression

$$\varepsilon_g = [1 - 2\cdot E_3(KL)] \equiv 1 - e^{-KL_M} \tag{5-139b}$$

Solution of Eq. (5-139*b*) yields $KL_M = -\ln[2E_3(KL)]$, and it is apparent that $KL_M$ is a function of $KL$. Since $E_n(0) = 1/(n-1)$ for $n > 1$, the mean beam length approximation also correctly predicts the gas emissivity as zero when $K = 0$ and $K \to \infty$.

In the limit $K \to 0$, power series expansion of both sides of Eq. (5-139*b*) leads to $KL_M \to 2KL \equiv KL_{M0}$, where $L_M \equiv L_{M0} = 2L$. Here $L_{M0}$ is defined as the *optically thin mean beam length* for radiant transfer from the entire *infinite* planar gas layer to a differential element of surface area on one of the plates. The optically thin mean beam length for two infinite parallel plates is thus simply *twice* the plate spacing $L$. In a similar manner it may be shown that for a sphere of diameter $D$, $L_{M0} = \frac{2}{3}D$, and for an infinitely long cylinder $L_{M0} = D$. A useful default formula for an arbitrary enclosure of volume $V$ and area $A$ is given by $L_{M0} = 4V/A$. This expression predicts $L_{M0} = \frac{8}{9}R$ for the standard hemisphere of radius $R$ because the optically thin mean beam length is averaged over the *entire* hemispherical enclosure.

Use of the optically thin value of the mean beam length yields values of gas emissivities or exchange areas that are too high. It is thus necessary to introduce a dimensionless constant $\beta \le 1$ and define some new *average mean beam length* such that $KL_M \equiv \beta \cdot KL_{M0}$. For the case of parallel plates, we now require that the mean beam length exactly predict the gas emissivity for a *third* value of $KL$. In this example we find $\beta = -\ln[2E_3(KL)]/2KL$ and for $KL = 0.193095$ there results $\beta = 0.880$. The value $\beta = 0.880$ is not wholly arbitrary. It also happens to minimize the error defined by the so-called shape correction factor $\phi = [\partial(\overline{s_i g})/\partial A_1]/(1 - e^{-KL_M})$ for all $KL > 0$. The required *average* mean beam length for all $KL > 0$ is then taken simply as $L_M = 0.88L_{M0} = 1.76L$. The error in this approximation is less than 5 percent.

For an arbitrary geometry, the *average mean beam length* is defined as the radius of a hemisphere of gas which predicts values of the direct exchange area $s_1 g/A_1 = [1 - \exp(-KL_M)]$, subject to the optimization condition indicated above. It has been found that the error introduced by using average mean beam lengths to approximate direct exchange areas is sufficiently small to be appropriate for many engineering calculations. When it is evaluated for a large number of geometries, it is found that $0.8 < \beta < 0.95$. It is recommended here that $\beta = 0.88$ be employed in lieu of any further geometric information. For a single-gas zone, all the requisite direct exchange areas can be approximated for engineering purposes in terms of a *single* appropriately defined average mean beam length.

**Emissivities of Combustion Products** Absorption or emission of radiation by the constituents of gaseous combustion products is determined primarily by vibrational and rotational transitions between the energy levels of the gaseous molecules. Changes in both vibrational and rotational energy states give rise to *discrete* spectral lines. Rotational lines accompanying vibrational transitions usually overlap, forming a so-called vibration-rotation band. These bands are thus associated with the major vibrational frequencies of the molecules. Each spectral line is characterized by an absorption coefficient $k_{p,\lambda}$ which exhibits a maximum at some central characteristic wavelength or wave number $\eta_0 = 1/\lambda_0$ and is described by a Lorentz* probability distribution. Since the widths of spectral lines are dependent on collisions with other molecules, the absorption coefficient will also depend upon the composition of the combustion gases and the total system pressure. This brief discussion of gas spectroscopy is intended as an introduction to the factors controlling absorption coefficients and thus the factors which govern the empirical correlations to be presented for gas emissivities and absorptivities.

Figure 5-19 shows computed values of the spectral emissivity $\varepsilon_{g\lambda} \equiv \varepsilon_{g\lambda}(T, pL, \lambda)$ as a function of wavelength for an equimolar mixture of carbon dioxide and water vapor for a gas temperature of 1500 K, partial pressure of 0.18 atm, and a path length $L = 2$ m. Three principal absorption-emission bands for $CO_2$ are seen to be centered on 2.7, 4.3, and 15 μm. Two weaker bands at 2 and 9.7 μm are also evident. Three principal absorption-emission bands for water vapor are also identified near 2.7, 6.6, and 20 μm with lesser bands at 1.17, 1.36, and 1.87 μm. The *total* emissivity $\varepsilon_g$ and total absorptivity $\alpha_{g,1}$ are calculated by integration with respect to the wavelength of the spectral emissivities, using Eqs. (5-138) in a manner similar to the development of total surface properties.

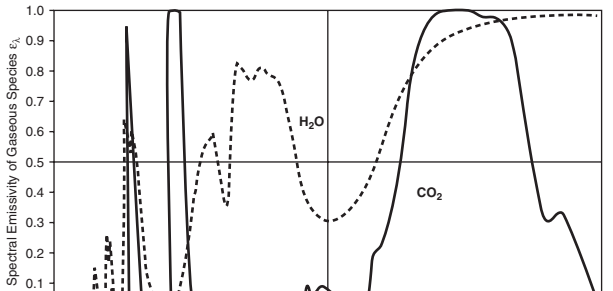

**FIG. 5-19** Spectral emittances for carbon dioxide and water vapor after RADCAL. $p_c L = p_w L = 0.36$ atm · m, $T_g = 1500$ K.

*Spectral lines are conventionally described in terms of wave number $\eta = 1/\lambda$, with each line having a peak absorption at wave number $\eta_0$. The *Lorentz distribution* is defined as $k_\eta/S = \frac{b_c}{\pi[b_c^2 + (\eta - \eta_0)^2]}$ where $S$ is the integral of $k_\eta$ over all wave numbers. The parameter $S$ is known as the integrated line intensity, and $b_c$ is defined as the collision line half-width, i.e., the half-width of the line is one-half of its peak centerline value. The units of $k_\eta$ are $\text{m}^{-1}\,\text{atm}^{-1}$.

***Spectral Emissivities*** Highly resolved spectral emissivities can be generated at ambient temperatures from the HITRAN database (*hi*gh-resolution *tran*smission molecular absorption) that has been developed for atmospheric models [Rothman, L. S., K. Chance, and A. Goldman, eds., *J. Quant. Spectroscopy & Radiative Trans.* **82**(1–4): 2003]. This database includes the chemical species $H_2O$, $CO_2$, $O_3$, $N_2O$, CO, $CH_4$, $O_2$, NO, $SO_2$, $NO_2$, $NH_3$, $HNO_3$, OH, HF, HCl, HBr, ClO, OCS, $H_2CO$, HOCl, $N_2$, HCN, $CH_3C$, HCl, $H_2O_2$, $C_2H_2$, $C_2H_6$, $PH_3$, $COF_2$, $SF_6$, $H_2S$, and $HCO_2H$. These data have been extended to high temperature for $CO_2$ and $H_2O$, allowing for the changes in the population of different energy levels and in the line half width [Denison, M. K., and B. W. Webb, *Heat Transfer*, **2:** 19–24 (1994)]. The resolution in the single-line models of emissivities is far greater than that needed in engineering calculations. A number of models are available that average the emissivities over narrow-wavelength regimes or over the entire band. An extensive set of measurements of narrowband parameters performed at NASA (Ludwig, C., et al., *Handbook of Infrared Radiation from Combustion Gases*, NASA SP-3080, 1973) has been used to develop the RADCAL computer code to obtain spectral emissivities for $CO_2$, $H_2O$, $CH_4$, CO, and soot (Grosshandler, W. L., "RADCAL," NIST Technical Note 1402, 1993). The exponential wideband model is available for emissions averaged over a band for $H_2O$, $CO_2$, CO, $CH_4$, NO, $SO_2$, $N_2O$, $NH_3$, and $C_2H_2$ [Edwards, D. K., and Menard, W. A., *Appl. Optics*, **3:** 621–625 (1964)]. The line and band models have the advantages of being able to account for complexities in determining emissivities of line broadening due to changes in composition and pressure, exchange with spectrally selective walls, and greater accuracy in formulating fluxes in gases with temperature gradients. These models can be used to generate the total emissivities and absorptivities that will be used in this section. RADCAL is a command-line FORTRAN code which is available in the public domain on the Internet.

***Total Emissivities and Absorptivities*** Total emissivities and absorptivities for water vapor and carbon dioxide at present are still based on data embodied in the classical *Hottel emissivity charts.* These data have been adjusted with the more recent measurements in RADCAL and used to develop the correlations of emissivities given in Table 5-6. Two empirical correlations which permit hand calculation of emissivities for water vapor, carbon dioxide, and *four* mixtures of the two gases are presented in Table 5-6. The first section of Table 5-6 provides data for the two constants $b$ and $n$ in the empirical relation

$$\overline{\varepsilon_g T_g} = b[\,pL - 0.015]^n \tag{5-140a}$$

while the second section of Table 5-6 utilizes the *four* constants in the empirical correlation

$$\log(\overline{\varepsilon_g T_g}) = a_0 + a_1 \log(pL) + a_2 \log^2(pL) + a_3 \log^3(pL) \tag{5-140b}$$

In both cases the empirical constants are given for the three temperatures of 1000, 1500, and 2000 K. Table 5-6 also includes six values for the partial pressure ratios $p_W/p_C$ of water vapor to carbon dioxide, namely, 0, 0.5, 1.0, 2.0, 3.0, and ∞. These ratios correspond to composition values of $p_C/(p_C + p_W) = 1/(1 + p_W/p_C)$ of 0, 1/3, 1/2, 2/3, 3/4, and unity. For emissivity calculations at other temperatures and mixture compositions, linear interpolation of the constants is recommended.

NOTE: $p_w/(p_w + p_c)$ of ⅓, ½, ⅔, and ¾ may be used to cover the ranges 0.2–0.4, 0.4–0.6, 0.6–0.7, and 0.7–0.8, respectively, with a maximum error in $\varepsilon_g$ of 5 percent at $pL$ = 6.5 m · atm, less at lower $pL$'s. Linear interpolation reduces the error generally to less than 1 percent. Linear interpolation or extrapolation on $T$ introduces an error generally below 2 percent, less than the accuracy of the original data.

The absorptivity can be obtained from the emissivity with aid of Table 5-6 by using the following functional equivalence.

$$\overline{\alpha_{g,1}T_1} = \left[\overline{\varepsilon_g T}_1\left(pL\cdot T_1/T_g\right)\right]\left(\frac{T_g}{T_1}\right)^{0.5} \tag{5-141}$$

Verbally, the absorptivity computed from Eq. (5-141) by using the correlations in Table 5-6 is based on a value for gas emissivity $\varepsilon_g$ calculated at a temperature $T_1$ and at a partial-pressure path length product of $(p_C + p_W)LT_1/T_g$. The absorptivity is then equal to this value of gas emissivity multiplied by $(T_g/T_1)^{0.5}$. It is recommended that spectrally based models such as RADCAL be used particularly when extrapolating beyond the temperature, pressure, or partial-pressure-length product ranges presented in Table 5-6.

A comparison of the results of the predictions of Table 5-6 with values obtained via the integration of the spectral results calculated from the narrowband model in RADCAL is provided in Fig. 5-20. Here calculations are shown for $p_CL = p_WL = 0.12$ atm·m and a gas temperature of 1500 K. The RADCAL predictions are 20 percent higher than the measurements at low values of *pL* and are 5 percent higher at the large values of *pL*. An extensive comparison of different sources of emissivity data shows that disparities up to 20 percent are to be expected at the current time [Lallemant, N., Sayre, A., and Weber, R., *Prog. Energy Combust. Sci.* **22:** 543–574 (1996)]. However, smaller errors result for the range of the total emissivity measurements presented in the Hottel emissivity tables. This is demonstrated in Example 5-12.

***Example 5-12 Calculations of Gas Emissivity and Absorptivity*** Consider a slab of gas confined between two infinite parallel plates with a distance of separation of $L = 1$ m. The gas pressure is 101.325 kPa (1 atm), and the gas temperature is 1500 K (2240°F). The gas is an equimolar mixture of $CO_2$ and $H_2O$, each with a partial pressure of 12 kPa ($p_C = p_W = 0.12$ atm). The radiative flux to one of its bounding surfaces has been calculated by using RADCAL for two cases. For case (*a*) the flux to the bounding surface is 68.3 kW/m$^2$ when the emitting gas is backed by a black surface at an ambient temperature of 300 K (80°F). This (cold) back surface contributes less than 1 percent to the flux. In case (*b*), the flux is calculated as 106.2 kW/m$^2$ when the gas is backed by a black surface at a temperature of 1000 K (1340°F). In this example, gas emissivity and absorptivity are to be computed from these flux values and compared with values obtained by using Table 5-6.

*Case (a):* The flux incident on the surface is equal to $\varepsilon_g\cdot\sigma\cdot T_g^4 = 68.3$ kW/m$^2$; therefore, $\varepsilon_g = 68{,}300/(5.6704\times10^{-8}\cdot1500^4) = 0.238$. To utilize Table 5-6, the mean beam length for the gas is calculated from the relation $L_M = 0.88L_{M0} = 0.88\cdot2L = 1.76$ m. For $T_g = 1500$ K and $(p_C + p_W)L_M = 0.24(1.76) = 0.422$ atm·m, the two-constant correlation in Table 5-6 yields $\varepsilon_g = 0.230$ and the four-constant correlation yields $\varepsilon_g = 0.234$. These results are clearly in excellent agreement with the predicted value of $\varepsilon_g = 0.238$ obtained from RADCAL.

*Case (b):* The flux incident on the surface (106.2 kW/m$^2$) is the sum of that contributed by (1) gas emission $\varepsilon_g\cdot\sigma\cdot T_g^4 = 68.3$ kW/m$^2$ and (2) emission from the opposing surface corrected for absorption by the intervening gas using the gas transmissivity, that is, $\tau_{g,1}\sigma\cdot T_1^4$ where $\tau_{g,1} = 1 - \alpha_{g,1}$. Therefore $\alpha_{g,1} = [1 - (106{,}200 - 68{,}300)/(5.6704\times10^{-8}\cdot1000^4)] = 0.332$. Using Table 5-6, the two-constant and four-constant gas emissivities evaluated at $T_1 = 1000$ K and $pL = 0.4224\times(1000/1500) = 0.282$ atm·m are $\varepsilon_g = 0.2654$ and $\varepsilon_g = 0.2707$, respectively. Multiplication by the factor $(T_g/T_1)^{0.5} = (1500/1000)^{0.5} = 1.225$ produces the final values of the two corresponding gas absorptivities $\alpha_{g,1} = 0.325$ and $\alpha_{g,1} = 0.332$, respectively. Again the agreement with RADCAL is excellent.

***Other Gases*** The most extensive available data for gas emissivity are those for carbon dioxide and water vapor because of their importance in the radiation from the products of fossil fuel combustion. Selected data for other species present in combustion gases are provided in Table 5-7.

**Flames and Particle Clouds**

***Luminous Flames*** Luminosity conventionally refers to soot radiation. At atmospheric pressure, soot is formed in locally fuel-rich portions of flames in amounts that usually correspond to less than 1 percent of the carbon in the fuel. Because soot particles are small relative to the wavelength of the radiation of interest in flames (primary particle diameters of soot are of the order of 20 nm compared to wavelengths of interest of 500 to 8000 nm), the incident radiation permeates the particles, and the absorption is proportional to the volume of the particles. In the limit of $r_p/\lambda << 1$, the Rayleigh limit, the monochromatic emissivity $\varepsilon_\lambda$ is given by

$$\varepsilon_\lambda = 1 - \exp(-K\cdot f_v\cdot L/\lambda) \tag{5-142}$$

where $f_v$ is the volumetric soot concentration, $L$ is the path length in the same units as the wavelength $\lambda$, and $K$ is dimensionless. The value $K$ will vary with fuel type, experimental conditions, and temperature history of the soot. The values of $K$ for a wide range of systems are within a factor of about 2 of one another. The single most important variable governing the value of $K$ is the hydrogen/carbon ratio of the soot, and the value of $K$ increases as the H/C ratio decreases. A value of $K = 9.9$ is recommended on the basis of seven studies involving 29 fuels [Mulholland, G. W., and Croarkin, C., *Fire and Materials*, **24:** 227–230 (2000)].

The total emissivity of soot $\varepsilon_S$ can be obtained by substituting $\varepsilon_\lambda$ from Eq. (5-142) for $\varepsilon_\lambda$ in Eq. (5-138*a*) to yield

$$\varepsilon_S = \int_{\lambda=0}^{\infty}\varepsilon_\lambda\frac{E_{b,\lambda}(T_g,\lambda)}{E_b(T_g)}d\lambda = 1 - \frac{15}{4}[\Psi^{(3)}(1+K\cdot f_v\cdot L\cdot T/c_2)] \cong (1+K\cdot f_v\cdot L\cdot T/c_2)^{-4} \tag{5-143}$$

Here $\Psi^{(3)}(x)$ is defined as the pentagamma function of $x$, and $c_2$ (m·K) is again Planck's second constant. The approximate relation in Eq. (5-143) is

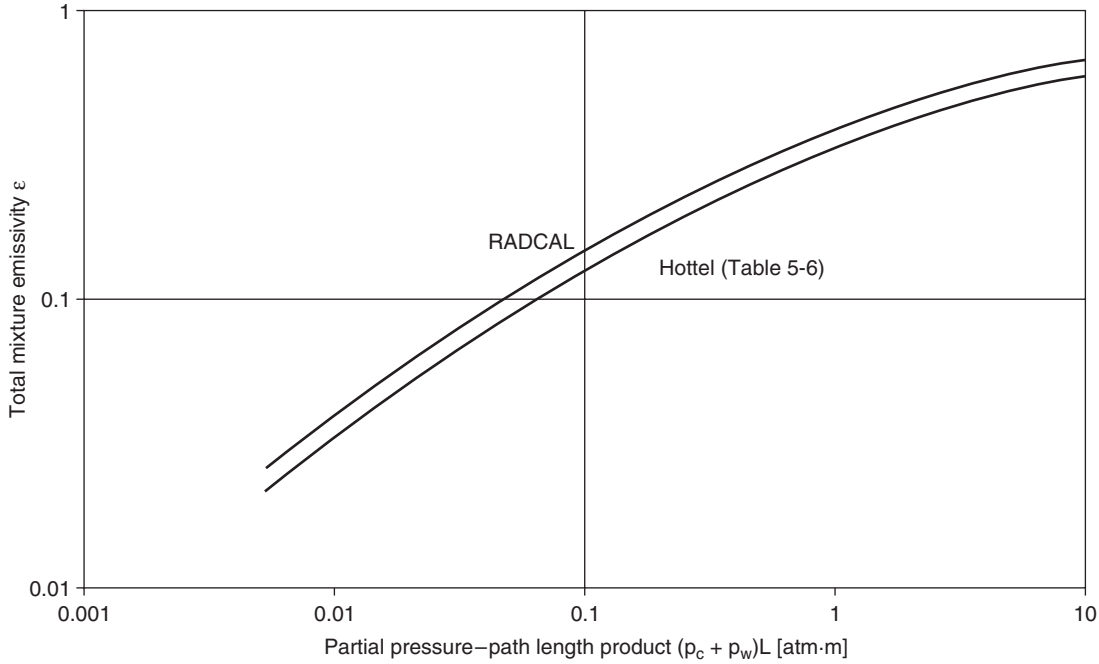

**FIG. 5-20** Comparison of Hottel and RADCAL total gas emissivities. Equimolal gas mixture of $CO_2$ and $H_2O$ with $p_c = p_w = 0.12$ atm and $T_g = 1500$ K.

accurate to better than 1 percent for arguments yielding values of $\varepsilon_S < 0.7$. At present, the largest uncertainty in estimating total soot emissivities lies in the estimation of the soot volume fraction $f_v$. Soot forms in the fuel-rich zones of flames. Soot formation rates are a function of fuel type, mixing rate, local equivalence ratio $\Phi$, temperature, and pressure. The *equivalence ratio* is defined as the quotient of the actual to stoichiometric fuel-to-oxidant ratio $\Phi = [F/O]_{act}/[F/O]_{stoich}$. Soot formation increases with the aromaticity or C/H ratio of fuels with benzene, α-methyl naphthalene, and acetylene having a high propensity to form soot and methane having a low soot formation propensity. Oxygenated fuels, such as alcohols, emit little soot. In practical turbulent diffusion flames, soot forms on the fuel side of the flame front. In premixed flames, at a given temperature, the rate of soot formation increases rapidly for $\Phi > 2$. For temperatures above 1500 K, soot burns out rapidly (in less than 0.1 s) under fuel-lean conditions, $\Phi < 1$. Because of this rapid soot burnout, soot is usually localized in a relatively small fraction of a furnace or combustor volume. Long, poorly mixed diffusion flames promote soot formation while highly back-mixed combustors can burn soot-free. In a typical flame at atmospheric pressure, maximum volumetric soot concentrations are found to be in the range of $10^{-7} < f_v < 10^{-6}$. This corresponds to a soot formation of about 1.5 to 15 percent of the carbon in the fuel. When $f_v$ is to be calculated at high pressures, allowance must be made for the significant increase in soot formation with pressure and for the inverse proportionality of $f_v$ with respect to pressure. Great progress is being made in the ability to calculate soot in premixed flames. For example, predicted and measured soot concentration has been compared in a well-stirred reactor operated over a wide range of temperatures and equivalence ratios [Brown, N. J., Revzan, K. L., and Frenklach, M., *Twenty-seventh Symposium (International) on Combustion*, pp. 1573–1580, 1998]. Moreover, computational fluid dynamics (CFD) and population dynamics modeling have been used to simulate soot formation in a turbulent non-premixed ethylene-air flame [Zucca et al., *Chem. Eng. Sci.* **61:** 87–95 (2006)]. The importance of soot radiation varies widely between combustors. In large boilers the soot is confined to small volumes and is of only local importance. In gas turbines, cooling the combustor liner is of primary importance so that only small incremental soot radiation is of concern. In high-temperature glass tanks, the presence of soot adds 0.1 to 0.2 to emissivities of oil-fired flames. In natural gas-fired flames, efforts to augment flame emissivities with soot generation generally have been unsuccessful. The contributions of soot to the radiation from pool fires often dominates, and thus the presence of soot in such flames directly impacts the safe separation distances from dikes around oil tanks and the location of flares with respect to oil rigs.

***Clouds of Large Black Particles*** The emissivity $\varepsilon_M$ of a cloud of black particles with a large perimeter-to-wavelength ratio is

$$\varepsilon_M = 1 - \exp[-(a/\upsilon)L] \tag{5-144}$$

where $a/\upsilon$ is the projected area of the particles per unit volume of space. If the particles have no negative curvature (the particle does not "see" any of itself) and are randomly oriented, $a = a'/4$, where $a'$ is the actual surface area. If the particles are uniform, $a/\upsilon = cA = cA'/4$, where $A$ and $A'$ are the projected and total areas of each particle, respectively, and $c$ is the number concentration of particles. For spherical particles this leads to

$$\varepsilon_M = 1 - \exp[-(\pi/4)cd_p^2L] = 1 - \exp(-1.5 f_v L/d_p) \tag{5-145}$$

As an example, consider a heavy fuel oil ($CH_{1.5}$, specific gravity of 0.95) atomized to a mean surface particle diameter of $d_p$ burned with 20 percent excess air to produce coke-residue particles having the original drop diameter and suspended in combustion products at 1204°C (2200°F). The flame emissivity due to the particles along a path of $L$ m, with $d_p$ measured in micrometers, is

$$\varepsilon_M = 1 - \exp(-24.3L/d_p) \tag{5-146}$$

For 200-μm particles and $L = 3.05$ m, the particle contribution to emissivity is calculated as 0.31.

***Clouds of Nonblack Particles*** For nonblack particles, emissivity calculations are complicated by multiple scatter of the radiation reflected by each particle. The emissivity $\varepsilon_M$ of a cloud of gray particles of individual emissivity $\varepsilon_1$ can be estimated by the use of a simple modification Eq. (5-144), i.e.,

$$\varepsilon_M = 1 - \exp[-\varepsilon_1(a/\upsilon)L] \tag{5-147}$$

Equation (5-147) predicts that $\varepsilon_M \to 1$ as $L \to \infty$. This is *impossible* in a scattering system, and use of Eq. (5-147) is restricted to values of the optical thickness $(a/\upsilon)L < 2$. Instead, the asymptotic value of $\varepsilon_M$ is obtained from Fig. 5-12 as $\varepsilon_M = \varepsilon_h\,(\lim L \to \infty)$, where the albedo $w$ is replaced by the particle-surface reflectance $\omega = 1 - \varepsilon_1$. Particles with perimeter-to-wavelength ratios of 0.5 to 5.0 can be analyzed, with significant mathematical complexity, by use of the the *Mie equations* (Bohren, C. F., and Huffman, D. R., *Absorption and Scattering of Light by Small Particles*, Wiley, Hoboken, N.J., 1998).

***Combined Gas, Soot, and Particulate Emission*** In a mixture of emitting species, the emission of each constituent is attenuated on its way to the system boundary by absorption by all other constituents. The transmissivity of a mixture is the product of the transmissivities of its component parts. This statement is a corollary of Beer's law. For present purposes, the transmissivity of "species $k$" is defined as $\tau_k = 1 - \varepsilon_k$. For a mixture of combustion products consisting of carbon dioxide, water vapor, soot, and oil coke or char particles, the total emissivity $\varepsilon_T$ at any wavelength can therefore be obtained from

$$(1-\varepsilon_T)_\lambda = (1-\varepsilon_C)_\lambda (1-\varepsilon_W)_\lambda (1-\varepsilon_S)_\lambda (1-\varepsilon_M)_\lambda \tag{5-148}$$

where the subscripts denote the four flame species. The total emissivity is then obtained by integrating Eq. (5-148) over the entire EM energy spectrum, taking into account the variability of $\varepsilon_C$, $\varepsilon_W$, and $\varepsilon_S$ with respect to wavelength. In Eq. (5-148), $\varepsilon_M$ is independent of wavelength because absorbing char or coke particles are effectively blackbody absorbers. Computer programs for spectral emissivity, such as RADCAL, perform the integration with respect to wavelength for obtaining total emissivity. Corrections for the overlap of vibration-rotation bands of $CO_2$ and $H_2O$ are automatically included in the correlations for $\varepsilon_g$ for mixtures of these gases. The monochromatic soot emissivity is higher at shorter wavelengths, resulting in higher attenuations of the bands at 2.7 μm for $CO_2$ and $H_2O$ than at longer wavelengths. The following equation is recommended for calculating the emissivity $\varepsilon_{g+S}$ of a mixture of $CO_2$, $H_2O$, and soot

$$\varepsilon_{g+S} = \varepsilon_g + \varepsilon_S - M \cdot \varepsilon_g \varepsilon_S \tag{5-149}$$

where $M$ can be represented with acceptable error by the dimensionless function

$$M = 1.12 - 0.27 \cdot (T/1000) + 2.7 \times 10^5 f_v \cdot L \tag{5-150}$$

In Eq. (5-150), $T$ has units of kelvins and $L$ is measured in meters. Since coke or char emissivities are gray, their addition to those of the $CO_2$, $H_2O$, and soot follows simply from Eq. (5-148) as

$$\varepsilon_T = \varepsilon_{g+S} + \varepsilon_M - \varepsilon_{g+S}\varepsilon_M \tag{5-151}$$

with the definition $1-\varepsilon_{g+S} \equiv (1-\varepsilon_C)(1-\varepsilon_W)(1-\varepsilon_S)$.

## RADIATIVE EXCHANGE WITH PARTICIPATING MEDIA

**Energy Balances for Volume Zones—The Radiation Source Term** Reconsider a generalized enclosure with $N$ volume zones confining a *gray* gas. When the $N$ gas temperatures are *unknown*, an *additional* set of $N$ equations is required in the form of radiant energy balances for each volume zone. These $N$ equations are given by the *definition* of the $N$-vector for the *net radiant volume absorption* $\mathbf{S}' = [S_i']$ for each volume zone

$$\mathbf{S}' = \overline{\mathbf{GS}} \cdot \mathbf{E} + \overline{\mathbf{GG}} \cdot \mathbf{E}_g - 4K \cdot \mathbf{VI} \cdot \mathbf{E}_g \qquad [N \times 1] \tag{5-152}$$

The radiative source term is a discretized formulation of the *net radiant absorption* for each volume zone which may be incorporated as a *source term* into numerical approximations for the generalized *energy equation*. As such, it permits formulation of energy balances on each zone that may include conductive and convective heat transfer. For $K \to 0$, $\overline{\mathbf{GS}} \to 0$, and $\overline{\mathbf{GG}} \to 0$ leading to $\mathbf{S}' \to \mathbf{0}_N$. When $K \neq 0$ and $\mathbf{S}' = \mathbf{0}_N$, the gas is said to be in a state of *radiative equilibrium*. In the notation usually associated with the discrete ordinate (DO) and finite volume (FV) methods, see Modest (*Radiative Heat Transfer,* 3d ed., Academic Press, New York, 2013, chap. 17), one would write $S_i'/V_i = K[G - 4 \cdot E_g] = -\nabla \cdot \bar{\mathbf{q}}_\mathbf{r}$. Here $H_g = G/4$ is the average flux density incident on a given volume zone from all other surface and volume zones. The DO and FV methods are currently available options as "RTE-solvers" in complex simulations of combustion systems using computational fluid dynamics (CFD).*

Implementation of Eq. (5-152) necessitates the definition of two additional *symmetric* $N \times N$ arrays of exchange areas, namely, $\overline{\mathbf{gg}} = [\overline{g_i g_j}]$ and $\overline{\mathbf{GG}} = [\overline{G_i G_j}]$. In Eq. (5-152) $\mathbf{VI} = [V_i \cdot \delta_{i,j}]$ is an $N \times N$ diagonal matrix of zone volumes. The total exchange areas in Eq. (5-151) are *explicit* functions of the direct exchange areas as follows:

Surface-to-gas exchange

$$\overline{\mathbf{GS}} = \overline{\mathbf{SG}}^T \qquad [N \times M] \tag{5-153a}$$

Gas-to-gas exchange

$$\overline{\mathbf{GG}} = \overline{\mathbf{gg}} + \overline{\mathbf{sg}}^T \cdot \rho\mathbf{I} \cdot \mathbf{R} \cdot \overline{\mathbf{sg}} \qquad [N \times M] \tag{5-153b}$$

The matrices $\overline{\mathbf{gg}} = [\overline{g_i g_j}]$ and $\overline{\mathbf{GG}} = [\overline{G_i G_j}]$ must also satisfy the following *matrix conservation relations:*

Direct exchange areas: $$4K \cdot \mathbf{VI} \cdot \mathbf{1}_N = \overline{\mathbf{gs}} \cdot \mathbf{1}_M + \overline{\mathbf{gg}} \cdot \mathbf{1}_N \tag{5-154a}$$

Total exchange areas: $$4K \cdot \mathbf{VI} \cdot \mathbf{1}_N = \overline{\mathbf{GS}} \cdot \mathbf{1}_M + \overline{\mathbf{GG}} \cdot \mathbf{1}_N \tag{5-154b}$$

The formal integral definition of the direct gas-gas exchange area is

$$\overline{g_i g_j} = \iiint_{V_i} \iiint_{V_j} K^2 \frac{e^{-Kr}}{\pi r^2} \, dV_j \, dV_i \tag{5-155}$$

Clearly, when $K = 0$, the two direct exchange areas involving a gas zone $\overline{g_i s_j}$ and $\overline{s_i g_j}$ vanish. Computationally it is *never* necessary to make resort to Eq. (5-155) for calculation of $\overline{g_i g_j}$. This is so because, $\overline{s_i g_j}$, $\overline{s_i g_j}$, and $\overline{g_i g_j}$ may *all* be calculated *arithmetically* from appropriate values of $\overline{s_i s_j}$ by using associated conservation relations and view factor algebra.

**Weighted Sum of Gray Gas (WSGG) Spectral Model** Even in simple engineering calculations, the assumption of a gray gas is almost never a good one. The zone method is now further generalized to make allowance for nongray radiative transfer via incorporation of the *weighted sum of gray gas* (WSGG) spectral model. Hottel has shown that the emissivity $\varepsilon_g(T, L)$ of an absorbing-emitting gas mixture containing $CO_2$ and $H_2O$ of known composition can be approximated by a *weighted sum of P gray gases*

$$\varepsilon_g(T, L) \approx \sum_{p=1}^{P} a_p(T)[1 - e^{-K_p L}] \tag{5-156a}$$

where

$$\sum_{p=1}^{P} a_p(T) = 1.0 \tag{5-156b}$$

In Eqs. (5-156), $K_p$ is some gray gas absorption coefficient and $L$ is some appropriate path length. In practice, Eqs. (5-156) usually yield acceptable accuracy for $P \leq 3$. For $P = 1$, Eqs. (5-156) degenerate to the case of a single gray gas.

***The Clear Plus Gray Gas WSGG Spectral Model*** In principle, the emissivity of all gases approaches unity for infinite path length $L$. In practice, however, the gas emissivity may fall considerably short of unity for representative values of $pL$. This behavior results because of the *band* nature of real gas spectral absorption and emission whereby there is usually no significant overlap between dominant absorption bands. Mathematically, this physical phenomenon is modeled by defining one of the gray gas components in the WSGG spectral model to be *transparent*.

For $P = 2$ and path length $L_M$, Eqs. (5-156) yield the following expression for the gas emissivity

$$\varepsilon_g = a_1(1 - e^{-K_1 L_M}) + a_2(1 - e^{-K_2 L_M}) \tag{5-157}$$

In Eq. (5-157) if $K_1 = 0$ and $a_2 \neq 0$, the limiting value of gas emissivity is $\varepsilon_g(T, \infty) \to a_2$. Put $K_1 = 0$ in Eq. (5-157), $a_g = a_2$, and define $\tau_g = e^{-K_2 L_M}$ as the gray gas transmissivity. Equation (5-157) then simplifies to

$$\varepsilon_g = a_g(1 - \tau_g) \tag{5-158}$$

It is important to note in Eq. (5-158) that $0 \leq a_g, \tau_g \leq 1.0$ while $0 \leq \varepsilon_g \leq a_g$.

Equation (5-158) constitutes a two-parameter model which may be fitted with only *two* empirical emissivity data points. To obtain the constants $a_g$ and $\tau_g$ in Eq. (5-158) at fixed composition and temperature, denote the two emissivity data points as $\varepsilon_{g,2} = \varepsilon_g(2\,pL) > \varepsilon_{g,1} = \varepsilon_g(pL)$ and recognize that $\varepsilon_{g,1} = a_g(1 - \tau_g)$ and $\varepsilon_{g,2} = a_g(1 - \tau_g^2) = a_g(1 - \tau_g)(1 + \tau_g) = \varepsilon_{g,1}(1 + \tau_g)$. These relations lead directly to the final emissivity fitting equations

$$\tau_g = \frac{\varepsilon_{g,2}}{\varepsilon_{g,1}} - 1 \tag{5-159a}$$

and

$$a_g = \frac{\varepsilon_{g,1}}{2 - \varepsilon_{g,2}/\varepsilon_{g,1}} \tag{5-159b}$$

The clear plus gray WSGG spectral model also readily leads to values for gas *absorptivity* and *transmissivity*, with respect to some appropriate surface radiation source at temperature $T_1$, for example,

$$\alpha_{g,1} = a_{g,1}(1 - \tau_g) \tag{5-160a}$$

and

$$\tau_{g,1} = a_{g,1} \cdot \tau_g \tag{5-160b}$$

In Eqs. (5-160) the *gray* gas transmissivity $\tau_g$ is taken to be identical to that obtained for the gas emissivity $\varepsilon_g$. The constant $a_{g,1}$ in Eq. (5-160*a*) is then obtained with knowledge of *one additional empirical value* for $\alpha_{g,1}$ which may also be obtained from the correlations in Table 5-6. Notice further in the definitions of the three parameters $\varepsilon_g$, $\alpha_{g,1}$, and $\tau_{g,1}$ that *all* the temperature dependence is forced into the *two* WSGG constants $a_g$ and $a_{g,1}$.

The *three* clear plus gray WSGG constants $a_g$, $a_{g,1}$, and $\tau_g$ are functions of total pressure, temperature, and mixture composition. It is not necessary to ascribe any particular physical significance to them. Rather, they may simply be visualized as three constants that happen to fit the gas emissivity data. It is noteworthy that *three* constants are far fewer than the number required to calculate gas emissivity data from fundamental spectroscopic data.

*To further clarify the mathematical differences between zoning and the DO and FV methods, recognize that (neglecting scatter) the matrix expressions $\mathbf{H} = \mathbf{AI}^{-1} \cdot \overline{\mathbf{ss}} \cdot \mathbf{W} + \mathbf{AI}^{-1} \cdot \overline{\mathbf{sg}} \cdot \mathbf{E}_g$ and $4K \cdot \mathbf{H}_g = \mathbf{VI}^{-1} \cdot \overline{\mathbf{gs}} \cdot \mathbf{W} + \mathbf{VI}^{-1} \cdot \overline{\mathbf{gg}} \cdot \mathbf{E}_g$ represent spatial discretizations of the integral form(s) of the RTE applied at any point (zone) on the boundary or interior of an enclosure, respectively, for a gray gas.

The two constants $a_g$ and $a_{g,1}$ defined in Eqs. (5-158) and (5-160) can, however, be interpreted *physically* in a particularly simple manner. Suppose the gas absorption spectrum is idealized by *many* absorption bands (boxes), *all* of which are characterized by the *identical* absorption coefficient $K$. The $a$'s might then be calculated from the total blackbody energy fraction $F_b(\lambda T)$ defined in Eqs. (5-105) and (5-106). That is, $a_g$ simply represents the total *energy fraction* of the blackbody energy distribution in which the gas *absorbs*. This concept may be further generalized to real gas absorption spectra via the *wideband stepwise gray spectral box model* (Modest, *Radiative Heat Transfer,* 3d ed., Academic Press, New York, 2013, chap. 14).

When $P \geq 3$, exponential curve-fitting procedures for the WSGG spectral model become significantly more difficult for hand computation but are quite routine with the aid of a variety of readily available mathematical software utilities. The clear plus gray WSGG fitting procedure is demonstrated in Example 5-13.

**The Zone Method and Directed Exchange Areas** Spectral dependence of real gas spectral properties is now introduced into the zone method via the WSGG spectral model. It is still assumed, however, that all surface zones are gray isotropic emitters and absorbers.

***General Matrix Representation*** We first define a new set of four *directed exchange areas* $\overrightarrow{\mathbf{SS}}, \overrightarrow{\mathbf{SG}}, \overleftarrow{\mathbf{GS}}$, and $\overleftarrow{\mathbf{GG}}$, which are denoted by an overarrow. The directed exchange areas are obtained from the total exchange areas for gray gases by simple matrix multiplication using weighting factors derived from the WSGG spectral model. The directed exchange areas are denoted by an overarrow to indicate the "sending" and "receiving" zone. The $a$-weighting factors for transfer originating at a gas zone $a_{g,i}$ are derived from WSGG gas *emissivity* calculations, while those for transfers originating at a surface zone $a_i$ are derived from appropriate WSGG gas *absorptivity* calculations. Let $\mathbf{a}_g\mathbf{I}_p = [a_{p,g,i} \cdot \delta_{i,j}]$ and $\mathbf{aI}_p = [a_{p,i} \cdot \delta_{i,j}]$ represent the $P$ $[M \times M]$ and $[N \times N]$ *diagonal* matrices comprised of the appropriate WSGG $a$ constants. The *directed* exchange areas are then computed from the associated *total* gray gas exchange areas via simple *diagonal* matrix multiplication.

$$\overrightarrow{\mathbf{SS}} = \sum_{p=1}^{P} \overrightarrow{\mathbf{SS}}_p \cdot \mathbf{aI}_p \qquad [M \times M] \tag{5-161a}$$

$$\overrightarrow{\mathbf{SG}} = \sum_{p=1}^{P} \overrightarrow{\mathbf{SG}}_p \cdot \mathbf{a}_g\mathbf{I}_p \qquad [M \times N] \tag{5-161b}$$

$$\overleftarrow{\mathbf{GS}} = \sum_{p=1}^{P} \overleftarrow{\mathbf{GS}}_p \cdot \mathbf{aI}_p \qquad [M \times N] \tag{5-161c}$$

$$\overleftarrow{\mathbf{GG}} = \sum_{p=1}^{P} \overleftarrow{\mathbf{GG}}_p \cdot \mathbf{a}_g\mathbf{I}_p \qquad [N \times N] \tag{5-161d}$$

with

$$\overleftarrow{\mathbf{KI}} = \sum_{p=1}^{P} \mathbf{KI}_p \cdot \mathbf{a}_g\mathbf{I}_p \qquad [N \times N] \tag{5-161e}$$

In contrast to the *total* exchange areas which are always independent of temperature, the four *directed* arrays $\overrightarrow{\mathbf{SS}}, \overrightarrow{\mathbf{SG}}, \overleftarrow{\mathbf{GS}}$, and $\overleftarrow{\mathbf{GG}}$ are dependent on the temperatures of each and every zone, i.e., as in $a_{p,i} = a_p(T_i)$. Moreover, in contrast to *total* exchange areas, the *directed* arrays $\overrightarrow{\mathbf{SS}}$ and $\overleftarrow{\mathbf{GG}}$ are generally not symmetric and $\overrightarrow{\mathbf{GS}} \neq \overrightarrow{\mathbf{SG}}^{\mathrm{T}}$. Finally, since the directed exchange areas are temperature-*dependent*, iteration may be required to update the $\mathbf{aI}_p$ and $\mathbf{a}_g\mathbf{I}_p$ arrays during the course of a calculation. There is a great deal of latitude with regard to fitting the WSGG $a$ constants in these matrix equations, especially if $N > 1$ and composition variations are to be allowed for in the gas. An extensive discussion of $a$ fitting for $N > 1$ is beyond the scope of this presentation. Details of the fitting procedure, however, are presented in Example 5-13 in the context of a single-gas zone.

Once the directed exchange areas are formulated, the governing matrix equations for the radiative flux equations at each surface zone and the radiant source term are then given as follows:

$$\mathbf{Q} = \boldsymbol{\varepsilon}\mathbf{AI} \cdot \mathbf{E} - \overrightarrow{\mathbf{SS}} \cdot \mathbf{E} - \overrightarrow{\mathbf{SG}} \cdot \mathbf{E}_g \tag{5-162a}$$

$$\mathbf{S}' = \overleftarrow{\mathbf{GG}} \cdot \mathbf{E}_g + \overleftarrow{\mathbf{GS}} \cdot \mathbf{E} - 4 \cdot \overleftarrow{\mathbf{KI}} \cdot \mathbf{VI} \cdot \mathbf{E}_g \tag{5-162b}$$

or the alternative forms

$$\mathbf{Q} = \left[\mathbf{EI} \cdot \overrightarrow{\mathbf{SS}} - \overrightarrow{\mathbf{SS}} \cdot \mathbf{EI}\right] \cdot \mathbf{1}_M + \left[\mathbf{EI} \cdot \overrightarrow{\mathbf{SG}} - \overrightarrow{\mathbf{SG}} \cdot \mathbf{E}_g\mathbf{I}\right] \cdot \mathbf{1}_N \tag{5-163a}$$

$$\mathbf{S}' = -[\mathbf{E}_g\mathbf{I} \cdot \overleftarrow{\mathbf{GS}} - \overleftarrow{\mathbf{GS}} \cdot \mathbf{EI}] \cdot \mathbf{1}_M - [\mathbf{E}_g\mathbf{I} \cdot \overleftarrow{\mathbf{GG}} - \overleftarrow{\mathbf{GG}} \cdot \mathbf{E}_g\mathbf{I}] \cdot \mathbf{1}_N \tag{5-163b}$$

It may be *proved* that the $\mathbf{Q}$ and $\mathbf{S}'$ vectors computed from Eqs. (5-162) and (5-163) always *exactly* satisfy the overall (scalar) *radiant* energy balance $\mathbf{I}_M^T \cdot \mathbf{Q} = \mathbf{I}_N^T \cdot \mathbf{S}'$. In words, the total radiant gas emission for all gas zones in the enclosure must always exactly equal the total radiant energy received at all surface zones which comprise the enclosure. In Eqs. (5-162) and (5-163), the following definitions are employed for the *four forward-directed* exchange areas

$$\overrightarrow{\mathbf{SS}} = \overrightarrow{\mathbf{SS}} \quad \overrightarrow{\mathbf{SG}} = \overrightarrow{\mathbf{GS}}^{\mathrm{T}} \quad \overleftarrow{\mathbf{GS}} = \overrightarrow{\mathbf{SG}}^{\mathrm{T}} \quad \overleftarrow{\mathbf{GG}} = \overleftarrow{\mathbf{GG}}^{\mathrm{T}} \tag{5-164a,b,c,d}$$

such that formally there are some *eight* matrices of directed exchange areas. The four *backward-directed* arrays of directed exchange areas must satisfy the following conservation relations:

$$\overrightarrow{\mathbf{SS}} \cdot \mathbf{1}_M + \overrightarrow{\mathbf{SG}} \cdot \mathbf{1}_N = \boldsymbol{\varepsilon}\mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{1}_M \tag{5-165a}$$

$$4\overleftarrow{\mathbf{KI}} \cdot \mathbf{VI} \cdot \mathbf{1}_N = \overleftarrow{\mathbf{GS}} \cdot \mathbf{1}_M + \overleftarrow{\mathbf{GG}} \cdot \mathbf{1}_N \tag{5-165b}$$

Subject to the restrictions of no scatter and diffuse surface emission and reflection, the above equations are the most general matrix statement possible for the zone method. When $P = 1$, the *directed* exchange areas all reduce to the *total* exchange areas for a single gray gas. If, in addition, $K = 0$, the much simpler case of radiative transfer in a transparent medium results. If, in addition, all surface zones are *black*, the direct, total, and directed exchange areas are all identical.

***Allowance for Flux Zones*** As in the case of a transparent medium, we now distinguish between source and flux surface zones. Let $M = M_s + M_f$ represent the total number of surface zones where $M_s$ is the number of source-sink zones and $M_f$ is the number of flux zones. The flux zones are the *last to be numbered.* To accomplish this, partition the surface emissive power and flux vectors as $\mathbf{E} = \begin{bmatrix} \mathbf{E}_1 \\ \mathbf{E}_2 \end{bmatrix}$ and $\mathbf{Q} = \begin{bmatrix} \mathbf{Q}_1 \\ \mathbf{Q}_2 \end{bmatrix}$, where subscript 1 denotes surface source/sink zones whose emissive power $\mathbf{E}_1$ is specified a priori and subscript 2 denotes surface flux zones of unknown emissive power vector $\mathbf{E}_2$ and known radiative flux vector $\mathbf{Q}_2$. Suppose the radiative source vector $\mathbf{S}'$ is *known.* Appropriate partitioning of Eqs. (5-162) then produces

$$\begin{bmatrix} \mathbf{Q}_1 \\ \mathbf{Q}_2 \end{bmatrix} = \begin{bmatrix} \boldsymbol{\varepsilon}\mathbf{AI}_{1,1} & \mathbf{0} \\ \mathbf{0} & \boldsymbol{\varepsilon}\mathbf{AI}_{2,2} \end{bmatrix} \cdot \begin{bmatrix} \mathbf{E}_1 \\ \mathbf{E}_2 \end{bmatrix} \begin{bmatrix} \overrightarrow{\mathbf{SS}}_{1,1} & \overrightarrow{\mathbf{SS}}_{1,2} \\ \overrightarrow{\mathbf{SS}}_{2,1} & \overrightarrow{\mathbf{SS}}_{2,2} \end{bmatrix} \cdot \begin{bmatrix} \mathbf{E}_1 \\ \mathbf{E}_2 \end{bmatrix} - \begin{bmatrix} \overrightarrow{\mathbf{SG}}_1 \\ \overrightarrow{\mathbf{SG}}_2 \end{bmatrix} \cdot \mathbf{E}_g \tag{5-166a}$$

and

$$\mathbf{S}' = \overleftarrow{\mathbf{GG}} \cdot \mathbf{E}_g + \begin{bmatrix} \overleftarrow{\mathbf{GS}}_1 & \overleftarrow{\mathbf{GS}}_2 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{E}_1 \\ \mathbf{E}_2 \end{bmatrix} - 4 \cdot \overleftarrow{\mathbf{KI}} \cdot \mathbf{VI} \cdot \mathbf{E}_g \tag{5-166b}$$

where the definitions of the matrix partitions follow the conventions with respect to Eq. (5-120). Simultaneous solution of the *two* unknown vectors in Eqs. (5-166) then yields

$$\mathbf{E}_2 = \mathbf{RP} \cdot \left[\overrightarrow{\mathbf{SS}}_{2,1} + \overrightarrow{\mathbf{SG}}_2 \cdot \mathbf{PP} \cdot \overleftarrow{\mathbf{GS}}_1\right] \cdot \mathbf{E}_1 + \mathbf{RP} \cdot \left[\mathbf{Q}_2 - \overrightarrow{\mathbf{SG}}_2 \cdot \mathbf{PP} \cdot \mathbf{S}'\right] \tag{5-167a}$$

and

$$\mathbf{E}_g = \mathbf{PP} \cdot \begin{bmatrix} \overleftarrow{\mathbf{GS}}_1 & \overleftarrow{\mathbf{GS}}_2 \end{bmatrix} \cdot \begin{bmatrix} \mathbf{E}_1 \\ \mathbf{E}_2 \end{bmatrix} - \mathbf{PP} \cdot \mathbf{S}' \tag{167b}$$

where two auxiliary inverse matrices **RP** and **PP** are defined as

$$\mathbf{PP} = \left[4 \cdot \overleftarrow{\mathbf{KI}} \cdot \mathbf{VI} - \overleftarrow{\mathbf{GG}}\right]^{-1} \tag{5-168a}$$

$$\mathbf{RP} = \left[\boldsymbol{\varepsilon}\mathbf{AI}_{2,2} - \overrightarrow{\mathbf{SS}}_{2,2} - \overrightarrow{\mathbf{SG}}_2 \cdot \mathbf{PP} \cdot \overleftarrow{\mathbf{GS}}_2\right]^{-1} \tag{5-168b}$$

The emissive power vectors $\mathbf{E}$ and $\mathbf{E}_g$ are then both *known* quantities for purposes of subsequent calculation.

**Algebraic Formulas for a Single-Gas Zone** As shown in Fig. 5-16, the three-zone system with $M = 2$ and $N = 1$ can be employed to simulate a surprisingly large number of useful engineering geometries. These include two infinite parallel plates confining an absorbing-emitting medium, *any* two-surface zone system where a nonconvex surface zone is completely surrounded by a second zone (this includes concentric spheres and cylinders),

and the speckled two-surface enclosure. As in the case of a transparent medium, the inverse reflectivity matrix $\mathbf{R}$ is capable of explicit matrix inversion for $M = 2$. This allows derivation of *explicit* algebraic equations for all the required *directed* exchange areas for the clear plus gray WSGG spectral model with $M = 1$ and 2 and $N = 1$.

***The Limiting Case M = 1 and N = 1*** The directed exchange areas for this special case correspond to a single well-mixed gas zone completely surrounded by a single-surface zone $A_1$. Here the reflectivity matrix is a $1 \times 1$ scalar quantity which follows directly from the general matrix equations as $\mathbf{R} = 1/(A_1 - \overline{s_1 s_1} \cdot \rho_1)$. There are *two* WSCC clear plus gray constants $a_1$ and $a_g$ and only *one* unique direct exchange area which satisfies the conservation relation $\overline{s_1 s_1} + \overline{s_1 g} = A_1$. The only two physically meaningful directed exchange areas are those between the surface zone $A_1$ and the gas zone

$$\overleftarrow{\overline{S_1 G}} = \frac{a_g \cdot \varepsilon_1 A_1 \cdot \overline{s_1 g}}{\varepsilon_1 \cdot A_1 + \rho_1 \cdot \overline{s_1 g}} \tag{5-169a}$$

$$\overleftarrow{\overline{G S_1}} = \frac{a_1 \cdot \varepsilon_1 A_1 \cdot \overline{s_1 g}}{\varepsilon_1 \cdot A_1 + \rho_1 \cdot \overline{s_1 g}} \tag{5-169b}$$

The total radiative flux $Q_1$ at surface $A_1$ and the radiative source term $Q_1 = S$ are given by

$$Q_1 = \overleftarrow{\overline{G S_1}} \cdot E_1 - \overleftarrow{\overline{S_1 G}} \cdot E_g \tag{5-169}$$

***Directed Exchange Areas for M = 2 and N = 1*** For this case there are *four* WSGG constants, $a_1$, $a_2$, $a_g$, and $\tau_g$. There is one required value of $K$ that is readily obtained from the equation $K = -\ln(\tau_g)/L_m$, where $\tau_g = \exp(-KL_m)$. For an enclosure with $M = 2$, $N = 1$, and $K \neq 0$, only *three unique* direct exchange areas are required because conservation stipulates $A_1 = \overline{s_1 s_1} + \overline{s_1 s_2} + \overline{s_1 g}$ and $A_2 = \overline{s_2 s_1} + \overline{s_2 s_2} + \overline{s_2 g}$. For $M = 2$ and $N = 1$, the matrix Eqs. (5-118) readily lead to the *general* gray gas matrix solution for $\overline{\mathbf{SS}}$ and $\overleftarrow{\overline{\mathbf{SG}}}$ with $K \neq 0$ as

$$\overline{\mathbf{SS}} = \begin{bmatrix} \varepsilon_1 A_1 - \overline{S_1 S_2} - \overline{S_1 G} & \overline{S_1 S_2} \\ \overline{S_1 S_1} & \varepsilon_2 A_2 - \overline{S_1 S_2} - \overline{S_2 G} \end{bmatrix} \tag{5-170a}$$

where

$$\overline{S_1 S_2} = \varepsilon_1 \varepsilon_2 A_1 A_2 \overline{s_1 s_2} / \det \mathbf{R}^{-1} \tag{5-170b}$$

and

$$\overleftarrow{\overline{\mathbf{SG}}} = \begin{bmatrix} \varepsilon_1 A_1 \left[ (A_2 - \rho_2 \cdot \overline{s_2 s_2}) \cdot \overline{s_1 g} + \rho_2 \cdot \overline{s_1 s_2} \cdot \overline{s_2 g} \right] \\ \varepsilon_2 A_2 \left[ (A_2 - \rho_2 \cdot \overline{s_2 s_2}) \cdot \overline{s_2 g} + \rho_1 \cdot \overline{s_1 s_2} \cdot \overline{s_1 g} \right] \end{bmatrix} / \det \mathbf{R}^{-1} \tag{5-170c}$$

with $\overline{\mathbf{GS}} = \overline{\mathbf{SG}}^{\mathrm{T}}$ and the indicated determinate of $\mathbf{R}^{-1}$ is evaluated algebraically as

$$\det \mathbf{R}^{-1} = (A_1 - \overline{s_1 s_1} \cdot \rho_1) \cdot (A_2 - \overline{s_2 s_2} \cdot \rho_2) - \rho_1 \cdot \rho_2 \cdot \overline{s_1 s_2}^2 \tag{5-170d}$$

For the WSGG clear gas components we denote $\overline{\mathbf{SS}}]_{K=0} \equiv \overline{\mathbf{SS}}_0$ and $\overleftarrow{\overline{\mathbf{SG}}}]_{K=0} \equiv \overleftarrow{\overline{\mathbf{SG}}}_0 = \mathbf{0}$. Finally the WSGG arrays of directed exchange areas are computed simply from $a$-weighted sums of the gray gas total exchange areas as

$$\overline{\mathbf{SS}} = \overline{\mathbf{SS}}_0 \cdot \begin{bmatrix} 1 - a_1 & 0 \\ 0 & 1 - a_2 \end{bmatrix} + \overline{\mathbf{SS}} \cdot \begin{bmatrix} a_1 & 0 \\ 0 & a_2 \end{bmatrix}$$

$$\overleftarrow{\overline{\mathbf{SG}}} = \overline{\mathbf{SG}} \cdot a_g \tag{5-171a,b,c}$$

$$\overleftarrow{\overline{\mathbf{GS}}} = \overline{\mathbf{GS}} \cdot \begin{bmatrix} a_1 & 0 \\ 0 & a_2 \end{bmatrix} \neq \overleftarrow{\overline{\mathbf{SG}}}^{\mathrm{T}}$$

and finally

$$\overleftarrow{\overline{\mathbf{GG}}} = a_g \cdot 4KV - \overleftarrow{\overline{\mathbf{GS}}} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix} \tag{5-171d}$$

The results of this development may be further expanded into algebraic form with the aid of Eq. (5-127) to yield

$$\overleftarrow{\overline{S_2 S_1}} = \frac{\varepsilon_1 \varepsilon_2 A_1 A_2 \cdot \overline{s_2 s_1}]_0 (1 - a_1)}{\varepsilon_1 \varepsilon_2 A_1 A_2 + (\varepsilon_1 A_1 \rho_2 + \varepsilon_2 A_2 \rho_1) \cdot \overline{s_2 s_1}]_0} + \frac{\varepsilon_1 \varepsilon_2 A_1 A_2 \overline{s_2 s_1} \cdot a_1}{\det \mathbf{R}^{-1}} \tag{5-171e}$$

$$\overleftarrow{\overline{\mathbf{SG}}} = \begin{bmatrix} \varepsilon_1 A_1 [(A_2 - \rho_2 \cdot \overline{s_2 s_2}) \cdot \overline{s_1 g} + \rho_2 \cdot \overline{s_1 s_2} \cdot \overline{s_2 g}] \\ \varepsilon_2 A_2 \left[ (A_1 - \rho_1 \cdot \overline{s_1 s_1}) \cdot \overline{s_2 g} + \rho_1 \cdot \overline{s_1 s_2} \cdot \overline{s_1 g} \right] \end{bmatrix} \cdot a_g / \det \mathbf{R}^{-1} \tag{5-171f}$$

and

$$\overleftarrow{\overline{\mathbf{GS}}} = [\overleftarrow{\overline{G S_1}} \quad \overleftarrow{\overline{G S_1}}] \tag{5-171g}$$

whose matrix elements are given by $\overleftarrow{\overline{G S_1}} \equiv \varepsilon_1 A_1 \left[ (A_2 - \rho_2 \cdot \overline{s_1 s_1}) \cdot \overline{s_1 g} + \rho_2 \cdot \overline{s_1 s_2} \cdot \overline{s_2 g} \right] a_1 / \det \mathbf{R}^{-1}$ and $\overleftarrow{\overline{G S_2}} \equiv \varepsilon_2 A_2 \left[ (A_1 - \rho_1 \cdot \overline{s_1 s_1}) \cdot \overline{s_2 g} + \rho_1 \cdot \overline{s_1 s_2} \cdot \overline{s_1 g} \right] a_2 / \det \mathbf{R}^{-1}$. Derivation of the scalar (algebraic) forms for the directed exchange areas here is done primarily for illustrative purposes. Computationally, the only advantage is to obviate the need for a digital computer to evaluate a $[2 \times 2]$ matrix inverse.

***Allowance for an Adiabatic Refractory with N = 1 and M = 2*** Set $N = 1$ and $M = 2$, and let zone 2 represent the refractory surface. Let $Q_2 = 0$ and $\varepsilon_2 \neq 0$; it then follows that we may define a *refractory-aided* directed exchange area $\overleftarrow{\overline{S_1 G}}_R$ by

$$\overleftarrow{\overline{S_1 G}}_R = \overleftarrow{\overline{S_1 G}} + \frac{\overleftarrow{\overline{S_1 S}}_2 \cdot \overleftarrow{\overline{S_2 G}}}{\overleftarrow{\overline{S_1 S}}_2 + \overleftarrow{\overline{S_2 G}}} \tag{5-172a}$$

Assuming radiative equilibrium, the emissive power of the refractory may also be calculated from the companion equation

$$E_2 = \frac{\overleftarrow{\overline{S_2 S}}_1 \cdot E_1 + \overleftarrow{\overline{S_2 G}} \cdot E_g}{\overleftarrow{\overline{S_2 S}}_1 + \overleftarrow{\overline{S_2 G}}} \tag{5-172b}$$

In this circumstance, *all* the radiant energy originating in the gas volume is transferred to the *sole* sink zone $A_1$. Equation (5-172*a*) is thus tantamount to the statement that $Q_1 = S'$ or that the net emission from the source ultimately must arrive at the sink. Notice that if $\varepsilon_1 = 0$, Eq. (5-172*a*) leads to a physically incongruous statement since *all* the directed exchange areas would vanish and *no sink* would exist. Even for the simple case of $M = 2$ and $N = 1$, the algebraic complexity of Eqs. (5-171) suggests that *numerical matrix manipulation* of directed exchange areas is preferred rather than calculations using algebraic formulas.

**Engineering Approximations for Directed Exchange Areas** Use of the preceding equations for directed exchange areas with $M = 2$ and $N = 1$ and the WSGG clear plus gray gas spectral approximation requires knowledge of three independent direct exchange areas. It also formally requires evaluation of three WSGG weighting constants $a_1$, $a_2$, and $a_g$ with respect to the three temperatures $T_1$, $T_2$, and $T_g$. Further simplifications may be made by assuming that radiant transfer for the *entire* enclosure is characterized by the *single* mean beam length $L_M = 0.88 \cdot 4 \cdot V/A$. The requisite direct exchange areas are then approximated by

$$\overline{\mathbf{ss}} = \tau_g \begin{bmatrix} A_1 \cdot F_{1,1} & A_1 \cdot F_{1,2} \\ A_2 \cdot F_{2,1} & A_2 \cdot F_{2,2} \end{bmatrix} \tag{5-173a}$$

with

$$\overline{\mathbf{sg}} = (1 - \tau_g) \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} \tag{5-173b}$$

and for the particular case of a speckled enclosure

$$\overline{\mathbf{ss}} = \frac{\tau_g}{A_1 + A_2} \begin{bmatrix} A_1^2 & A_1 \cdot A_2 \\ A_1 \cdot A_2 & A_2^2 \end{bmatrix} \tag{5-174a}$$

also with

$$\overline{\mathbf{sg}} = (1 - \tau_g) \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} \tag{5-174b}$$

where again $\tau_g$ is obtained from the WSGG fit of gas emissivity. These approximate formulas clearly obviate the need for *exact* values of the direct exchange areas and may be used in conjunction with Eqs. (5-171).

For engineering calculations, an additional simplification is sometimes warranted. Again characterize the system by a single mean beam length $L_M = 0.88 \cdot 4 \cdot V/A$ and employ the *identical* value of $\tau_g = KL_M$ for all surface-gas transfers. The three $a$ constants *might* then be obtained by a WSGG data-fitting procedure for gas emissivity and gas absorptivity which utilizes the three different temperatures $T_g$, $T_1$, and $T_2$. For engineering purposes we choose a simpler method, however. First calculate values of $\varepsilon_g$ and $\alpha_{g1}$ for gas temperature $T_g$ with respect to the *dominant* (sink) temperature $T_1$. The *net* radiative flux between an isothermal gas mass at temperature $T_g$ and a

black isothermal bounding surface $A_1$ at temperature $T_1$ (the sink) is given by Eq. (5-138) as

$$Q_{1,g} = A_1\sigma\left(\alpha_{g,1}T_1^4 - \varepsilon_g T_g^4\right) \tag{5-175}$$

It is clear that transfer from the gas to the surface and transfer from the surface into the gas are characterized by two different constants of proportionality, $\varepsilon_g$ and $\alpha_{g,1}$, respectively. To allow for the difference between gas emissivity and absorptivity, it proves convenient to introduce a single *mean gas emissivity* defined by

$$\sigma\left[\varepsilon_g T_g^4 - \alpha_{g,1}T_1^4\right] = \varepsilon_m\sigma\left(T_g^4 - T_1^4\right) \tag{5-176a}$$

or

$$\varepsilon_m = \frac{\varepsilon_g - \alpha_{g,1}(T_1/T_g)^4}{1-(T_1/T_g)^4} \tag{5-176b}$$

The calculation then proceeds by computing *two* values of $\varepsilon_m$ at the given $T_g$ and $T_1$ temperature pair and the two values of $pL_M$ and $2pL_M$. We thereby obtain the expression $\varepsilon_m = \alpha_m(1-\tau_m)$. It is then assumed that $a_1 = a_2 = a_g = a_m$ for use in Eqs. (5-171). This simplification may be used for $M > 2$ as long as $N = 1$. This simplification is illustrated in Example 5-13.

***Example 5-13 WSGG Clear Plus Gray Gas Emissivity Calculations*** Methane is burned to completion with 20 percent excess air (50 percent relative humidity at 298 K or 0.0088 mol water/mol dry air) in a furnace chamber of floor dimensions $3 \times 10$ m and height 5 m. The entire surface area of the enclosure is a gray sink with emissivity of 0.8 at 1000 K. The confined gas is well stirred at 1500 K. Evaluate the clear plus gray WSGG constants and the mean effective gas emissivity, and calculate the average radiative flux density to the enclosure surface.

*Two-zone model, $M = 1$, $N = 1$:* A single volume zone completely surrounded by a single sink surface zone.

*Function definitions:*

Gas emissivity: $\varepsilon_g F(T_g, pL, b, n) = b\cdot(pL - 0.015)^n \div T_g$ Eq. (5-140*a*)

Gas absorptivity: $$\alpha_{g1}F(T_g, T_1, pL, b, n) = \frac{\varepsilon_g F(T_1, pL\cdot T_1/T_g, b, n)\cdot T_1\cdot(T_g/T_1)^{0.5}}{T_1}$$

Eq. (5-141)

Mean effective gas emissivity: $$\varepsilon_{gm}(\varepsilon_g, \alpha_g, T_g, T_1) = \frac{\varepsilon_g - \alpha_g\cdot(T_1/T_g)^4}{1-(T_1/T_g)^4}$$

Eq. (5-176*a*)

*Physical constants:* $\sigma \equiv 5.670400\times10^{-8}\ \dfrac{\text{W}}{\text{m}^2\cdot\text{K}^4}$

*Enclosure input parameters:*

$T_g = 1500$ K $\quad T_1 = 1000$ K $\quad A_1 = 190$ m$^2$ $\quad V = 150$ m$^3$

$\varepsilon_1 = 0.8$ $\quad \rho_1 = 1-\varepsilon_1$ $\quad \rho_1 = 0.2$

$E_1 = \sigma\cdot T_1^4$ $\quad E_g = \sigma\cdot T_g^4$ $\quad E_1 = 56.70\ \dfrac{\text{kW}}{\text{m}^2}$ $\quad E_g = 287.06\ \dfrac{\text{kW}}{\text{m}^2}$

Stoichiometry yields the following mole table:

Mole Table: Basis 1.0 mol Methane

| Species | MW | Moles in | Mass in | Moles out | *Y* out |
|---|---|---|---|---|---|
| $CH_4$ | 16.04 | 1.00000 | 16.04 | 0.00000 | 0.00000 |
| $O_2$ | 32.00 | 2.40000 | 76.80 | 0.40000 | 0.03193 |
| $N_2$ | 28.01 | 9.02857 | 252.93 | 9.02857 | 0.72061 |
| $CO_2$ | 44.01 | 0.00000 | 0.00 | 1.00000 | 0.07981 |
| $H_2O$ | 18.02 | 0.10057 | 1.81 | 2.10057 | 0.16765 |
| Totals | 138.08 | 12.52914 | 347.58 | 12.52914 | 1.00000 |

$p_W = 0.16765$ atm $\quad p_C = 0.07981$ atm $\quad p = p_W + p_C$ $\quad p = 0.2475$ atm

$p_W \div p_C = 2.101$

The mean beam length is approximated by

$$L_M = 0.88\cdot4\cdot V \div A_1 \qquad L_M = 2.7789\ \text{m}$$

and $pL_M = p\cdot L_M$ $\quad pL_M = 0.6877$ atm·m $\quad pL_M = 0.6877$

The gas emissivities and absorptivities are then calculated from the two-constant correlation in Table 5-6 (column 5 with $p_W/p_C = 2.0$) as follows:

$\varepsilon_{g1} = \varepsilon_g F(1500, pL_M, 540, 0.42)$ $\quad \varepsilon_{g1} = 0.3048$

$\varepsilon_{g2} = \varepsilon_g F(1500, 2pL_M, 540, 0.42)$ $\quad \varepsilon_{g2} = 0.4097$

$\alpha_{g11} = \alpha_{g1} F(1500, 1000, pL_M, 444, 0.34)$ $\quad \alpha_{g11} = 0.4124$

$\alpha_{g12} = \alpha_{g1} F(1500, 1000, 2pL_M, 444, 0.34)$ $\quad \alpha_{g12} = 0.5250$

*Case (a): Compute Flux Density Using Exact Values of the WSGG Constants*

$\tau_g = \dfrac{\varepsilon_{g2}}{\varepsilon_{g1}} - 1$ $\quad a_g = \dfrac{\varepsilon_{g1}}{1-\tau_g}$ $\quad \varepsilon_g = a_g\cdot(1-\tau_g)$ $\quad a_{g1} = \dfrac{\alpha_{g11}}{1-\tau_g}$

$\tau_g = 0.3442$ $\quad a_g = 0.4647$ $\quad \varepsilon_g = 0.3048$ $\quad a_{g1} = 0.6289$

and the WSGG gas absorption coefficient (which is necessary for calculation of direct exchange areas) is calculated as

$$K_1 = \frac{-(\ln\tau_g)}{L_M} \quad \text{or} \quad K_1 = 0.3838\,\frac{1}{\text{m}}$$

*Compute directed exchange areas:*

Given $s_{1g} = (1-\tau_g)\cdot A_1$ $\quad = 124.61$ m$^2$

Eqs. (5-169) yield

$$\text{DS1G} = \frac{a_g\cdot\varepsilon_1\cdot A_1\cdot s_1 g}{\varepsilon_1\cdot A_1 + \rho_1\cdot s_1 g} \qquad \text{DGS1} = \frac{a_{g1}\cdot\varepsilon_1\cdot A_1\cdot s_1 g}{\varepsilon_1\cdot A_1 + \rho_1\cdot s_1 g}$$

DS1G = 49.75 m$^2$ $\quad$ DGS1 = 67.32 m$^2$

And finally the gas to sink flux density is computed as

$Q_1 = \text{DGS1}\cdot E_1 - \text{DS1G}\cdot E_g$ $\quad Q_1 = -10{,}464.0$ kW $\quad \dfrac{Q_1}{A_1} = -55.07\ \dfrac{\text{kW}}{\text{m}^2}$

*Case (b): Compute the Flux Density Using Mean Effective Gas Emissivity Approximation*

$\varepsilon_{gm1} = \varepsilon_{gm}(\varepsilon_{g1}, \alpha_{g11}, T_g, T_1)$ $\quad \varepsilon_{gm1} = 0.2783$

$\varepsilon_{gm2} = \varepsilon_{gm}(\varepsilon_{g2}, \alpha_{g12}, T_g, T_1)$ $\quad \varepsilon_{gm2} = 0.3813$

$\tau_m = \dfrac{\varepsilon_{gm2}}{\varepsilon_{gm1}} - 1$ $\quad a_m = \dfrac{\varepsilon_{gm1}}{1-\tau_m}$ $\quad \varepsilon_{gm} = a_m\cdot(1-\tau_m)$

$\tau_m = 0.3701$ $\quad a_m = 0.4418$ $\quad \varepsilon_{gm} = 0.2783$ $\quad s_1 g_m = (1-\tau_m)\cdot A_1$

$\text{S1G}_m = \dfrac{\varepsilon_1\cdot a_m\cdot s_1 g_m\cdot A_1}{\varepsilon_1\cdot A_1 + \rho_1\cdot s_1 g_m}$ $\quad \text{S1G}_m = 45.68$ m$^2$ $\quad s_1 g_m = 119.67$ m$^2$

$$q_{1m} = \frac{\text{SIG}_m\cdot(E_1 - E_g)}{A_1} \qquad q_{1m} = -55.38\ \frac{\text{kW}}{\text{m}^2}$$

compared with $\dfrac{Q_1}{A_1} = -55.07\ \dfrac{\text{kW}}{\text{m}^2}$

The computed flux densities are nearly equal because there is a *single* sink zone $A_1$.

(This example was developed as a MATHCAD 15 worksheet. MATHCAD is a registered trademark of Parametric Technology Corporation.)

## ENGINEERING MODELS FOR FUEL-FIRED FURNACES

Modern digital computation has evolved methodologies for the design and simulation of fuel-fired combustion chambers and furnaces which incorporate virtually *all* the transport phenomena, chemical kinetics, and thermodynamics studied by chemical engineers. Nonetheless, there still exist many furnace design circumstances where such computational sophistication is not always appropriate. Indeed, a practical need still exists for simple engineering models for purposes of conceptual process design, cost estimation, and the correlation of test performance data. In this section, the zone method is used to develop perhaps the simplest *computational template* available to address some of these practical engineering needs.

**Input/Output Performance Parameters for Furnace Operation** The term *firing density* is typically used to define the basic *operational input parameter* for fuel-fired furnaces. In practice, firing density is often defined as the input fuel feed rate per unit area (or volume) of furnace heat-transfer surface. Thus defined, the firing density is a *dimensional quantity*. Since the feed enthalpy rate $\dot{H}_f$ is proportional to the feed rate, we employ the sink area $A_1$ to define a *dimensionless firing density* as $N_{FD} = \dot{H}_f/\sigma T_{\text{Ref}}^4\cdot A_1$ where $T_{\text{Ref}}$ is some characteristic reference temperature. In practice, gross furnace

*output performance* is often described by using one of several *furnace efficiencies*. The most common is the *gas* or *gas-side furnace efficiency* $\eta_g$, defined as the total enthalpy transferred to furnace internals divided by the total available feed enthalpy. Here the total available feed enthalpy is defined to include the lower heating value (LHV) of the fuel plus any air preheat above an arbitrary ambient datum temperature. Under certain conditions the definition of furnace efficiency reduces to some variant of the simple equation $\eta_g = (T_{\text{Ref}} - T_{\text{out}})/(T_{\text{Ref}} - T_0)$ where again $T_{\text{Ref}}$ is some reference temperature appropriate to the system in question.

**The Long Plug Flow Furnace (LPFF) Model** If a combustion chamber of cross-sectional area $A_{\text{duct}}$ and perimeter $P_{\text{duct}}$ is sufficiently long in the direction of flow, compared to its mean hydraulic radius $L >> R_h = A_{\text{duct}}/P_{\text{duct}}$, then the radiative flux from the gas to the bounding surfaces can sometimes be adequately characterized by the *local* gas temperature. The physical rationale for this is that the *magnitudes* of the opposed upstream and downstream radiative fluxes through a cross section transverse to the direction of flow are sufficiently large as to substantially balance each other. Such a situation is not unusual in engineering practice and is referred to as the *long furnace approximation*. As a result, the radiative flux from the gas to the bounding surface may then be approximated using *two-dimensional* directed exchange areas $\overline{S_1G}/A_1 \equiv \dfrac{\partial(\overline{S_1G})}{\partial A_1}$, calculated using methods as described previously.

Consider a duct of length $L$ and perimeter $P$, and assume plug flow in the direction of flow $z$. Further assume high-intensity mixing at the entrance end of the chamber such that combustion is *complete* as the combustion products enter the duct. The duct then acts as a long heat exchanger in which heat is transferred to the walls at constant temperature $T_1$ by the combined effects of radiation and convection. Subject to the long furnace approximation, a differential energy balance on the duct then yields

$$\dot{m}\overline{C}_p \frac{dT_g}{dz} = P\left[\frac{\overline{S_1G}}{A_1}\sigma\left(T_g^4 - T_1^4\right) + h(T_g - T_1)\right] \tag{5-177}$$

where $\dot{m}$ is the mass flow rate and $\overline{C}_p$ is the heat capacity per unit mass. Equation (5-177) is nonlinear with respect to temperature. To solve Eq. (5-177), first linearize the convective heat-transfer term in the right-hand side with the approximation $\Delta T = T_2 - T_1 \approx \left(T_2^4 - T_1^4\right)/4\overline{T}_{1,2}^3$ where $\overline{T}_{1,2} = (T_1 + T_2)/2$. This linearization underestimates $\Delta T$ by no more than 5 percent when $T_2/T_1 < 1.59$. Integration of Eq. (5-177) then leads to the solution

$$\ln\left[\frac{(T_{g,\text{out}} - T_1)(T_{g,\text{in}} + T_1)}{(T_{g,\text{out}} + T_1)(T_{g,\text{in}} - T_1)}\right] + 2.0\tan^{-1}\left[\frac{(T_{g,\text{in}} - T_{g,\text{out}})\cdot T_1}{\left(T_1^2 + T_{g,\text{in}}\cdot T_{g,\text{out}}\right)}\right] = -\frac{4}{D_{\text{eff}}} \tag{5-178}$$

The long plug flow furnace (LPFF) model is described by only two dimensionless parameters, namely, an *effective* firing density and a dimensionless sink temperature

$$D_{\text{eff}} = \frac{N_{\text{FD}}}{\left(\dfrac{\overline{S_1G}}{A_1}\right) + N_{\text{CR}}} \quad \text{and} \quad \Theta_1 = T_1/T_{g,\text{in}} \tag{5-178a,b}$$

Here the dimensionless firing density $N_{\text{FD}}$ and a dimensionless convection-radiation (CR) number $N_{\text{CR}}$ are defined as

$$N_{\text{FD}} = \frac{\dot{m}\overline{C}_p}{\sigma\cdot T_1^3 A_1} \quad \text{and} \quad N_{\text{CR}} = \frac{h}{4\sigma\overline{T}_{g,1}^3} \tag{5-178c,d}$$

where $A_1 = PL$ is the duct surface area (the sink area), and $\overline{T}_{g1} = (\overline{T}_g + T_1)/2$ is treated as a constant. This definition of the effective dimensionless firing density $D_{\text{eff}}$ clearly delineates the relative roles of radiation and convective heat transfer since radiation and convection are identified as *parallel* (*electrical*) *conductances*.

In analogy with a conventional heat exchanger, Eq. (5-178) displays two asymptotic limits. First define

$$\eta_f = \frac{T_{g,\text{in}} - T_{g,\text{out}}}{T_{g,\text{in}} - T_1} = 1 - \frac{T_{g,\text{out}} - T_1}{T_{g,\text{in}} - T_1} \tag{5-179}$$

as the efficiency of the long furnace. The two asymptotic limits with respect to firing density are then given by

$$D_{\text{eff}} << 1 \qquad T_{g,\text{out}} \to T_1 \qquad \eta_f \to 1 \tag{5-179a}$$

and

$$D_{\text{eff}} >> 1 \qquad T_{g,\text{out}} \to T_{g,\text{in}}$$

$$\eta_f \to \frac{4}{D_{\text{eff}}\left[1 - \dfrac{R-1}{R+1} - 2\dfrac{R-1}{R^2+1}\right]} \tag{5-179b}$$

where $R \equiv T_{g,\text{in}}/T_1 = 1/\Theta_1$.

For low firing rates, the exit temperature of the furnace gases approaches that of the sink; i.e., sufficient residence time is provided for nearly complete heat removal from the gases. When the combustion chamber is overfired, only a small fraction of the available feed enthalpy heat is removed within the furnace. The exit gas temperature then remains essentially that of the inlet temperature, and the furnace efficiency tends asymptotically to zero.

It is important to recognize that the two-dimensional exchange area $\dfrac{\overline{S_1G}}{A_1} \equiv \dfrac{\partial(\overline{S_1G})}{\partial A_1}$ in the definition of $D_{\text{eff}}$ can represent a *lumped* two-dimensional exchange area of somewhat arbitrary complexity. This quantity also contains *all* the information concerning furnace geometry and gas and surface emissivities. To compare the relative importance of radiation with respect to convection, suppose $h$ = 10 Btu/(h·ft²·°R) = 0.057 kW/(K·m²) and $\overline{T}_{g,1}$ = 1250 K, which leads to the numerical value $N_{\text{CR}} = 0.128$; or, in general, $N_{\text{CR}}$ is of order 0.1 or less. The importance of the radiation contribution is estimated by bounding the magnitude of the dimensionless directed exchange area. For the case of a single-gas zone completely surrounded by a black enclosure, Eq. (5-169) reduces to simply $\overline{S_1G}/A_1 = \varepsilon_g \le 1.0$, and it is evident that the magnitude of the radiation contribution never exceeds unity. At high temperatures, radiative effects can easily dominate other modes of heat transfer by an order of magnitude or more. When mean beam length calculations are employed, use $L_M/D = 0.94$ for a cylindrical cross section of diameter $D$, and

$$L_{M0} = \frac{2H\cdot W}{H + W}$$

for a rectangular duct of height $H$ and width $W$.

**The Well-Stirred Combustion Chamber (WSCC) Model** Many combustion chambers utilize high-momentum feed conditions with associated high-intensity mixing. The *well-stirred combustion chamber (WSCC) model* assumes a single-gas zone and high-intensity mixing. Moreover, combustion and heat transfer are visualized to occur *simultaneously* within the combustion chamber. The WSCC model is characterized by some *six* temperatures which are listed in rank order as $T_0$, $T_{\text{air}}$, $T_1$, $T_e$, $T_g$, and $T_f$. Even though the combustion chamber is well mixed, it is *arbitrarily* assumed that the gas temperature within the enclosure $T_g$ is *not necessarily equal* to the gas exit temperature $T_e$. Rather the two temperatures are related by the simple relation $\Delta T_{ge} \equiv T_g - T_e$, where $\Delta T_{ge} \approx 170$ K (as a representative value) is introduced as an *adjustable parameter* for the purposes of data fitting and to make allowance for nonideal mixing. In addition, $T_0$ is the ambient temperature, $T_{\text{air}}$ is the air preheat temperature, and $T_f$ is a *pseudoadiabatic flame temperature*, as will be explained in the following development. The condition $\Delta T_{ge} \equiv 0$ is intended to simulate a perfect *continuous well-stirred reactor* (CSTR).

***Dimensional WSCC Approach*** A macroscopic enthalpy balance on the well-stirred combustion chamber is written as

$$-\Delta H = H_{\text{in}} - H_{\text{out}} = Q_{\text{rad}} + Q_{\text{con}} + Q_{\text{ref}} \tag{5-180}$$

Here $Q_{\text{rad}} = \overline{S_1G}_R\sigma\left(T_g^4 - T_1^4\right)$ represents radiative heat transfer to the sink (with due allowance for the presence of any refractory surfaces). And the two terms $Q_{\text{con}} = h_1A_1(T_g - T_1)$ and $Q_{\text{ref}} = UA_R(T_g - T_0)$ formulate the convective heat transfer to the sink and *through* the refractory, respectively.

Formulation of the left-hand side of Eq. (5-180) requires representative thermodynamic data and information on the combustion stoichiometry. In particular, the former includes the lower heating value of the fuel, the temperature-dependent molal heat capacity of the inlet and outlet streams, and the air preheat temperature $T_{\text{air}}$. It proves especially convenient now to introduce the definition of a pseudoadiabatic flame temperature $T_f$, which is *not* the true adiabatic flame temperature, but rather is an adiabatic flame temperature based on the average heat capacity of the combustion products over the temperature interval $T_0 < T < T_e$. The calculation of $T_f$ does not allow for dissociation of chemical species and is a surrogate for the total enthalpy content of the input fuel-air mixture. It also proves to be an especially convenient system *reference temperature*. Details for the calculation of $T_f$ are illustrated in Example 5-14.

In terms of this particular definition of the pseudoadiabatic flame temperature $T_f$, the total enthalpy change and gas efficiency are given simply as

$$\Delta H = \dot{H}_f - \dot{m}\cdot\overline{C}_{P,\text{Prod}}(T_e - T_0) = \dot{m}\overline{C}_{P,\text{Prod}}(T_f - T_e) \tag{5-181a,b}$$

where $\dot{H}_f \equiv \dot{m}\cdot\overline{C}_{P,\text{Prod}}(T_f - T_0)$ and $T_e = T_g - \Delta T_{ge}$. This particular definition of $T_f$ leads to an especially convenient formulation of furnace efficiency:

$$\eta_g = Q/\dot{H}_f = \frac{\dot{m}\cdot\overline{C}_{P,\text{Prod}}(T_f - T_e)}{\dot{m}\cdot\overline{C}_{P,\text{Prod}}(T_f - T_0)} = \frac{T_f - T_e}{T_f - T_0} \tag{5-182}$$

In Eq. (5-182), $\dot{m}$ is the total mass flow rate and $\overline{C}_{P,\text{Prod}}$ [J/(kg·K)] is defined as the *average heat capacity* of the product stream over the temperature interval $T_0 < T < T_e$.

The final overall enthalpy balance is then written as

$$\dot{m}\cdot\overline{C}_{P,\text{Prod}}(T_f - T_e) = \overline{S_1 G}_R \sigma\left(T_g^4 - T_1^4\right) + h_1 A_1 (T_g - T_1) + U A_R (T_g - T_0) \tag{5-183}$$

with $T_e = T_g - \Delta T_{ge}$.

Equation (5-183) is a nonlinear algebraic equation which may be solved by a variety of iterative methods. The *sole* unknown quantity, however, in Eq. (5-183) is the gas temperature $T_g$. It should be recognized, in particular, that $T_f$, $T_e$, $\overline{C}_{P,\text{Prod}}$, and the directed exchange area are all explicit functions of $T_g$. The method of solution of Eq. (5-183) is demonstrated in detail in Example 5-14.

***Dimensionless WSCC Approach*** In Eq. (5-183), assume the convective heat loss through the refractory is negligible, and linearize the convective heat transfer to the sink. These approximations lead to the result

$$\dot{m}\cdot\overline{C}_{P,\text{Prod}}(T_f - T_g + \Delta T_{ge}) = \overline{S_1 G}_R \sigma\left(T_g^4 - T_1^4\right) + h_1 A_1 \left(T_g^4 - T_1^4\right)/4\overline{T}_{g,1}^3 \tag{5-184}$$

where $\overline{T}_{g,1} = (T_g + T_1)/2$ is some characteristic average temperature which is taken as constant. Now normalize all temperatures based on the pseudoadiabatic temperature as in $\Theta_i = T_i/T_f$. Equation (5-184) then leads to the dimensionless equation

$$D_{\text{eff}}(1 - \Theta_g + \Delta^*) = (\Theta_g^4 - \Theta_1^4) \tag{5-185}$$

where again $D_{\text{eff}} = N_{\text{FD}}/(\overline{S_1 G}_R/A_1 + N_{\text{CR}})$ is defined *exactly* as in the case of the LPFF model, with the proviso that the WSCC dimensionless firing density is defined here as $N_{\text{FD}} = \dot{m}\overline{C}_{P,\text{Prod}}/\left(\sigma T_f^3 \cdot A_1\right)$. The dimensionless furnace efficiency follows directly from Eq. (5-182) as

$$\eta_g = \frac{1 - \Theta_e}{1 - \Theta_0} = \frac{1 - \Theta_g + \Delta^*}{1 - \Theta_0} \tag{5-186a}$$

We also define a *reduced furnace efficiency* $\eta_g'$ as

$$\eta_g' \equiv (1 - \Theta_0)\cdot\eta_g = 1 - \Theta_g + \Delta^* \tag{5-186b}$$

Since Eq. (5-186*b*) may be rewritten as $\Theta_g = (1 + \Delta^* - \eta_g')$ combination of Eqs. (5-185) and (5-186*b*) yields the final result

$$D_{\text{eff}}\cdot\eta_g' = (1 + \Delta^* - \eta_g')^4 - \Theta_1^4 \tag{5-187}$$

Equation (5-187) provides an *explicit* relation between the modified furnace efficiency and the effective firing density directly in which the gas temperature is eliminated.

Equation (5-187) has two asymptotic limits

$$\begin{gathered} D_{\text{eff}} \ll 1 \qquad \Theta_g \to \Theta_1 \\ \eta_g' \to 1 - \Theta_1 + \Delta^* \end{gathered} \tag{5-188a}$$

and

$$\begin{gathered} D_{\text{eff}} \gg 1 \quad \Theta_g \to 1 + \Delta^* \quad \text{and} \quad \Theta_e \to 1 \\ \eta_g' \to \frac{(1 + \Delta^*)^4 - \Theta_1^4}{D_{\text{eff}} + 4(1 + \Delta^*)^3} \end{gathered} \tag{5-188b}$$

Figure 5-21 is a plot of $\eta_g'$ versus $D_{\text{eff}}$ computed from Eq. (5-187) for the case $\Delta^* = 0$.

The asymptotic behavior of Eq. (5-189) mirrors that of the LPFF model. Here, however, for low firing densities, the exit temperature of the furnace exit gases approaches $\Theta_e = \Theta_1 - \Delta^*$ rather than the sink temperature. Moreover, for $D_{\text{eff}} << 1$ the reduced furnace efficiency adopts the constant value $\eta_g' = 1 - \Theta_e = 1 + \Delta^* - \Theta_1$. Again at very high firing rates, only a very small fraction of the available feed enthalpy heat is recovered within the furnace. Thus the exit gas temperature remains nearly unchanged from the pseudoadiabatic flame temperature [$T_e \approx T_f$], and the gas-side efficiency necessarily approaches zero.

***Example 5-14 WSCC Furnace Model Calculations*** Consider the furnace geometry and combustion stoichiometry described in Example 5-13. The end-fired furnace is 3 m wide, 5 m tall, and 10 m long. Methane at a firing rate of 2500 kg/h is burned to completion with 20 percent excess air which is preheated to 600°C. The speckled furnace model is to be used. The sink (zone 1) occupies 60 percent of the total interior furnace area and is covered with two rows of 5-in (0.127-m) tubes mounted on equilateral centers with a center-to-center distance of twice the tube diameter. The sink temperature is 1000 K, and the tube emissivity is 0.7. Combustion products discharge from a 10-m$^2$ duct in the roof which is also covered with tube screen and is

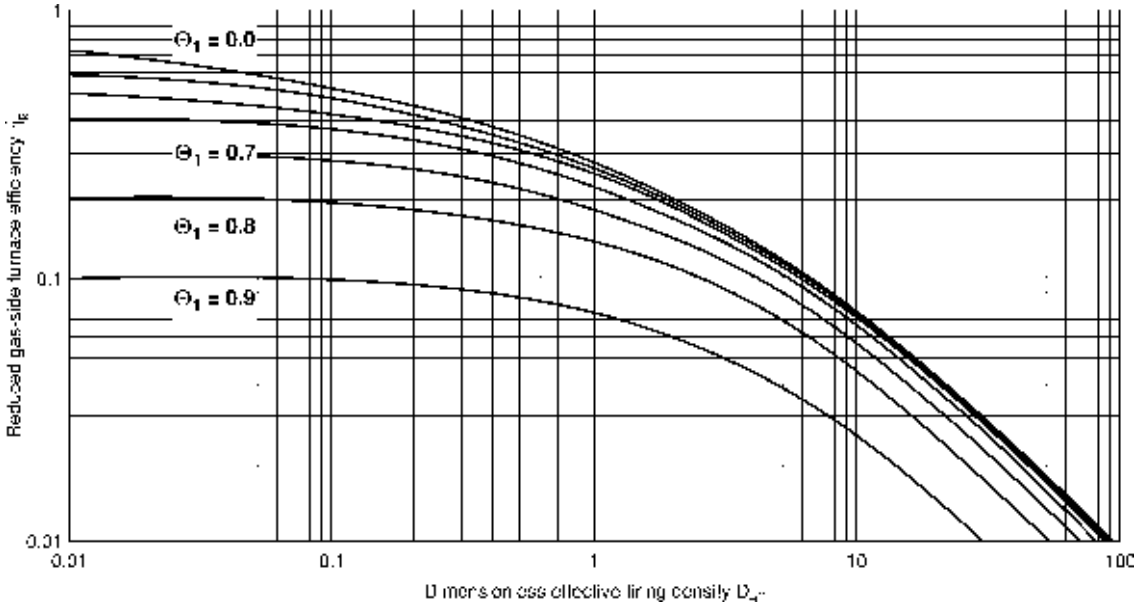

**FIG. 5-21** Reduced gas-side furnace efficiency versus effective firing density for well-stirred combustion chamber model. $\Delta^* = 0$, $\Theta_1 = 0.0, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9$.

to be considered part of the sink. The refractory (zone 2) with emissivity 0.6 is radiatively adiabatic but demonstrates a small convective heat loss to be calculated with an overall heat-transfer coefficient $U$. Compute all unknown furnace temperatures, the gas-side furnace efficiency, and the mean heat flux density through the tube surface. Use the *dimensional* solution approach for the well-stirred combustor model, and compare computed results with the *dimensionless* WSCC and LPFF models. Computed values for mean equivalent gas emissivity obtained from Eq. (5-174*b*) and Table 5-6 for $T_g = 2000$ K for $L_M = 2.7789$ m and $T_1 = 1000$ K are found to be

$T_g = 1500$ K $\quad a_m = 0.44181 \quad \tau_m = 0.37014 \quad \varepsilon_m = 0.27828$

$T_g = 2000$ K $\quad a_m = 0.38435 \quad \tau_m = 0.41844 \quad \varepsilon_m = 0.22352$

Over this temperature range the gas emissivity may be calculated by linear interpolation. Additional heat-transfer and thermodynamic data are supplied in context.

*Three-zone speckled furnace model, $M = 2$ and $N = 1$:*
Zone 1: Sink (60 percent of total furnace area)
Zone 2: Refractory surface (40 percent of total furnace area)
*Physical constants:*

$$\sigma \equiv 5.670400 \times 10^{-8}\ \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4}$$

*Linear interpolation function for mean effective gas emissivity constants:*

$$\text{LINTF}(T, Y2, Y1) = \frac{Y1 \cdot (2000\ \text{K} - T) + Y2 \cdot (T - 1500\ \text{K})}{500\ \text{K}} \quad (1500\ \text{K} < T < 2000\ \text{K})$$

*Enclosure input parameters:*

$$V_{\text{tot}} = 150\ \text{m}^3 \quad A_{\text{tot}} = 190\ \text{m}^2 \quad C_1 = 6 \quad C_2 = 1 - C_1$$
$$A_1 = C_1 \cdot A_{\text{tot}} \quad A_2 = C_2 \cdot A_{\text{tot}} \quad D_{\text{tube}} = 0.127\ \text{m}$$

*Direct exchange areas for WSGG clear gas component (temperature-independent):*

$$F = \begin{pmatrix} C_1 & C_2 \\ C_1 & C_2 \end{pmatrix} \quad AI = \begin{pmatrix} A_1 & 0 \\ 0 & A_2 \end{pmatrix} \quad ss_1 = AI \cdot F \quad ss_1 = \begin{pmatrix} 68.40 & 45.60 \\ 45.60 & 30.40 \end{pmatrix} \text{m}^2$$

*Equivalent gray plane emissivity calculations for sink:*

$\varepsilon_{\text{tube}} = 0.7 \quad F_{\text{bar}} = 0.987$ ( from Fig. 5-11, curve 6 with ratio = 2.0)

$$\varepsilon_{1\text{eq}} = \frac{1}{\left(\frac{1}{1} - 1\right) + 2 \cdot \frac{D_{\text{tube}}}{2 \cdot \pi \cdot D_{\text{tube}}} \cdot \left(\frac{1}{\varepsilon_{\text{tube}}} - 1\right) + \frac{1}{F_{\text{bar}}}} = 0.86988$$

$$\varepsilon_1 = \varepsilon_{1\text{eq}} \quad \varepsilon_2 = 0.6 \quad \varepsilon I = \begin{pmatrix} \varepsilon_1 & 0 \\ 0 & \varepsilon_2 \end{pmatrix} \quad \rho I = \text{identity}\ (2) - \varepsilon I$$

*Total exchange areas for WSGG clear gas component:*

$$R_1 = (AI - ss_1 \cdot \rho I)^{-1} \quad SS_1 = \varepsilon I \cdot AI \cdot R_1 \cdot ss_1 \cdot \varepsilon I \quad SS_1 = \begin{pmatrix} 67.93 & 31.24 \\ 31.24 & 14.36 \end{pmatrix} \text{m}^2$$

*Temperature and emissive power input data:*

$$T_1 = 1000.0\ \text{K} \quad T_{\text{air}} = 873.15\ \text{K}$$
$$T_0 = 298.15\ \text{K} \quad \Delta T_{ge} = 170\ \text{K} \quad E_1 = \sigma \cdot T_1^4 \quad E_1 = 56.704\ \frac{\text{kW}}{\text{m}^2}$$

*Mean beam length calculations:*

$$L_{M0} = 4 \cdot \frac{V_{\text{tot}}}{A_{\text{tot}}} \quad L_{M0} = 3.1579\ \text{m} \quad L_M = 0.88 L_{M0} \quad L_M = 2.7789\ \text{m}$$

*Stoichiometric and thermodynamic input data:*

$$\Sigma\,\text{Mol} = 12.52914 \quad \text{LHV} = 191{,}760\ \frac{\text{cal}}{\text{mol}} \quad \text{MCH4}_{\text{air}} = 7.31\ \frac{\text{cal}}{\text{mol} \cdot \text{K}}$$

$(800\ \text{K} < T < 1200\ \text{K})$

$\dot{M}$ is the total mass flow rate and $\dot{N}_{\text{CH4}}$ is the molal flow rate of $CH_4$.

$$\dot{M} = \frac{\dot{M}_{\text{CH4}} \cdot \dot{M}\text{W}_{\text{in}} \cdot \Sigma\,\text{Mols}}{\dot{M}\text{W}_{\text{CH4}}} \quad \dot{N}_{\text{CH4}} = \frac{\dot{M}_{\text{CH4}}}{\dot{M}\text{W}_{\text{CH4}}}$$

$$\dot{M} = 54{,}174.5\ \frac{\text{kg}}{\text{h}} \quad \dot{N}_{\text{CH4}} = 155{,}860.3\ \frac{\text{mol}}{\text{h}}$$

*Overall refractory heat-transfer coefficient:*

$$D_r = 0.343\ \text{m} \quad k_r = 0.00050\ \frac{\text{kW}}{\text{m} \cdot \text{K}}$$

$$h_0 = 0.0114\ \frac{\text{kW}}{\text{m}^2 \cdot \text{K}} \quad h_0 = 2.0077\ \frac{\text{Btu}}{\text{h} \cdot \text{ft}^2 \cdot {}^\circ\text{R}} \quad h_1 = 0.0170\ \frac{\text{kW}}{\text{m}^2 \cdot \text{K}}$$

$$h_1 = 2.9939\ \frac{\text{Btu}}{\text{h} \cdot \text{ft}^2 \cdot \text{K}} \quad U = \frac{1}{\frac{1}{h_0} + \frac{1}{h_1} + \frac{D_r}{k_r}}$$

$$U = 0.001201\ \frac{\text{kW}}{\text{m}^2 \cdot \text{K}} \quad U = 0.2115\ \frac{\text{Btu}}{\text{h} \cdot \text{ft}^2 \cdot {}^\circ\text{R}}$$

*START OF ITERATION LOOP: Successive Substitution with $T_g$ as the Trial Variable*

Assume $T_g = 1{,}759.1633222447$ K $\quad T_e = T_g - \Delta T_{ge} \quad T_e = 1589.2$ K

$$E_g = \sigma \cdot T_g^4 \quad E_g = 543.05\ \frac{\text{kW}}{\text{m}^2}$$

*Compute temperature-dependent mean effective gas emissivity via linear interpolation:*

$\tau_m = \text{LINTF}(T_g, 0.37014, 0.418442) \quad a_m = \text{LINTF}(T_g, 0.44181, 0.38435)$

$\tau_m = 0.3934 \quad a_m = 0.4141 \quad \varepsilon_m = a_m(1 - \tau_m) \quad \varepsilon_m = 0.2512$

Compare interpolated value:

$\varepsilon_{\text{com}} = \text{LINTF}(T_g, 0.27828, 0.22352) \quad \varepsilon_{\text{com}} = 0.2519$

*Direct and total exchange areas for WSGG gray gas component:*

$$ss_2 = \tau_m \cdot ss_1 \quad sg_2 = (AI - ss_2) \begin{bmatrix} 1 \\ 1 \end{bmatrix} \quad R_2 = (AI - ss_2 \cdot \rho I)^{-1}$$

$$ss_2 = \begin{pmatrix} 26.91 & 17.94 \\ 17.94 & 11.96 \end{pmatrix} \text{m}^2 \quad sg_2 = \begin{pmatrix} 69.15 \\ 46.10 \end{pmatrix} \text{m}^2 \quad SS_2 = \varepsilon I \cdot AI \cdot R_2 \cdot ss_2 \cdot \varepsilon I$$

*Compute directed exchange areas:*

$$\text{DSS} = (1 - a_m) \cdot SS_1 + a_m \cdot SS_2 \quad \text{DSG} = a_m \cdot \varepsilon\text{I} \cdot AI \cdot R_2 \cdot sg_2$$

*Refractory augmented directed gas-sink exchange area:*

$$\text{DS1GR} = \text{DSG}_1 + \frac{\text{DSS}_{1,2} \cdot \text{DSG}_2}{\text{DSS}_{1,2} + \text{DSG}_2} \quad \text{DS1GR} = 35.59\ \text{m}^2 \quad \text{Eq. (5-172}a\text{)}$$

*Compute refractory temperature ($T_2$); assume radiative equilibrium:*

Equation (5-172*b*): $E_2 = \dfrac{\text{DSS}_{2,1} \cdot E_1 + \text{DSG}_2 \cdot E_g}{\text{DSS}_{2,1} + \text{DSG}_2}$

$$E_2 = 231.24\ \frac{\text{kW}}{\text{m}^2}$$

$$T_2 = \left(\frac{E_2}{\sigma}\right)^{0.25} \quad T_2 = 1421.1\ \text{K}$$

*Enthalpy balance: Basis:* 1 mol $CH_4$:

$$h_{\text{in}} = \text{LHV} + (\Sigma\,\text{Mol} - 1) \cdot \text{MC}p_{\text{air}} \cdot (T_{\text{air}} - T_0) \quad h_{\text{in}} = 240{,}219.9\ \frac{\text{cal}}{\text{mol}}$$

*Compute pseudoadiabatic flame temperature $T_f$:*

$$T_f = T_0 + \frac{h_{\text{in}}}{\Sigma\,\text{Mols}\ \text{MC}p(T_e)} \quad h_{\text{out}} = \Sigma\,\text{mols} \cdot \text{MC}p(T_e) \cdot (T_e - T_0)$$

$$T_f = 2580.5\ \text{K} \quad h_{\text{out}} = 135{,}880.8\ \frac{\text{cal}}{\text{mol}}$$

$$H_{\text{in}} = \dot{N}_{\text{CH4}} \cdot h_{\text{in}} \quad H_{\text{out}} = \dot{N}_{\text{CH4}} \cdot h_{\text{out}} \quad \Delta H = H_{\text{out}} - H_{\text{in}}$$

$$H_{\text{in}} = 43{,}543.59\ \text{kW} \quad H_{\text{out}} = 24{,}630.51\ \text{kW} \quad \Delta H = -18{,}913.08\ \text{kW}$$

*Overall enthalpy balance:*

$$Q_{1g} = \text{DS1GR} \cdot (E_g - E_1) \quad Q_{1g} = 17{,}308.45\ \text{kW}$$
$$Q_{1\text{con}} = h_1 \cdot A_1 \cdot (T_g - T_1) \quad Q_{1\text{con}} = 1471.26\ \text{kW}$$
$$Q_{2\text{con}} = U \cdot A_2 \cdot (T_g - T_0) \quad Q_{2\text{con}} = 133.37\ \text{kW}$$

$$\text{ERROR} = Q_{1g} + Q_{1\text{con}} + Q_{2\text{con}} + \Delta H \quad \%\text{ERROR1} = 100\ \frac{\text{ERROR}}{\Delta H}$$

$\text{ERROR} = -0.0000$ kW $\quad \%\text{ERROR1} = 0.00000$

$$T_{g\text{calc}} = \left[\frac{\text{DS1GR} \cdot E_1 - (\Delta H + Q_{1\text{Con}} + Q_{2\text{Con}})}{\text{DS1GR} \cdot \sigma}\right]^{0.25} \quad T_{g\,\text{calc}} = 1759.16332\ \text{K}$$

*Average assumed and calculated temperatures for next iteration:*

$$T_{g,\text{new}} = \frac{T_g + T_{g\text{calc}}}{2} \qquad T_{g\text{new}} = 1759.1633222935\ \text{K} \qquad \text{Go to Start}$$

*END OF ITERATION LOOP: Final Gas Temperature* $T_g = 1759.16$ K

$$\eta_g = \frac{H_{\text{in}} - H_{\text{out}}}{H_{\text{in}}} \text{ or } \eta_{1g} = \frac{T_f - T_e}{T_f - T_0} \qquad \eta_g = 0.43435 \qquad \eta_{1g} = 0.43435$$

*Heat flux density calculations:*

$$q_1 = \frac{Q_{1g} + Q_{1\text{Con}}}{A_1} \qquad q_{\text{tube}} = q_1 \cdot \left(2 \cdot \frac{D_{\text{tube}}}{2 \cdot \pi \cdot D_{\text{tube}}}\right)$$

$$q_1 = 164.7\ \frac{\text{kW}}{\text{m}^2} \qquad q_{\text{tube}} = 52.44\ \frac{\text{kW}}{\text{m}^2}$$

*Note:* This example was also solved with $\Delta T_{ge} = 0$. The results were as follows: $T_f = 2552.8$ K, $T_g = T_e = 1707.1$ K, $T_2 = 1381.1$ K, $\eta_g = 37.51$ percent, $D_{\text{eff}} = 0.53371$, and $\Delta H = 16{,}332.7$ kW. The WSCC model with $\Delta T_{ge} = 0$ predicts a lower performance bound.

*Compare dimensionless WSCC model:*

$$\Theta_0 = \frac{T_0}{T_f} \quad \Theta_1 = \frac{T_1}{T_f} \quad \Delta T_{\text{star}} = \frac{\Delta T_{\text{ge}}}{T_f}$$

$$T_{g1} = \frac{T_1 + T_g}{2}$$

$$\Theta_0 = 0.1155 \qquad \Theta_1 = 0.3875 \qquad \Delta T_{\text{star}} = 0.06588 \qquad T_{g1} = 1379.58\ \text{K}$$

$$C_{P,\text{Prod}} = \frac{MCp(T_e)}{MW_{\text{in}}} \qquad C_{P,\text{Prod}} = 0.000352\ \text{kW} \cdot \frac{\text{h}}{\text{kg} \cdot \text{K}}$$

$$N_{\text{FD}} = \dot{M} \frac{C_{P,\text{Prod}}}{\sigma \cdot T_f^3 \cdot A_1} \qquad N_{\text{CR}} \frac{h_1}{4 \cdot \sigma \cdot T_{g1}^3} \qquad N_{\text{eff}} \frac{N_{\text{FD}}}{\frac{\text{DS1GR}}{A_1} + N_{\text{CR}}}$$

$$N_{\text{FD}} = 0.17176 \qquad N_{\text{CR}} = 0.02855 \qquad D_{\text{eff}} = 0.50409 \qquad \frac{\text{DS1GR}}{A_1} = 0.31218$$

$$\eta' = \eta_g \cdot (1 - \Theta_0) \qquad D_{1\,\text{eff}} = \frac{(1 + \Delta T_{\text{star}} - \eta_{\text{prime}})^4 - \Theta_1^4}{\eta_{\text{prime}}}$$

$$D_{1\,\text{eff}} = 0.50350 \qquad \text{versus} \qquad D_{\text{eff}} = 0.50409$$

This small discrepancy is due to linearization and neglect of convective refractory heat losses in the dimensionless WSCC model.

*Compare dimensionless LPFF model:*

$$R_{\text{in}} = \frac{1}{\Theta_1} \qquad R_{\text{in}} = 2.58050$$

*Trial-and-error calculation to match effective firing densities:*
Assume

$$T_{\text{out}} = 1000.13763\ \text{K} \qquad R_{\text{out}} = \frac{T_{\text{out}}}{T_1} \qquad R_{\text{out}} = 1.00014 \qquad \frac{4}{D_{\text{eff}}} = 7.93513$$

$$\text{CLong} = -\ln\left[\frac{(R_{\text{out}} - 1) \cdot (R_{\text{in}} + 1)}{(R_{\text{in}} - 1) \cdot (R_{\text{out}} + 1)}\right] - 2 \cdot \text{atan}\left(\frac{R_{\text{in}} - R_{\text{out}}}{1 + R_{\text{in}} \cdot R_{\text{out}}}\right) \quad \text{CLong} = 7.93514$$

$$\eta L_f = \frac{R_{\text{in}} - R_{\text{out}}}{R_{\text{in}} - 1} \quad \eta L_f = 0.99991292 \quad \text{versus} \quad \eta_g = 0.43435$$

*Note*: The long plug flow furnace model is so efficient that it would be grossly underfired using the computed WSCC effective firing density. Of the two models, the LPFF model always predicts an upper theoretical performance limit. (This example was developed as a MATHCAD 15 worksheet. MATHCAD is registered trademark of Parametric Technology Corporation.)

**WSCC Model Utility and More Complex Zoning Models** Despite its simplicity, the WSCC construct has a wide variety of practical uses and is of significant pedagogical value. Here an engineering situation of inordinate complexity is described by the definition of only eight dimensionless quantities $D_{\text{eff}}$, $N_{\text{FD}}$, $\overline{S_1 G}_R / A_1$, $N_{\text{CR}}$, $\eta_g$, $\Delta^*$, $\Theta_0$, and $\Theta_1$. The first three are related by the simple algebraic definition $D_{\text{eff}} = N_{\text{FD}} / (\overline{S_1 G}_R / A_1 + N_{\text{CR}})$. These dimensionless quantities contain all the physical input information for the model, namely, furnace parameters and geometry, radiative properties of the combustion products, and the stoichiometry and thermodynamics of the combustion process. The WSCC model leads to a dimensionless two-dimensional plot of *reduced* effective furnace efficiency versus dimensionless effective firing density (Fig. 5-21), which is characterized by only two additional parameters, namely, $\Delta^*$ and $\Theta_1$.

Of the models presented here, the WSCC model with $\Delta T_{ge} = 0$ produces the lowest furnace efficiencies. The long furnace model usually produces the highest furnace efficiency. This is really not a fair statement because two distinctly different pieces of process equipment are compared. In this regard, a more appropriate definition of the dimensionless firing density for the LPFF model might be $N'_{\text{FD}} = \dot{m} \overline{C}_p / \left(\sigma \cdot T_{g,\text{in}}^3 \cdot A_1\right)$. It may be counterintuitive, but the WSCC and LPFF models *generally do not* characterize the extreme conditions for the performance of combustors as in the case of chemical reactors.

Figure 5-21 has been used to correlate furnace performance data for a multitude of industrial furnaces and combustors. Typical operational domains for a variety of fuel-fired industrial furnaces are summarized in Table 5-8. The WSCC approach (or "speckled" furnace model) is a classic contribution to furnace design methodology which was first due to Hottel [Hottel, H. C., and A. F. Sarofim, *Radiative Transfer*, McGraw-Hill, New York, 1967]. The WSCC model provides a simple *furnace design template* which leads to a host of more complex furnace models. These models include an obvious extension to a tanks-in-series model as well as multizone models utilizing empirical cold-flow velocity patterns. For more information on practical furnace design models, see Hottel and Sarofim (*Radiative Transfer,* McGraw-Hill, New York, 1967, chap. 14). Qualitative aspects of process equipment have been treated in some detail elsewhere (Baukal, C. E., ed., *The John Zink Combustion Handbook,* CRC Press, Boca Raton, Fla., 2001).

**TABLE 5-8 Operational Domains for Representative Process Furnaces and Combustors**

| Domain | Furnace or combustor type | Dimensionless sink temperature | Dimensionless firing density |
|---|---|---|---|
| A | Oil processing furnaces; radiant section of oil tube stills and cracking coils | $\Theta_1 \approx 0.4$ | $0.1 < D_{\text{eff}} < 1.0$ |
| B | Domestic boiler combustion chambers | $\Theta_1 \approx 0.2$ | $0.5 < D_{\text{eff}} < 1.1$ |
| C | Glass furnaces | $0.7 < \Theta_1 < 0.8$ | $0.035 < D_{\text{eff}} < 0.8$ |
| D | Soaking pits | $\Theta_1 \approx 0.6$ | $0.7 < D_{\text{eff}} < 1.1$ |
| E | Gas-turbine combustors | $0.4 < \Theta_1 < 0.7$ | $4.0 < D_{\text{eff}} < 25.0$ |

## INTRODUCTION

This part of Sec. 5 provides a concise guide to solving problems in situations commonly encountered by chemical engineers. It deals with diffusivity and mass-transfer coefficient estimation and common flux equations, although material balances are also presented in typical coordinate systems to permit a wide range of problems to be formulated and solved.

Mass-transfer calculations involve transport properties, such as diffusivities, and other empirical factors that have been found to relate mass-transfer rates to measured "driving forces" in myriad geometries and conditions. The context of the problem dictates whether the fundamental or more applied coefficient should be used. One key distinction is that whenever there is flow parallel to an interface through which mass transfer occurs, the relevant coefficient is an empirical combination of properties and conditions. Conversely, when diffusion occurs in stagnant media or in creeping flow without transverse velocity gradients, ordinary diffusivities may be suitable for solving the problem. In either case, it is strongly suggested to employ data, whenever available, instead of relying on correlations.

Units employed in diffusivity correlations commonly followed the cgs system. Similarly, correlations for mass-transfer correlations used the cgs or English system. In both cases, only the most recent correlations employ SI units. Since most correlations involve other properties and physical parameters, often with mixed units, they are repeated here as originally stated. Common conversion factors are listed in Table 1-4.

**Fick's First Law** This equation (which, as noted, is frequently called Fick's first law, though to call it a law is a misnomer) relates flux of a component to its composition gradient, employing a constant of proportionality called *diffusivity.* It is reasonably accurate for binary mixtures in which the diffusing component ($A$) is dilute and when no conveyance (explained below) exists; hence, its applicability is very limited. It can be written in several forms, depending on the units and frame of reference. Three that are related but not identical are

$$ {}_{V}J_A = -D_{AB}\frac{dc_A}{dz} \approx {}_{M}J_A = -cD_{AB}\frac{dx_A}{dz} \propto {}_{m}J_A = -\rho D_{AB}\frac{dw_A}{dz} \qquad (5\text{-}189) $$

The first equality (on the left-hand side) corresponds to the molar flux with respect to the volume average velocity, while the equality in the center represents the molar flux with respect to the molar average velocity and the one on the right is the mass flux with respect to the mass average velocity. These fluxes must be used with consistent flux expressions for fixed coordinates and for $N_C$ components, such as

$$ N_A = {}_{V}J_A + c_A\sum_{i=1}^{N_C} N_i\bar{V}_i = {}_{M}J_A + x_A\sum_{i=1}^{N_C} N_i = \frac{{}_{m}J_A + w_A\sum_{i=1}^{N_C} n_i}{M_A} \qquad (5\text{-}190) $$

The summations account for *conveyance,* which is the amount of component $A$ carried by the net flow in the direction of diffusion. Those terms may account for as much as 10 percent of the flux, though in most cases it is much less, and it is frequently ignored. Some people refer to this as the "convective" term, but that usage conflicts with the other sense of convection which is promoted by flow perpendicular to the direction of flux.

**Mutual Diffusivity, Mass Diffusivity, and Interdiffusion Coefficient** Diffusivity is denoted by $D_{AB}$ and is defined by Fick's first law as the ratio of the flux to the concentration gradient, as in Eq. (5-189). It is analogous to the thermal diffusivity in Fourier's law and to the kinematic viscosity in Newton's law. These analogies are flawed because both heat and momentum are conveniently defined with respect to fixed coordinates, irrespective of the direction of transfer or its magnitude, while mass diffusivity most commonly requires information about bulk motion of the medium in which diffusion occurs. For liquids, $D_{AB}$ usually depends on the concentration of $A$ and only becomes constant as the concentration of $A$ approaches zero, where $D_{AB} = D^{\circ}_{AB}$, the infinite dilution limit diffusivity.

When the flux expressions are consistent, as in Eq. (5-190), the diffusivities in Eq. (5-189) are identical. As a result, experimental diffusivities are often measured under constant-volume conditions but may be used for applications involving open systems. It turns out that the two versions are very nearly equivalent for gas systems because there is negligible volume change on mixing. That is not usually true for liquids, however.

**Self-Diffusivity and Tracer Diffusivity** *Self-diffusivity* is denoted by $D_{A'A}$ and is the measure of mobility of a species in itself. For instance, $A'$ may represent a small concentration of molecules tagged with a radioactive isotope so they can be detected, but they do not have significantly different properties. Hence, the solution is ideal, and there are practically no gradients to "force" or "drive" diffusion. This kind of diffusion is presumed to be purely stochastic in nature. To cite a specific example, when $A$ is less mobile than $B$, their self-diffusion coefficients can be used as rough lower and upper bounds of the mutual diffusion coefficient; that is, $D_{A'A} \le D_{AB} \le D_{B'B}$. Obviously, when $A$ is more mobile than $B$, the inequalities are reversed. Similarly, *tracer diffusivity,* denoted by $D_{A'B}$, is related to both mutual and self-diffusivity. It is evaluated in the presence of a second component $B$, again using a tagged isotope of the first component. In the dilute range, tagging $A$ merely provides a convenient method for indirect composition analysis. Tracer diffusivities approach mutual diffusivities at the dilute limit, and they approach self-diffusivities at the pure component limit. That is, at the limit of dilute $A$ in $B$, $D_{A'B} \to D^{\circ}_{AB}$ and $D_{B'A} \to D_{B'B}$; likewise at the limit of dilute $B$ in $A$, $D_{B'A} \to D^{\circ}_{BA}$ and $D_{A'B} \to D_{A'A}$.

The tracer diffusivity and the self-diffusivity provide a means to understand ordinary diffusion and as order-of-magnitude estimates of mutual diffusivities. Darken's equation [Eq. (5-222)] was derived for tracer diffusivities but is often used to relate mutual diffusivities at moderate concentrations as opposed to infinite dilution. Zhu et al. [*Chem. Eng. Sci.* **132:** 250 (2015)] recently published a model for the prediction of mutual diffusion coefficients in binary liquid mixtures from tracer diffusion coefficients. Data and correlations for self-diffusivity and tracer diffusivity are covered later in this section.

**Mass-Transfer Coefficient** Denoted by $k_c$, $k_x$, $K_x$, and so on, the mass-transfer coefficient is the ratio of the flux to a concentration (or composition) difference. These coefficients generally represent rates of transfer that are much greater than those that occur by diffusion alone, as a result of convection or turbulence at the interface where mass transfer occurs. There exist several principles that relate that coefficient to the diffusivity and other fluid properties and to the intensity of motion and geometry. Examples that are outlined later are the film theory, the surface renewal theory, and the penetration theory, all of which pertain to idealized cases. For many situations of practical interest such as investigating the flow inside tubes and over flat surfaces as well as measuring external flow through banks of tubes, in fixed beds of particles, and the like, correlations have been developed that follow the same forms as the above theories. Examples of these are provided in the tables of mass-transfer coefficient correlations.

**Problem-Solving Methods** Most, if not all, problems or applications that involve mass transfer can be approached by a systematic course of action. In the simplest cases, the unknown quantities are obvious. In more complex (e.g., multicomponent, multiphase, multidimensional, nonisothermal, and/or transient) systems, it is more subtle to resolve the known and unknown quantities. For example, in multicomponent systems, one must know the fluxes of the components before predicting their effective diffusivities and vice versa. More will be said about that dilemma later. Once the known and unknown quantities are resolved, however, a combination of conservation equations, definitions, empirical relations, and properties is applied to arrive at an answer. Figure 5-22 is a flowchart that illustrates the primary types of information and their relationships, and it applies to many mass-transfer problems.

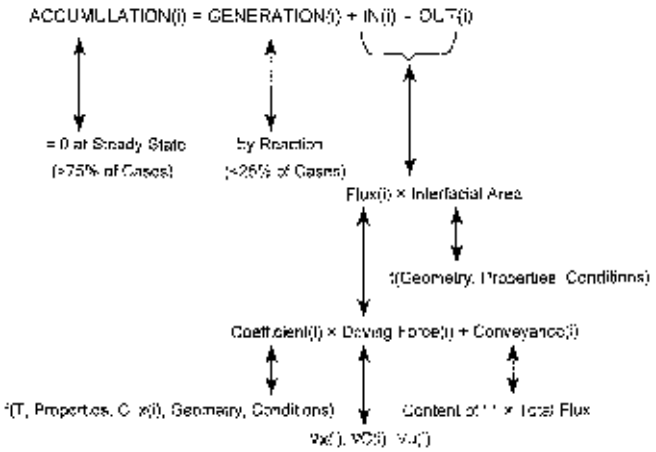

**FIG. 5-22** Flowchart illustrating problem-solving approach using mass-transfer rate expressions in the context of mass conservation.

### Nomenclature and Units—Mass Transfer

| Symbols | Definition | SI units | U.S. Customary System (USCS) units |
|---|---|---|---|
| $a$, $a_p$ | Effective interfacial mass-transfer area per unit volume | $m^2/m^3$ | $ft^2/ft^3$ |
| $A_{cs}$ | Cross-sectional area of vessel | $m^2$ or $cm^2$ | $ft^2$ |
| $A'$ | Constant (see Table 5-23K) | | |
| $C$ | Concentration = $P/RT$ for ideal gas | $mol/m^3$, mol/L, or gequiv/L | $lbmol/ft^3$ |
| $c_i$ | Concentration of component $i = x_i c$ at gas-liquid interface | $mol/m^3$, mol/L, or gequiv/L | $lbmol/ft^3$ |
| $c_P$ | Specific heat | $kJ/(kg \cdot K)$ | $Btu/(lb \cdot °F)$ |
| $d$ | Characteristic length | m or cm | ft |
| $d_b$ | Bubble diameter | m | ft |
| $d_c$ | Column diameter | m or cm | ft |
| $d_{drop}$ | Sauter mean diameter | m | ft |
| $d_{imp}$ | Impeller diameter | m | ft |
| $d_{pore}$ | Pore diameter | m, cm, or μm | ft |
| $D_{A,A}$ | Self-diffusivity (= $D_A$ at $x_A = 1$) | $m^2/s$ or $cm^2/s$ | $ft^2/h$ |
| $D_{AB}$ | Mutual diffusivity | $m^2/s$ or $cm^2/s$ | $ft^2/h$ |
| $D^{\circ}_{AB}$ | Mutual diffusivity at infinite dilution of $A$ in $B$ | $m^2/s$ or $cm^2/s$ | $ft^2/h$ |
| $D_{eff}$ | Effective diffusivity within a porous solid = $\varepsilon_p D/\tau$ | $m^2/s$ | $ft^2/h$ |
| $D_K$ | Knudson diffusivity for gases in small pores | $m^2/s$ or $cm^2/s$ | $ft^2/h$ |
| $D_L$ | Liquid-phase diffusion coefficient | $m^2/s$ | $ft^2/h$ |
| $D_S$ | Surface diffusivity | $m^2/s$ or $cm^2/s$ | $ft^2/h$ |
| $D_{AB}$ | Maxwell-Stefan mutual diffusivity | $m^2/s$ or $cm^2/s$ | $ft^2/h$ |
| $E$ | Energy dissipation rate/mass | $L^2/t^3$ | W/kg or HP/lb |
| $E_S$ | Activation energy for surface diffusion | J/mol or cal/mol | |
| $f$ | Friction factor for fluid flow | Dimensionless | Dimensionless |
| $F$ | Faraday's constant | 96,487 C/eq | |
| $g$ | Acceleration due to gravity | $m/s^2$ | $ft/h^2$ |
| $g_c$ | Conversion factor | 1.0 | $4.17 \times 10^8$ lb · ft/(lbf · $h^2$) |
| $G$ | Gas-phase mass flux | $kg/(s \cdot m^2)$ | $lb/(h \cdot ft^2)$ |
| $G_a$ | Dry air flux | $kg/(s \cdot m^2)$ | $lb/(h \cdot ft^2)$ |
| $G_M$ | Molar gas-phase mass flux | $kmol/(s \cdot m^2)$ | $lbmol/(h \cdot ft^2)$ |
| $h'$ | Heat-transfer coefficient | $W/(m^2 \cdot K) = J/(s \cdot m^2 \cdot K)$ | $Btu/(h \cdot ft^2 \cdot °F)$ |
| $h_T$ | Total height of tower packing | m | ft |
| $H$ | Compartment height | m | ft |
| $H$ | Henry's law constant | kPa/(mole-fraction solute in liquid phase) | $(lbf/in^2)$/(mole-fraction solute in liquid phase) |
| $H'$ | Henry's law constant | kPa/[kmol/($m^3$ solute in liquid phase)] | $(lbf/in^2)$/(lbmol/$ft^3$ solute in liquid phase) or atm/[lbmol/($ft^3$ solute in liquid phase)] |
| $H_G$ | Height of 1 transfer unit based on gas-phase resistance | m | ft |
| $H_{OG}$ | Height of 1 overall gas-phase mass-transfer unit | m | ft |
| $H_L$ | Height of 1 transfer unit based on liquid-phase resistance | m | ft |
| $H_{OL}$ | Height of 1 overall liquid-phase mass-transfer unit | m | ft |
| HTU | Height of 1 transfer unit (general) | m | ft |
| $j_D$, $j_M$ | Chilton-Colburn factor for mass transfer, Eq. (5-313) | Dimensionless | Dimensionless |
| $j_H$ | Chilton-Colburn factor for heat transfer | Dimensionless | Dimensionless |
| ${}_m J_A$ | Mass flux of $A$ by diffusion with respect to mean mass velocity | $kmol/(m^2 \cdot s)$ or $mol/(cm^2 \cdot s)$ | $lbmol/(ft^2 \cdot h)$ |
| ${}_M J_A$ | Molar flux of $A$ by diffusion with respect to mean molar velocity | $kmol/(m^2 \cdot s)$ or $mol/(cm^2 \cdot s)$ | $lbmol/(ft^2 \cdot h)$ |
| ${}_v J_A$ | Molar flux of $A$ with respect to mean volume velocity | $kmol/(m^2 \cdot s)$ | $lbmol/(ft^2 \cdot h)$ |
| $J_{Si}$ | Molar flux by surface diffusion | $kmol/(m^2 \cdot s)$ or $gmol/(cm^2 \cdot s)$ | $lbmol/(ft^2 \cdot h)$ |
| $k$ | Boltzmann's constant | $8.9308 \times 10^{-10}$ gequiv Ω/s | |
| $k$ | Film mass-transfer coefficient | m/s or cm/s | ft/h |
| $k$ | Thermal conductivity | $(J \cdot m)/(s \cdot m^2 \cdot K)$ | $Btu/(h \cdot ft \cdot °F)$ |
| $k'$ | Mass-transfer coefficient for dilute systems | $kmol/[(s \cdot m^2)(kmol/m^3)]$ or m/s | $lbmol/[(h \cdot ft^2) \times (lbmol/ft^3)]$ or ft/h |
| $k_G$ | Gas-phase mass-transfer coefficient dilute systems | $kmol/[(s \cdot m^2)$(kPa solute partial pressure)] | $lbmol/[(h \cdot ft^2)lbf/in^2$ solute partial pressure)] |
| $k'_G$ | Gas-phase mass-transfer coefficient dilute systems | $kmol/[(s \cdot m^2)$(mole fraction in gas)] | $lbmol/[(h \cdot ft^2)$(mole fraction in gas)] |
| $k_G a$ | Volumetric gas-phase mass transfer | $kmol/[(s \cdot m^3)$(mole fraction)] | $(lbmol)/[(h \cdot ft^3) \times$ (mole fraction)] |
| $\hat{k}_G a$ | Overall volumetric gas-phase mass-transfer coefficient concentrated systems | $kmol/(s \cdot m^3)$ | $lbmol/(h \cdot ft^3)$ |
| $\hat{k}^o_L$ | Liquid-phase mass-transfer coefficient for pure absorption (no reaction) | $kmol/(s \cdot m^2)$ | $lbmol/(h \cdot ft^2)$ |
| $k_L$ | Liquid-phase mass-transfer coefficient dilute systems | $kmol/[(s \cdot m^2)$(mole-fraction solution in liquid)] | $(lbmol)/[(h \cdot ft^2) \times$ (mole-fraction solute in liquid)] |
| $k'_L$ | Liquid-phase mass-transfer coefficient dilute systems | $kmol/[(s \cdot m^2) \times (kmol/m^3)]$ or m/s | $(lbmol)/[(h \cdot ft^2) \times (lbmol/ft^3)]$ or ft/h |
| $\hat{k}_L$ | Liquid-phase mass-transfer coefficient concentrated systems | $kmol/(s \cdot m^2)$ | $lbmol/(h \cdot ft^2)$ |
| $k_L a$ | Volumetric liquid-phase mass-transfer coefficient dilute systems | $kmol/[(s \cdot m^3) \times$ (mole fraction)] | $lbmol/[(h \cdot ft^3) \times$ (mole fraction)] |
| $K$ | Overall mass-transfer coefficient | m/s or cm/s | ft/h |
| $K$ | $\alpha/R$ = specific conductance | S/m | |
| $K_G$ | Overall gas-phase mass-transfer coefficient dilute systems | $kmol/[(s \cdot m^2)$(mole fraction)] | $(lbmol)/[(h \cdot ft^2) \times$ (mole fraction)] |
| $\hat{K}_G$ | Overall gas-phase mass-transfer coefficient concentrated systems | $kmol/(s \cdot m^2)$ | $lbmol/(h \cdot ft^2)$ |
| $K_G a$ | Overall volumetric gas-phase mass-transfer dilute systems | $kmol/[(s \cdot m^3) \times$ (mole-fraction solute in gas)] | $lbmol/[(h \cdot ft^3$(mole-fraction solute in gas)] |
| $K'_G a$ | Overall volumetric gas-phase mass-transfer dilute systems | $kmol/[(s \cdot m^3)$(kPa solute partial pressure)] | $lbmol/[(h \cdot ft^3) \times (lbf/in^2$ solute partial pressure)] |

**Nomenclature and Units—Mass Transfer** (*Continued*)

| Symbols | Definition | SI units | U.S. Customary System (USCS) units |
|---|---|---|---|
| $(Ka)_H$ | Overall enthalpy mass-transfer coefficient | kmol/[(s · m²)(mole fraction)] | lb/[(h · ft³)(lb water/lb dry air)] |
| $K_L$ | Overall liquid-phase mass-transfer coefficient | kmol/[(s · m²)(mole fraction)] | lbmol/[(h · ft²)(mole fraction)] |
| $\hat{K}_L$ | Liquid-phase mass-transfer coefficient concentrated systems | kmol/(s · m²) | lbmol/(h · ft²) |
| $K_La$ | Overall volumetric liquid-phase mass-transfer coefficient dilute systems | kmol/[(s · m³)(mole-fraction solute in liquid)] | lbmol/[(h · ft³)(mole-fraction solute in liquid)] |
| $\hat{K}_La$ | Overall volumetric liquid-phase mass-transfer coefficient concentrated systems | kmol/(s · m³) | lbmol/(h · ft³) |
| l | Mean free path, Eq. (5-261) | m | ft |
| $L$ | Liquid-phase mass flux | kg/(s · m²) | lb/(h · ft²) |
| $L_M$ | Molar liquid-phase mass flux | kmol/(s · m²) | lbmol/(h · ft²) |
| $m$ | Slope of equilibrium curve = $dy/dx$ (mole-fraction solute in gas)/(mole-fraction solute in liquid) | Dimensionless | Dimensionless |
| $m$ | Molality of solute | mol/1000 g solvent | |
| $M_i$ | Molecular weight of species $i$ | kg/kmol or g/mol | lb/lbmol |
| $M$ | Mass in a control volume $V$ | kg or g | lb |
| $\lvert n_+\rvert\lvert n_-\rvert$ | Valences of cationic and anionic species | Dimensionless | Dimensionless |
| $n'$ | See Table 5-23K | Dimensionless | Dimensionless |
| $n_A$ | Mass flux of $A$ with respect to fixed coordinates | kg/(s · m²) | lb/(h · ft²) |
| $N$ | Impeller speed | r/s | r/min |
| $N'$ | Number of deck levels | Dimensionless | Dimensionless |
| $N_A$ | Interphase mass-transfer rate of solute $A$ per interfacial area with respect to fixed coordinates | kmol/(s · m²) | lbmol/(h · ft²) |
| $N_c$ | Number of components | Dimensionless | Dimensionless |
| $N_{Fr}$ | Froude number ($d_{imp}N^2/g$) | Dimensionless | Dimensionless |
| $N_{Gr}$ | Grashof number $\dfrac{gx^3}{(\mu/\rho)^2}\left(\dfrac{\rho_\infty}{\rho_o}-1\right)$ | Dimensionless | Dimensionless |
| $N_{OG}$ | Number of overall gas-phase mass-transfer units | Dimensionless | Dimensionless |
| $N_{OL}$ | Number of overall liquid-phase mass-transfer units | Dimensionless | Dimensionless |
| NTU | Number of transfer units (general) | Dimensionless | Dimensionless |
| $N_{Kn}$ | Knudson number = $l/d_{pore}$ | Dimensionless | Dimensionless |
| $N_{Pr}$ | Prandtl number ($c_p\mu/k$) | Dimensionless | Dimensionless |
| $N_{Re}$ | Reynolds number ($Gd/\mu_G$) | Dimensionless | Dimensionless |
| $N_{Sc}$ | Schmidt number ($\mu_G/\rho_G D_{AB}$) or ($\mu_L/\rho_L D_L$) | Dimensionless | Dimensionless |
| $N_{Sh}$ | Sherwood number ($\hat{k}_G RTd/D_{AB}p_T$), see also Tables 5-16 to 5-23 | Dimensionless | Dimensionless |
| $N_{St}$ | Stanton number $\hat{k}_G/G_M$ or $\hat{k}_L/L_M$ | Dimensionless | Dimensionless |
| $N_{We}$ | Weber number ($\rho_c N^2 d^3_{imp}/\sigma$) | Dimensionless | Dimensionless |
| $p$ | Solute partial pressure in bulk gas | kPa | lbf/in² |
| $p_{BM}$ | Log mean partial pressure difference of stagnant gas $B$ | Dimensionless | Dimensionless |
| $p_i$ | Solute partial pressure at gas-liquid interface | kPa | lbf/in² |
| $p_T$ | Total system pressure | kPa | lbf/in² |
| $P$ | Pressure | Pa | lbf/in² or atm |
| $P$ | Power | W | |
| $P_c$ | Critical pressure | Pa | lbf/in² or atm |
| Per | Perimeter/area | m⁻¹ | ft⁻¹ |
| $Q$ | Volumetric flow rate | m³/s | ft³/h |
| $r_A$ | Radius of dilute spherical solute | Å | |
| $R$ | Gas constant | 8.314 J/(mol $K$) = 8.314 Pa · m³/(mol $K$) = 82.057 atm · cm³/(mol $K$) | 10.73 (ft³ · psia)/(lbmol · h) |
| $\boldsymbol{R}$ | Solution electrical resistance | Ω | Ω |
| $R_i$ | Radius of gyration of the component $i$ molecule | Å | |
| $s$ | Fractional surface-renewal rate | s⁻¹ | h⁻¹ |
| $S$ | Tower cross-sectional area = $\pi d^2/4$ | m² | ft² |
| $t$ | Contact time | s | h |
| $t_f$ | Formation time of drop | s | h |
| $T$ | Temperature | K | °R |
| $T_b$ | Normal boiling point | K | °R |
| $T_c$ | Critical temperature | K | °R |
| $T_r$ | Reduced temperature = $T/T_c$ | Dimensionless | Dimensionless |
| $u$, $\upsilon$ | Fluid velocity | m/s or cm/s | ft/h |
| $u_\infty$ | Velocity away from object | m/s | ft/h |
| $u_L$ | Superficial liquid velocity in vertical direction | m/s | ft/h |
| $\upsilon_s$ | Slip velocity | m/s | ft/h |
| $\upsilon_T$ | Terminal velocity | m/s | ft/h |
| $\upsilon_{TS}$ | Stokes law terminal velocity | m/s | ft/h |
| $V$ | Packed volume in tower | m³ | ft³ |
| $V$ | Control volume | m³ or cm³ | ft³ |
| $V_b$ | Volume at normal boiling point | m³/kmol or cm³/mol | ft³/lbmol |
| $V_i$ | Molar volume of $i$ at its normal boiling point | m³/kmol or cm³/mol | ft³/lbmol |

| Symbols | Definition | SI units | U.S. Customary System (USCS) units |
|---|---|---|---|
| $\overline{v}_i$ | Partial molar volume of $i$ | $m^3$/kmol or $cm^3$/mol | $ft^3$/lbmol |
| $V_{mi}^{\ell}$ | Molar volume of the liquid-phase component $i$ at melting point | $m^3$/kmol or $cm^3$/mol | $ft^3$/lbmol |
| $V_{\text{tower}}$ | Tower volume per area | $m^3/m^2$ | $ft^3/ft^2$ |
| $w$ | Width of film | m | ft |
| $x$ | Length along plate | m | ft |
| $x$ | Mole-fraction solute in bulk-liquid phase | (kmol solute)/(kmol liquid) | (lbmol solute)/(lbmol liquid) |
| $x_A$ | Mole fraction of component $A$ | kmol $A$/kmol fluid | lbmol $A$/lbmol fluid |
| $x^o$ | Mole-fraction solute in bulk liquid in equilibrium with bulk-gas solute concentration $y$ | (kmol solute)/(kmol liquid) | (lbmol solute)/(lbmol liquid) |
| $x_{BM}$ | Logarithmic-mean solvent concentration between bulk liquid and interface values | (kmol solvent)/(kmol liquid) | (lbmol solvent)/(lbmol liquid) |
| $x^o_{BM}$ | Logarithmic-mean inert-solvent concentration between bulk-liquid value and value in equilibrium with bulk gas | (kmol solvent)/(kmol liquid) | (lbmol solvent)/(lbmol liquid) |
| $x_i$ | Mole-fraction solute in liquid at gas-liquid interface | (kmol solute)/(kmol liquid) | (lbmol solute)/(lbmol liquid) |
| $y$ | Mole-fraction solute in bulk-gas phase | (kmol solute)/(kmol gas) | (lbmol solute)/(lbmol gas) |
| $y_{BM}$ | Logarithmic-mean inert-gas concentration [Eq. (5-274$a$)] | (kmol inert gas)/(kmol gas) | (lbmol inert gas)/(lbmol gas) |
| $y^o_{BM}$ | Logarithmic-mean inert-gas concentration | (kmol inert gas)/(kmol gas) | (lbmol inert gas)/(lbmol gas) |
| $y_i$ | Mole fraction solute in gas at interface | (kmole solute)/(kmol gas) | (lbmol solute)/(lbmol gas) |
| $y_i^o$ | Mole-fraction solute in gas at interface in equilibrium with liquid-phase interfacial solute concentration $x_i$ | (kmol solute)/(kmol gas) | (lbmol solute)/(lbmol gas) |
| $z$ | Direction of unidimensional diffusion | m | ft |
| | Greek symbols | | |
| $\alpha$ | $1 + N_B/N_A$ | Dimensionless | Dimensionless |
| $\alpha$ | Conductance cell constant (measured) | $cm^{-1}$ | |
| $\beta$ | $M_A^{1/2} P_c^{1/3}/T_c^{5/6}$ | Dimensionless | Dimensionless |
| $\delta$ | Effective thickness of stagnant-film layer | m | ft |
| $\varepsilon$ | Fraction of discontinuous phase in continuous phase for two-phase flow | Dimensionless | Dimensionless |
| $\varepsilon$ | Void fraction available for gas flow or fractional gas holdup | $m^3/m^3$ | $ft^3/ft^3$ |
| $\varepsilon_A$ | Characteristic Lennard-Jones energy | Dimensionless | Dimensionless |
| $\varepsilon_{AB}$ | $(\varepsilon_A\varepsilon_B)^{1/2}$ | Dimensionless | Dimensionless |
| $\gamma_i$ | Activity coefficient of solute $i$ | Dimensionless | Dimensionless |
| $\gamma_\pm$ | Solute mean ionic activity coefficient | Dimensionless | Dimensionless |
| $\lambda_+$, $\lambda_-$ | Infinite dilution conductance of cation and anion | $cm^2/(\text{gequiv}\cdot\Omega)$ | |
| $\Lambda$ | $1000\ \text{K}/C = \lambda_+ + \lambda_- = \Lambda_o + f(C)$ | $cm^2/\Omega$ gequiv | |
| $\Lambda_o$ | Infinite dilution conductance | $cm^2$/gequiv $\Omega$ | |
| $\mu_i$ | Dipole moment of $i$ | Debeyes | |
| $\mu_i$ | Viscosity of pure $i$ | cP or Pa s | lb/(h·ft) |
| $\mu_G$ | Gas-phase viscosity | kg/(s·m) | lb/(h·ft) |
| $\mu_L$ | Liquid-phase viscosity | kg/(s·m) | lb/(h·ft) |
| $\nu$ | Kinematic viscosity = $\rho/\mu$ | $m^2/s$ | $ft^2/h$ |
| $\rho$ | Density of $A$ | $kg/m^3$ or $g/cm^3$ | $lb/ft^3$ |
| $\rho_c$ | Critical density of $A$ | $kg/m^3$ or $g/cm^3$ | $lb/ft^3$ |
| $\rho_c$ | Density continuous phase | $kg/m^3$ | $lb/ft^3$ |
| $\rho_G$ | Gas-phase density | $kg/m^3$ | $lb/ft^3$ |
| $\overline{\rho}_L$ | Average molar density of liquid phase | $kmol/m^3$ | $lbmol/ft^3$ |
| $\rho_p$ | Particle density | $kg/m^3$ or $g/cm^3$ | $lb/ft^3$ |
| $\rho_r$ | Reduced density = $\rho/\rho_c$ | Dimensionless | Dimensionless |
| $\psi_i$ | Parachor of component $i = V_i\sigma^{1/4}$ | | |
| $\psi$ | Parameter, Table 5-23G | Dimensionless | Dimensionless |

## CONTINUITY AND FLUX EXPRESSIONS

**Material Balances** Whenever mass-transfer applications involve equipment of specific dimensions, flux equations alone are inadequate to assess results. A material balance or continuity equation must also be used. When the geometry is simple, macroscopic balances suffice. The following equation is an overall mass balance for a unit having $N_m$ bulk-flow ports and $N_n$ ports or interfaces through which diffusive flux can occur:

$$\frac{dM}{dt} = \sum_{i=1}^{N_m} m_i + \sum_{i=1}^{N_n} n_i A_{cs_i} \tag{5-191}$$

where $M$ represents the mass in the unit volume $V$ at any time $t$; $m_i$ is the mass flow rate through the $i$th port; and $n_i$ is the mass flux through the $i$th port, which has a cross-sectional area of $A_{csi}$. The corresponding balance equation for individual components includes a reaction term:

$$\frac{dM_j}{dt} = \sum_{i=1}^{N_m} m_{ij} + \sum_{i=1}^{N_n} n_{ij} A_{cs_i} + r_j V \tag{5-192}$$

For the $j$th component, $m_{ij} = m_i w_{ij}$ is the component mass flow rate in stream $i$; $w_{ij}$ is the mass fraction of component $j$ in stream $i$; and $r_j$ is the net reaction rate (mass generation minus consumption) per unit volume $V$ that contains mass $M$. If it is inconvenient to measure mass flow rates, the product of density and the volumetric flow rate is used instead.

In addition, most situations that involve mass transfer require material balances, but the pertinent area is ambiguous. Examples are packed columns for absorption, distillation, or extraction. In such cases, flow rates through the discrete ports (nozzles) must be related to the mass-transfer rate in the packing. As a result, the mass-transfer rate is determined via flux equations, and the overall material balance incorporates the stream flow rates $m_i$ and integrated fluxes. In such instances, it is common to begin with the most general, differential material balance equations. Then, by eliminating terms that are negligible, the simplest applicable set of equations remains to be solved. The generic form applies over a unit cross-sectional area and constant volume:

$$\frac{\partial \rho_j}{\partial t} = -\nabla \cdot n_j + r_j \tag{5-193a}$$

where $n_j = \rho v_j$. Applying Fick's law and expressing composition as concentration give

$$\frac{\partial c_j}{\partial t} = -v \cdot \nabla c_j + D_j \nabla^2 c_j + r_j \tag{5-193b}$$

Table 5-9 provides material balances for cartesian, cylindrical, and spherical coordinates.

**TABLE 5-9 Continuity Equation in Various Coordinate Systems**

| Coordinate system | Equation | |
|---|---|---|
| Cartesian | $\frac{\partial \rho_j}{\partial t} = -\left(\frac{\partial n_{x_j}}{\partial x} + \frac{\partial n_{y_j}}{\partial y} + \frac{\partial n_{z_j}}{\partial z}\right) + r_j$ | (5-194) |
| Cylindrical | $\frac{\partial \rho_j}{\partial t} = -\left(\frac{1}{r}\frac{\partial r n_{r_j}}{\partial r} + \frac{1}{r}\frac{\partial n_{\theta_j}}{\partial \theta} + \frac{\partial n_{z_j}}{\partial z}\right) + r_j$ | (5-195) |
| Spherical | $\frac{\partial \rho_j}{\partial t} = -\left(\frac{1}{r^2}\frac{\partial r^2 n_{r_j}}{\partial r} + \frac{1}{r \sin\theta}\frac{\partial n_{\theta_j} \sin\theta}{\partial \theta} + \frac{1}{r \sin\theta}\frac{\partial n_{\phi_j}}{\partial \phi}\right) + r_j$ | (5-196) |

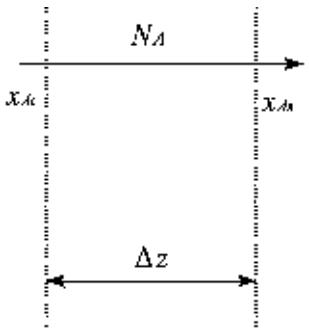

**FIG. 5-23** Hypothetical film and boundary conditions.

**Flux Expressions: Simple Integrated Forms of Fick's First Law** Simplified flux equations that arise from Eqs. (5-189) and (5-190) can be used for one-dimensional, steady-state problems with binary mixtures. The boundary conditions represent the compositions $x_{A_L}$ and $x_{A_R}$ at the left-hand and right-hand sides, respectively, of a hypothetical layer having thickness $\Delta z$. The principal restriction of the following equations is that the concentration and diffusivity are assumed to be constant. As written, the flux is positive from left to right, as depicted in Fig. 5-23.

1. Equimolar counterdiffusion ($N_A = -N_B$)

$$N_A = {}_M J_A = -D_{AB}\, c \frac{dx_A}{dz} = \frac{D_{AB}}{\Delta z}\, c\,(x_{A_L} - x_{A_R}) \tag{5-197}$$

2. Unimolar diffusion ($N_A \neq 0$, $N_B = 0$)

$$N_A = {}_M J_A + x_A N_A = \frac{D_{AB}}{\Delta z}\, c \ln \frac{1 - x_{A_R}}{1 - x_{A_L}} \tag{5-198}$$

3. Steady-state diffusion ($N_A \neq -N_B \neq 0$)

$$N_A = {}_M J_A + x_A(N_A + N_B) = \frac{N_A}{N_A + N_B} \frac{D_{AB}}{\Delta z} c \ln \left( \frac{\frac{N_A}{N_A + N_B} - x_{A_R}}{\frac{N_A}{N_A + N_B} - x_{A_L}} \right) \tag{5-199}$$

The unfortunate aspect of the last relationship is that one must know a priori the ratio of the fluxes to determine the magnitudes. It is not possible to solve simultaneously the pair of equations that apply for components $A$ and $B$ because the equations are not independent.

## DIFFUSIVITY ESTIMATION—GASES

Whenever measured values of diffusivities are available, they should be used. Typically, measurement errors are less than those associated with predictions by empirical or even semitheoretical equations. A few general sources of data can be found in Sec. 2 of this handbook; e.g., experimental values for gas mixtures are listed in Table 2-141. Other pertinent references are Schwartzberg and Chao (1982); Poling et al. (2001); Gammon et al. (1994); and Daubert and Danner (1989–1995). Many other more restricted sources are listed under specific topics later in this subsection.

Before diffusivities from either data or correlations are used, it is a good idea to check their reasonableness with respect to values that have been commonly observed in similar situations. Table 5-10 is a compilation of several rules of thumb. These values are not authoritative; they simply represent guidelines based on experience.

Diffusivity correlations for gases are outlined in Table 5-11. Specific parameters for individual equations are defined in the specific text regarding each equation. References are given at the beginning of the Mass Transfer subsection. The errors reported for Eqs. (5-200) through (5-203) were compiled by Poling et al. (2001), who compared the predictions with 68 experimental values of $D_{AB}$. Errors cited for Eqs. (5-204) to (5-209) were reported by the authors.

**Binary Mixtures at Low Pressure with Nonpolar Components** Many evaluations of correlations are available [Elliott and Watts, *Can. J. Chem.* **50:** 31 (1972); Lugg, *Anal. Chem.* **40:** 1072 (1968); Marrero and Mason, *AIChE J.* **19:** 498 (1973)]. The differences in accuracy of the correlations are minor, and thus the major concern is ease of calculation. The Fuller-Schettler-Giddings equation is usually the simplest correlation to use and

**TABLE 5-10 Rules of Thumb for Diffusivities (See Cussler, Poling et al., Schwartzberg and Chao)**

| Continuous phase | $D_i$ magnitude, $m^2/s$ | $D_i$ magnitude, $cm^2/s$ | $D_i$ range, $m^2/s$ | $D_i$ range, $cm^2/s$ | Comments |
|---|---|---|---|---|---|
| Gas at atmospheric pressure | $10^{-5}$ | 0.1 | $10^{-4}$–$10^{-6}$ | 1–$10^{-2}$ | Accurate theories exist, generally within ±10%; $D_iP \cong$ constant; $D_i \propto T^{1.66\text{ to }2.0}$ |
| Liquid | $10^{-9}$ | $10^{-5}$ | $10^{-8}$–$10^{-10}$ | $10^{-4}$–$10^{-6}$ | Approximate correlations exist, generally within ±25% |
| Liquid occluded in solid matrix | $10^{-10}$ | $10^{-6}$ | $10^{-8}$–$10^{-12}$ | $10^{-4}$–$10^{-8}$ | Hard cell walls: $D_{\text{eff}}/D_i = 0.1$ to 0.2. Soft cell walls: $D_{\text{eff}}/D_i = 0.3$ to 0.9 |
| Polymers and glasses | $10^{-12}$ | $10^{-8}$ | $10^{-10}$–$10^{-14}$ | $10^{-6}$–$10^{-10}$ | Approximate theories exist for dilute and concentrated limits; strong composition dependence |
| Solid | $10^{-14}$ | $10^{-10}$ | $10^{-10}$–$10^{-34}$ | $10^{-6}$–$10^{-30}$ | Approximate theories exist; strong temperature dependence |

**TABLE 5-11 Correlations of Diffusivities for Gases**

| Authors* | Equation | | Error, % |
|---|---|---|---|
| 1. Binary Mixtures—Low Pressure—Nonpolar | | | |
| Chapman-Enskog | $D_{AB} = \dfrac{0.001858T^{3/2}M_{AB}^{1/2}}{P\sigma_{AB}^2\Omega_D}$ | (5-200) | 7.3 |
| Wilke-Lee [22] | $D_{AB} = \dfrac{(0.00217 - 0.0005M_{AB}^{1/2})T^{3/2}M_{AB}^{1/2}}{P\sigma_{AB}^2\Omega_D}$ | (5-201) | 7.0 |
| Fuller-Schettler-Giddings [9] | $D_{AB} = \dfrac{0.001T^{1.75}M_{AB}^{1/2}}{P\left[(\Sigma\upsilon)_A^{1/3} + (\Sigma\upsilon)_B^{1/3}\right]^2}$ | (5-202) | 5.4 |
| 2. Binary Mixtures—Low Pressure—Polar | | | |
| Brokaw [3] | $D_{AB} = \dfrac{0.001858T^{3/2}M_{AB}^{1/2}}{P\sigma_{AB}^2\Omega_D}$ | (5-203) | 9.0 |
| 3. Self-Diffusivity | | | |
| Mathur-Thodos [14] | $D_{AA} = \dfrac{10.77\times10^{-5}T_r}{\beta\rho_r}\{\rho_r \le 1.5\}$ | (5-204) | 5 |
| Lee-Thodos [12—#1] | $D_{AA} = \dfrac{0.77\times10^{-5}T_r}{\rho_r\delta}\{\rho_r \le 1\}$ | (5-205) | 0.5 |
| Lee-Thodos [12—#2] | $D_{AA} = \dfrac{(0.007094G + 0.001916)^{2.5}T_r}{\delta}[\rho_r > 1, G < 1]$ | (5-206) | 17 |
| 4. Supercritical Mixtures | | | |
| Sun and Chen [18] | $D_{AB} = \dfrac{1.23\times10^{-10}T}{\mu^{0.799}V_{C_A}^{0.49}}$ | (5-207) | 5 |
| Catchpole and King [5] | $D_{AB} = 5.152\,D_cT_r\dfrac{(\rho^{-0.667} - 0.4510)(1 + M_A/M_B)R}{(1 + (V_{C_B}/V_{C_A})^{0.333})^2}$ | (5-208) | 10 |
| He and Yu [11] | $D_{AB} = \alpha(V_A^k - \beta)\sqrt{\dfrac{T}{M}},\quad \alpha = 10^{-5}\left[0.56392 + 2.1417\exp\left(\dfrac{-0.95088\sqrt{M_AV_{C_A}}}{P_{C_A}}\right)\right]$ | (5-209) | 6.9 |
| | $\beta = 8.9061 + 0.93858\dfrac{\sqrt{M_AV_{C_A}}}{P_{C_A}},\quad k = \dfrac{2}{3}[1 - 0.28\exp(-0.3\sqrt{M_A}\rho\iota_A)]$ | | |

*References are listed at the beginning of the Mass Transfer subsection.

**TABLE 5-12 Estimates for $\varepsilon_i$ and $\sigma_i$ (K, Å, atm, cm³, mol)**

| | | |
|---|---|---|
| Critical point | $\varepsilon/k = 0.75\ T_c$ | $\sigma = 0.841\ V_c^{1/3}$ or $2.44\ (T_c/P_c)^{1/3}$ |
| Critical point | $\varepsilon/k = 65.3\ T_c z_c^{3.6}$ | $\sigma = \dfrac{1.866\ V_c^{1/3}}{z_c^{1.2}}$ |
| Normal boiling point | $\varepsilon/k = 1.15\ T_b$ | $\sigma = 1.18\ V_b^{1/3}$ |
| Melting point | $\varepsilon/k = 1.92\ T_m$ | $\sigma = 1.222\ V_m^{1/3}$ |
| Acentric factor | $\varepsilon/k = (0.7915 + 0.1693\ \omega)\ T_c$ | $\sigma = (2.3551 - 0.087\ \omega)\left(\dfrac{T_c}{P_c}\right)^{1/3}$ |

NOTE: These values may not agree closely, so usage of a consistent basis is suggested (e.g., data at the normal boiling point).

is recommended by Poling et al. In several of the correlations, the average molecular weight $M_{AB}$ is defined as

$$M_{AB} = 1/[(1/M_A) + (1/M_B)] \tag{5-210}$$

***Chapman-Enskog (Bird et al.) and Wilke and Lee [22]*** The inherent assumptions of these equations are quite restrictive (i.e., low density, spherical atoms), and the intrinsic potential function is empirical. Despite that, they provide good estimates of $D_{AB}$ for many polyatomic gases and gas mixtures, up to about 1000 K and a maximum of 70 atm. The latter constraint exists because observations for many gases indicate that $D_{AB}P$ is constant up to 70 atm.

The characteristic length is $\sigma_{AB} = (\sigma_A + \sigma_B)/2$ in angstroms. To estimate the collision integral $\Omega_D$ for Eq. (5-202) or (5-203), two empirical equations are available. The first is

$$\Omega_D = (44.54T^{*-4.909} + 1.911T^{*-1.575})^{0.10} \tag{5-211a}$$

where $T^* = kT/\varepsilon_{AB}$ and $\varepsilon_{AB} = (\varepsilon_A\varepsilon_B)^{1/2}$. Estimates for $\sigma_i$ and $\varepsilon_i$ are given in Table 5-12. This expression shows that $\Omega_D$ is proportional to temperature roughly to the −0.49 power at low temperatures and to the −0.16 power at high temperature. Thus, gas diffusivities are proportional to temperatures to the 2.0 power and 1.66 power, respectively, at low and high temperatures. The second is

$$\Omega_D = \frac{A}{T^{*B}} + \frac{C}{\exp(DT^*)} + \frac{E}{\exp(FT^*)} + \frac{G}{\exp(HT^*)} \tag{5-211b}$$

where $A = 1.06036$, $B = 0.15610$, $C = 0.1930$, $D = 0.47635$, $E = 1.03587$, $F = 1.52996$, $G = 1.76474$, and $H = 3.89411$.

***Fuller, Schettler, and Giddings [9]*** The parameters and constants for this correlation were determined by regression analysis of 340 experimental diffusion coefficient values of 153 binary systems. Values of $\Sigma\upsilon_i$ used in this equation are found in Table 5-13.

**Binary Mixtures at Low Pressure with Polar Components** The *Brokaw* [3] correlation was based on the Chapman-Enskog equation, but $\sigma_{AB^*}$ and $\Omega_{D^*}$ were evaluated with a modified Stockmayer potential for polar molecules. Hence, slightly different symbols are used. That potential model reduces to the Lennard-Jones 6-12 potential for interactions between nonpolar molecules. As a result, the method should yield accurate predictions for polar as well as nonpolar gas mixtures. Brokaw presented data for 9 relatively polar pairs along with the prediction. The agreement was good:

**TABLE 5-13 Atomic Diffusion Volumes for Use in Estimating $D_{AB}$ by the Method of Fuller, Schettler, and Giddings [9]**

| Atomic and Structural Diffusion–Volume Increments, $\upsilon_i$ (cm³/mol) | | | |
|---|---|---|---|
| C | 16.5 | (Cl) | 19.5 |
| H | 1.98 | (S) | 17.0 |
| O | 5.48 | Aromatic ring | −20.2 |
| (N) | 5.69 | Heterocyclic ring | −20.2 |
| **Diffusion Volumes for Simple Molecules, $\Sigma\upsilon_i$ (cm³/mol)** | | | |
| $H_2$ | 7.07 | CO | 18.9 |
| $D_2$ | 6.70 | $CO_2$ | 26.9 |
| He | 2.88 | $N_2O$ | 35.9 |
| $N_2$ | 17.9 | $NH_3$ | 14.9 |
| $O_2$ | 16.6 | $H_2O$ | 12.7 |
| Air | 20.1 | $(CCl_2F_2)$ | 114.8 |
| Ar | 16.1 | $(SF_5)$ | 69.7 |
| Kr | 22.8 | $(Cl_2)$ | 37.7 |
| (Xe) | 37.9 | $(Br_2)$ | 67.2 |
| Ne | 5.59 | $(SO_2)$ | 41.1 |

Parentheses indicate that the value listed is based on only a few data points.

an average absolute error of 6.4 percent, considering the complexity of some of the gas pairs [e.g., $(CH_3)_2O$ and $CH_3Cl$]. Despite that, Poling et al. (2001) found the average error was 9.0 percent for combinations of mixtures (including several polar-nonpolar gas pairs), temperatures, and pressures. In this equation, $\Omega_D$ is calculated as described previously, and other terms are

$$\Omega_{D^*} = \Omega_D + 0.19\delta^2_{AB}/T^* \qquad T^* = kT/\varepsilon_{AB^*}$$
$$\sigma_{AB^*} = (\sigma_{A^*}\sigma_{B^*})^{1/2} \qquad \sigma_{i^*} = [1.585V_{bi}/(1 + 1.3\delta_i^2)]^{1/3}$$
$$\delta_{AB} = (\delta_A\delta_B)^{1/2} \qquad \delta_i = 1.94 \times 10^3\ \mu_i^2/V_{bi}T_{bi}$$
$$\varepsilon_{AB^*} = (\varepsilon_{A^*}\varepsilon_{B^*})^{1/2} \qquad \varepsilon_{i^*}/k = 1.18\ (1 + 1.3\delta_i^2)T_{bi}$$

**Binary Mixtures at High Pressure** Of the various categories of gas-phase diffusion, this is the least studied. This is so because the effects of diffusion are easily distorted by even a slight pressure gradient, which is difficult to avoid at high pressure. Harstad and Bellan [*Ind. Eng. Chem. Res.* **43:** 645 (2004)] developed a corresponding-states expression that extends the Chapman-Enskog method, covered earlier. They express the diffusivity at high pressure by accounting for the reduced temperature, and they suggest employing an equation of state and shifting from

$$D^o_{AB} = f(T, P) \text{ to } D_{AB} = g(T, V).$$

**Self-Diffusivity** Self-diffusivity is rarely used for solving separation problems. Despite that, it has been studied extensively under high pressures, e.g., greater than 70 atm. There are few accurate estimation methods for mutual diffusivities at such high pressures, because composition measurements are difficult.

The general observation for gas-phase diffusion $D_{AB}P$ = constant, which holds at low pressure, is not valid at high pressure. Rather, $D_{AB}P$ decreases as pressure increases. In addition, composition effects, which frequently are negligible at low pressure, are very significant at high pressure. Suárez-Iglesias et al. [*J. Chem. Engg. Data* **60:** 2757 (2015)] published a thorough review of experimental self-diffusivities of gases, vapors, and liquids, ranging from noble gases and simple diatomics to complex organic molecules. The methods included both tracer techniques and nuclear magnetic resonance.

Liu and Ruckenstein [*Ind. Eng. Chem. Res.* **36:** 3937 (1997)] studied self-diffusion for both liquids and gases. They compared their estimates to 26 pairs, with a total of 1822 data points, and achieved a relative deviation of 7.3 percent. Zielinski and Hanley [*AIChE J.* **45:** 1 (1999)] developed a model to predict multicomponent diffusivities from self-diffusion coefficients and thermodynamic information. Mathur and Thodos [14] showed that for reduced densities less than unity, the product $D_{AA}\rho$ is approximately constant at a given temperature. In their correlation, $\beta = M_A^{1/2}P_C^{1/3}/T_C^{5/6}$. Lee and Thodos [12] presented generalized correlations of self-diffusivity for gases (and liquids), which have been tested for more than 500 data points each, with an average deviation of the first of 0.51 percent, and that of the second is 17.2 percent. $\delta = M_A^{1/2}/P_C^{1/2}V_C^{5/6}$, s/cm², and where $G = (X^* - X)/(X^* - 1)$, $X = \rho_r/T_r^{0.1}$, and $X^* = \rho_r/T_r^{0.1}$ evaluated at the solid melting point. Lee and Thodos [*Ind. Eng. Chem. Res.* **27:** 17 (1988)] expanded their earlier treatment of self-diffusivity to cover 58 substances and 975 data points, with an average absolute deviation of 5.26 percent. Liu, Silva, and Macedo [*Chem. Eng. Sci.* **53:** 2403 (1998)] and Silva, Liu, and Macedo [*Chem. Eng. Sci.* **53:** 2423 (1998)] present a theoretical approach. For 2047 data points with nonpolar species, their best model yielded 4.5 percent average deviation, while the Lee-Thodos equation yielded 5.2 percent. The new model was also much better than all the other models for over 424 data points with polar species, yielding 4.3 percent deviation, while the Lee-Thodos equation yielded 34 percent.

**Supercritical Mixtures** Debenedetti and Reid [*AIChE J.* **32:** 2034 (1986) and **33:** 496 (1987)] showed that conventional correlations based on the Stokes-Einstein relation (for liquid phase) tend to overpredict diffusivities in the supercritical state. Nevertheless, they observed that the Stokes-Einstein group $D_{AB}\mu/T$ was constant. Thus, although no general

correlation applies, only one data point is necessary to examine variations of fluid viscosity and/or temperature effects. Sun and Chen [18] examined tracer diffusion data of aromatic solutes in alcohols up to the supercritical range and found their data correlated with average deviations of 5 percent and a maximum deviation of 17 percent for their rather limited set of data. Catchpole and King [5] examined binary diffusion data of near-critical fluids in the reduced density range of 1 to 2.5 and found average deviations of 10 percent and a maximum deviation of 60 percent. Liu and Ruckenstein [*Ind. Eng. Chem. Res.* **36:** 888 (1997)] presented a semiempirical equation to estimate diffusivities under supercritical conditions that is based on the Stokes-Einstein relation and the long-range correlation, respectively. They compared their estimates to 33 pairs, 598 data points, and achieved lower deviations (5.7 percent) than the Sun-Chen correlation (13.3 percent) and the Catchpole-King equation (11.0 percent). He and Yu [11] presented a semiempirical equation to estimate diffusivities under supercritical conditions that is based on hard-sphere theory. It is limited to $\rho_r \geq 0.21$, where the reduced density is $\rho_r = \rho_A(T, P)/\rho_{C\,A}$. They compared their estimates to 107 pairs, 1167 data points, and achieved lower deviations (7.8 percent) than the Catchpole-King equation (9.7 percent), which was restricted to $\rho_r \geq 1$. Silva and Macedo [*Ind. Eng. Chem. Res.* **37:** 1490 (1998)] measured diffusivities of ethers in $CO_2$ under supercritical conditions and compared them to the Wilke-Chang [Eq. (5-214)], Tyn-Calus [Eq. (5-215)], Catchpole-King [Eq. (5-208)], and their own equations. They found that the Wilke-Chang equation provided the best fit. Gonzalez, Bueno, and Medina [*Ind. Eng. Chem. Res.* **40:** 3711 (2001)] measured diffusivities of aromatic compounds in $CO_2$ under supercritical conditions and compared them to the Wilke-Chang [Eq. (5-215)], Hayduk-Minhas [Eq. (5-223)], and other equations. They recommended the Wilke-Chang equation (which yielded a relative error of 10.1 percent) but noted that the He and Yu equation provided the best fit (5.5 percent).

**Low-Pressure/Multicomponent Mixtures** Smith and Taylor [*Ind. Eng. Chem. Fundam.* **22:** 97 (1983)] compared various methods for predicting multicomponent diffusion rates and found that the Maxwell-Stefan approach (see later section) was superior.

Blanc [*J. Phys.* **7:** 825 (1908)] provided a simple limiting case for dilute component *i* diffusing in a stagnant medium (that is, $N \approx 0$), and the result is known as *Blanc's law*.

$$D_{im} = \left( \sum_{j=1}^{N_C} \frac{x_j}{D_{ij}} \right)^{-1} \tag{5-212}$$

The restriction basically means that the compositions of all the components, besides component *i,* are relatively large and uniform.

## DIFFUSIVITY ESTIMATION—LIQUIDS

Many more correlations are available for diffusion coefficients in the liquid phase than for the gas phase. Most, however, are restricted to binary diffusion at infinite dilution $D^{\circ}_{AB}$ or to self-diffusivity $D_{A'A}$. This reflects the much greater complexity of liquids on a molecular level. For example, gas-phase diffusion exhibits negligible composition effects and deviations from thermodynamic ideality. Conversely, liquid-phase diffusion usually involves volumetric and thermodynamic effects due to composition variations. For concentrations greater than a few mole percent of *A* and *B,* corrections are needed to obtain the true diffusivity. Furthermore, many conditions do not fit any of the correlations presented here. Thus, careful consideration is needed to produce a reasonable estimate. Again, if diffusivity data are available at the conditions of interest, then they are strongly preferred over the predictions of any correlations. Experimental values for liquid mixtures are listed in Table 2-142.

**Stokes-Einstein and Free-Volume Theories** The starting point for many correlations is the Stokes-Einstein equation. This equation is derived from continuum fluid mechanics and classical thermodynamics for the motion of large spherical particles in a liquid. For this case, the need for a molecular theory is cleverly avoided. The Stokes-Einstein equation is (Bird et al.)

$$D_{AB} = \frac{kT}{6\pi r_A \mu_B} \tag{5-213}$$

where *A* refers to the solute and *B* refers to the solvent. This equation is applicable to very large unhydrated molecules ($M > 1000$) in low-molecular-weight solvents or where the molar volume of the solute is greater than 500 $cm^3$/mol (Reddy and Doraiswamy, *Ind. Eng. Chem. Fundam.* **6:** 77 (1967); Wilke and Chang [21]). Despite its intellectual appeal, this equation is seldom used "as is." Rather, the following principles have been identified: (1) The diffusion coefficient is inversely proportional to the size $r_A \simeq V_A^{1/3}$ of the solute molecules. Experimental observations, however, generally indicate that the exponent of the solute molar volume is larger than one-third. (2) The term $D_{AB}\mu_B/T$ is approximately constant only over a 10 to 15 K interval. Thus, the dependence of liquid diffusivity on properties and conditions does not generally obey the interactions implied by that grouping. For example, Robinson, Edmister, and Dullien [*Ind. Eng. Chem. Fundam.* **5:** 75 (1966)] found that $\ln D_{AB} \propto -1/T$. (3) Finally, pressure does not affect liquid-phase diffusivity much, since $\mu_B$ and $V_A$ are only weakly pressure-dependent. Pressure does have an impact at very high levels.

Another advance in the concepts of liquid-phase diffusion was provided by Hildebrand [*Science* **174:** 490 (1971)] who adapted a theory of viscosity to self-diffusivity. He postulated that $D_{A'A} = B(V - V_{ms})/V_{ms}$, where $D_{A'A}$ is the self-diffusion coefficient, $V$ is the molar volume, and $V_{ms}$ is the molar volume at which fluidity is zero (i.e., the molar volume of the solid phase at the melting temperature). The difference $V - V_{ms}$ can be thought of as the free volume, which increases with temperature; and $B$ is a proportionality constant.

Ertl and Dullien (*AIChE J.* **19:** 1215 (1973)) found that Hildebrand's equation could not fit their data with $B$ as a constant. They modified it by applying an empirical exponent $n$ (a constant greater than unity) to the volumetric ratio. The new equation is not generally useful, however, since there is no means for predicting $n$. The theory does identify the free volume as an important physical variable, since $n > 1$ for most liquids implies that diffusion is more strongly dependent on free volume than is viscosity.

**Dilute Binary Nonelectrolytes: General Mixtures** These correlations are outlined in Table 5-14.

***Wilke-Chang [22]*** This correlation for $D^{\circ}_{AB}$, which is an empirical modification of the Stokes-Einstein equation, is one of the most widely used. It is not very accurate, however, for water as the solute. Otherwise, it applies to diffusion of very dilute *A* in *B.* The average absolute error for 251 different systems is about 10 percent; $\phi_B$ is an association factor of solvent *B* that accounts for hydrogen bonding.

| Component *B* | $\phi_B$ |
|---|---|
| Water | 2.26 |
| Methanol | 1.9 |
| Ethanol | 1.5 |
| Propanol | 1.2 |
| Others | 1.0 |

The value of $\phi_B$ for water was originally stated as 2.6, although when the original data were reanalyzed, the empirical best fit was 2.26. Random comparisons of predictions with 2.26 versus 2.6 show no consistent advantage for either value, however. Kooijman [*Ind. Eng. Chem. Res.* **41:** 3326 (2002)] suggests replacing $V_A$ with $\theta_A V_A$, in which $\theta_A = 1$ except when $A$ = water, $\theta_A = 4.5$. This modification leads to an overall error of 8.7 percent for 41 cases he compared. He suggests retaining $\phi_B = 2.6$ when $B$ = water. It has been suggested to replace the exponent of 0.6 with 0.7 and to use an association factor of 0.7 for systems containing aromatic hydrocarbons. These modifications, however, are not recommended by Umesi and Danner [*Ind. Eng. Chem. Process Des. Dev.* **20:** 662 (1981)], who developed an equation for nonaqueous solvents with nonpolar and polar solutes. The average absolute deviation was 16 percent, compared with 26 percent for the Wilke-Chang equation. Lees and Sarram [*J. Chem. Eng. Data* **16:** 41 (1971)] compare the association parameters. The average absolute error for 87 different solutes in water is 5.9 percent.

***Tyn-Calus [19]*** This correlation requires data in the form of molar volumes and parachors $\psi_i = V_i\sigma_i^{1/4}$ (a property which, over moderate temperature ranges, is nearly constant), measured at the same temperature (not necessarily the temperature of interest). The parachors for the components may also be evaluated at different temperatures from one another. Quale [*Chem. Rev.* **53:** 439 (1953)] compiled values of $\psi_i$ for many chemicals. Group contribution methods are available for estimation purposes (Poling et al.). The following suggestions were made by Poling et al.: The correlation is constrained to cases in which $\mu_B < 30$ cP. If the solute is water or if the solute is an organic acid and the solvent is not water or a short-chain alcohol, then dimerization of solute *A* should be assumed for purposes of estimating its volume and parachor. For example, the appropriate values for water as solute at 25°C are $V_W = 37.4$ $cm^3$/mol and $\psi_W = 105.2$ $cm^3g^{1/4}/s^{1/2}$ mol. Finally, if the solute is nonpolar, the solvent volume and parachor should be multiplied by $8\mu_B$. According to Kooijman [*Ind. Eng. Chem. Res.* **41:** 3326 (2002)], if the Brock-Bird method (described in Poling et al.) is used to estimate the surface tension, the error is only increased by about 2 percent, relative to employing experimentally measured values.

***Siddiqi-Lucas [17]*** In an impressive empirical study, these authors examined 1275 organic liquid mixtures. Their equation yielded an average absolute deviation of 13.1 percent, which was less than that for the Wilke-Chang equation (17.8 percent). Note that Eq. (5-216) does not encompass aqueous solutions, which are correlated in Eq. (5-218).

**TABLE 5-14 Correlations for Diffusivities of Dilute, Binary Mixtures of Nonelectrolytes in Liquids**

| Authors* | Equation | | Error |
|---|---|---|---|
| 1. General Mixtures | | | |
| Wilke-Chang [21] | $D^o_{AB} = \dfrac{7.4\times10^{-8}(\phi_B M_B)^{1/2}T}{\mu_B V_A^{0.6}}$ | (5-214) | 20% |
| Tyn-Calus [19] | $D^o_{AB} = \dfrac{8.93\times10^{-8}(V_A/V_B^2)^{1/6}(\psi_B/\psi_A)^{0.6}T}{\mu_B}$ | (5-215) | 10% |
| Siddiqi-Lucas [17] | $D^o_{AB} = \dfrac{9.89\times10^{-8}(V_B^{0.265})T}{V_A^{0.45}\mu_B^{0.907}}$ | (5-216) | 13% |
| 2. Gases in Low-Viscosity Liquids | | | |
| Chen-Chen [6] | $D^o_{AB} = 2.018\times10^{-9}\dfrac{(\beta V_{C_B})^{2/3}(RT_{C_B})^{1/2}}{M_A^{1/6}(M_B V_{C_A})^{1/3}}(V_r-1)\left(\dfrac{T}{T_{C_B}}\right)^{1/2}$ | (5-217) | 6% |
| 3. Aqueous Solutions | | | |
| Siddiqi-Lucas [17] | $D^o_{AW} = 2.98\times10^{-7}V_A^{-0.5473}\mu_w^{-1.026}T$ | (5-218) | 13% |
| 4. Hydrocarbon Mixtures | | | |
| Hayduk-Minhas [10] | $D^o_{AB} = 13.3\times10^{-8}T^{1.47}\mu_B^{(10.2/V_A-0.791)}V_A^{-0.71}$ | (5-219) | 5% |
| Matthews-Akgerman [15] | $D^o_{AB} = 32.88M_A^{-0.61}V_D^{-1.04}T^{0.5}(V_B-V_D)$ | (5-220) | 5% |

**Binary Mixtures of Gases in Low-Viscosity, Nonelectrolyte Liquids** Sridhar and Potter [*AIChE J.* **23:** 4, 590 (1977)] derived an equation for predicting gas diffusion through liquid by combining existing correlations. Hildebrand had postulated the following dependence of the diffusivity for a gas in a liquid: $D^o_{AB} = D_{B'B}(V_{cB}/V_{cA})^{2/3}$, where $D_{B'B}$ is the solvent self-diffusion coefficient and $V_{ci}$ is the critical volume of component *i,* respectively. To correct for minor changes in volumetric expansion, Sridhar and Potter multiplied the resulting equation by $V_B/V_{mlB}$, where $V_{mlB}$ is the molar volume of the liquid *B* at its melting point. They compared experimentally measured diffusion coefficients for 27 data points of 11 binary mixtures. Their average absolute error was 13.5 percent. This correlation demonstrates the usefulness of self-diffusion as a means to assess mutual diffusivities and the value of observable physical property changes, such as molar expansion, to account for changes in conditions.

***Chen-Chen [6]*** Their correlation was based on diffusion measurements of 50 combinations of conditions with 3 to 4 replicates each and exhibited an average error of 6 percent. In this correlation, $V_r = V_B/[0.9724(V_{mlB}+0.04765)]$ and $V_{mlB}$ = the liquid molar volume at the melting point, as discussed previously. Their association parameter $\beta$ [which is different from the definition of that symbol in Eq. (5-221)] accounts for hydrogen bonding of the solvent. Values for acetonitrile and methanol are $\beta = 1.58$ and 2.31, respectively.

**Dilute Binary Mixtures of a Nonelectrolyte in Water** The correlations that were suggested previously for general mixtures, unless specified otherwise, may also be applied to diffusion of miscellaneous solutes in water. The following correlations are restricted to aqueous systems.

Hayduk and Laudie [*AIChE J.* **20:** 3, 611 (1974)] presented a simple correlation for the infinite dilution diffusion coefficients of nonelectrolytes in water. It has about the same accuracy as the Wilke-Chang equation (about 5.9 percent). There is no explicit temperature dependence, but the variation in water viscosity compensates for the absence of temperature.

***Siddiqi and Lucas [17]*** These authors examined 658 aqueous liquid mixtures in an empirical study. They found an average absolute deviation of 19.7 percent. In contrast, the Wilke-Chang equation gave 35.0 percent and the Hayduk-Laudie correlation gave 30.4 percent.

**Dilute Binary Hydrocarbon Mixtures** Hayduk and Minhas [10] presented an accurate correlation for normal paraffin mixtures that was developed from 58 data points consisting of solutes from $C_5$ to $C_{32}$ and solvents from $C_5$ to $C_{16}$. The average error was 3.4 percent for the 58 mixtures.

***Matthews and Akgerman [15]*** The free-volume approach of Hildebrand was shown to be valid for binary, dilute liquid paraffin mixtures (as well as self-diffusion), consisting of solutes from $C_8$ to $C_{16}$ and solvents of $C_6$ and $C_{12}$. The term they referred to as the "diffusion volume" was simply correlated with the critical volume, as $V_D = 0.308V_c$. We can infer from Table 5-11 that this is approximately related to the volume at the melting point as $V_D = 0.945V_m$. Their correlation was valid for diffusion of linear alkanes at temperatures up to 300°C and pressures up to 3.45 MPa. Matthews, Rodden, and Akgerman [ *J. Chem. Eng. Data* **32:** 317 (1987)] and Erkey and Akgerman [*AIChE J.* **35:** 443 (1989)] completed similar studies of diffusion of alkanes, restricted to *n*-hexadecane and *n*-octane, respectively, as the solvents.

Riazi and Whitson [*Ind. Eng. Chem. Res.* **32:** 3081 (1993)] presented a generalized correlation in terms of viscosity and molar density that was applicable to both gases and liquids. The average absolute deviation for gases was only about 8 percent, while for liquids it was 15 percent. Their expression relies on the Chapman-Enskog correlation [Eq. (5-200)] for the low-pressure diffusivity and correlations for low-pressure viscosity.

**Dilute Binary Mixtures of Nonelectrolytes with Water as the Solute** Olander [*AIChE J.* **7:** 175 (1961)] modified the Wilke-Chang equation to adapt it to the infinite dilution diffusivity of water as the solute. The modification he recommended is simply the division of the right-hand side of the Wilke-Chang equation by 2.3. Unfortunately, neither the Wilke-Chang equation nor that equation divided by 2.3 fit the data very well. A reasonably valid generalization is that the Wilke-Chang equation is accurate if water is very insoluble in the solvent, such as pure hydrocarbons, halogenated hydrocarbons, and nitro-hydrocarbons. On the other hand, the Wilke-Chang equation divided by 2.3 is accurate for solvents in which water is very soluble, as well as those that have low viscosities. Such solvents include alcohols, ketones, carboxylic acids, and aldehydes. Neither equation is accurate for higher-viscosity liquids, especially diols.

**Dilute Dispersions of Macromolecules in Nonelectrolytes** The Stokes-Einstein equation predicts accurately the diffusion coefficient of spherical latex particles and globular proteins. Corrections to Stokes-Einstein for molecules approximating spheroids are given by Tanford [*Physical Chemistry of Macromolecules,* Wiley, New York, 1961]. Since solute-solute interactions are ignored in this theory, it applies in the dilute range only.

***Hiss and Cussler*** *[AIChE J.* ***19:*** *698 (1973)]* Their basis is the diffusion of a small solute in a fairly viscous solvent of relatively large molecules, which is the opposite of the Stokes-Einstein assumptions. The large solvent molecules investigated were not polymers or gels but were of moderate molecular weight so that the macroscopic and microscopic viscosities were the same. The major conclusion is that $D^\circ_{AB}\mu^{2/3}$ = constant at a given temperature and for a solvent viscosity from $5\times10^{-3}$ to 5 Pa · s or greater (5 to $5\times10^3$ cP). This observation is useful if $D^\circ_{AB}$ is known in a given high-viscosity liquid (oils, tars, etc.). Use of the usual relation of $D^\circ_{AB} \propto 1/\mu$ for such an estimate could lead to large errors.

**Concentrated Binary Mixtures of Nonelectrolytes** Since the infinite dilution values $D^\circ_{AB}$ and $D^\circ_{BA}$ are generally unequal, even a thermodynamically

ideal solution like $\gamma_A = \gamma_B = 1$ will exhibit concentration dependence of the diffusivity. In addition, nonideal solutions require the following thermodynamic correction factor because the true "driving force" is the chemical potential gradient, not the composition gradient.

$$\beta_A = 1 + \frac{\partial \ln \gamma_A}{\partial \ln x_A} \tag{5-221}$$

Darken [*Trans. Am. Inst. Mining Met. Eng.* **175:** 184 (1948)] observed that solid-state diffusion in metallurgical applications followed a simple relation. His equation related the tracer diffusivities and mole fractions to the mutual diffusivity:

$$D_{AB} = (x_A D_B + x_B D_A)\beta_A \tag{5-222}$$

Several correlations that predict the composition dependence of $D_{AB}$ are summarized in Table 5-15. Most are based on known values of $D^\circ_{AB}$ and $D^\circ_{BA}$. In fact, a rule of thumb states that, for many binary systems, $D^\circ_{AB}$ and $D^\circ_{BA}$ bound the $D_{AB}$ vs. $x_A$ curve.

Caldwell and Babb [4] used virtually Darken's equation to evaluate the mutual diffusivity for concentrated mixtures of common liquids.

Van Geet and Adamson [*J. Phys. Chem.* **68:** 238 (1964)] tested that equation for the *n*-dodecane (*A*) and *n*-octane (*B*) system and found the average deviation of $D_{AB}$ from experimental values to be −0.68 percent. Additional tests showed Eq. (5-223) can be expected to be fairly accurate for nonpolar hydrocarbons of similar molecular weight. For systems that depart significantly from thermodynamic ideality, such as polar-polar mixtures, it breaks down, sometimes by a factor of 8. Siddiqi, Krahn, and Lucas [*J. Chem. Eng. Data* **32:** 48 (1987)] found that this relation was superior to those of Vignes and Leffler and Cullinan for a variety of mixtures. Umesi and Danner [*Ind. Eng. Chem. Process Des. Dev.* **20:** 662 (1981)] found an average absolute deviation of 13.9 percent for 198 data points.

Rathbun and Babb [16] suggested that Darken's equation could be improved by raising the thermodynamic correction factor $\beta_A$ to a power $n$ less than unity. They looked at systems exhibiting negative deviations from Raoult's law and found $n = 0.3$. Furthermore, for polar-nonpolar mixtures, they found $n = 0.6$. Siddiqi and Lucas [17] followed those suggestions and found an average absolute error of 3.3 percent for nonpolar-nonpolar mixtures, 11.0 percent for polar-nonpolar mixtures, and 14.6 percent for polar-polar mixtures. Siddiqi, Krahn, and Lucas [*J. Chem. Eng. Data* **32:** 48 (1987)] examined a few other mixtures and found that $n = 1$ was probably best. Thus, this approach is, at best, highly dependent on the type of components.

Vignes [20] empirically correlated mixture diffusivity data for 12 binary mixtures. Later Ertl, Ghai, and Dollon [*AIChE J.* **20:** 1 (1974)] evaluated 122 binary systems, which showed an average absolute deviation of only 7 percent. None of the latter systems, however, was very nonideal.

Leffler and Cullinan [13] modified Vignes' equation using theoretical arguments to arrive at Eq. (5-226), which the authors compared to Eq. (5-225) for the 12 systems mentioned above. The average absolute maximum deviation was only 6 percent. Umesi and Danner [*Ind. Eng. Chem. Process Des. Dev.* **20:** 662 (1981)], however, found an average absolute deviation of 11.4 percent for 198 data points. For normal paraffins, it is not very accurate. In general, the accuracies of the two equations are not much different, and since Vignes' equation is simpler to use, it is suggested. The application of either should be limited to nonassociating systems that do not deviate much from ideality ($0.95 < \beta_A < 1.05$).

Cussler [8] showed that in concentrated associating systems it is the size of diffusing clusters rather than diffusing solutes that controls diffusion. $D_o$ is a reference diffusion coefficient discussed hereafter; $a_A$ is the activity of component *A*; and *K* is a constant. By assuming that $D_o$ could be predicted by Eq. (5-225) with $\beta = 1$, *K* was found to be equal to 0.5 based on five binary systems and validated with a sixth binary mixture. The limitations of Eq. (5-227) using $D_o$ and *K* defined previously have not been explored, so caution is warranted. Gurkan [*AIChE J.* **33:** 175 (1987)] showed that *K* should actually be closer to 0.3 (rather than 0.5) and discussed the overall results.

Cullinan [7] presented an extension of Cussler's cluster diffusion theory that contains no adjustable constants, does not use diffusivity values at infinite dilution, and relates transport properties and solution thermodynamics. His method accurately accounts for composition and temperature dependence of diffusivity; however, it requires accurate density, viscosity, and activity coefficient data. This equation has been tested for six very different mixtures by Rollins and Knaebel [*AIChE J.* **37:** 470 (1991)], and it was found to agree remarkably well with data for most conditions, considering the absence of empirical parameters (including diffusivity values). In the dilute region (of either *A* or *B*), there are systematic errors probably caused by the breakdown of certain implicit assumptions (that nevertheless appear to be generally valid at higher concentrations).

Asfour and Dullien [1] developed a relation for predicting alkane diffusivities at moderate concentrations that employs

$$\zeta = \left( \frac{V_{fm}}{V_{fx_A} V_{fx_B}} \right)^{2/3} \frac{M_{x_A} M_{x_B}}{M_m} \tag{5-233a}$$

where $V_{fx_i} = V_{fi}^{x_i}$; the fluid free volume is $V_{fi} = V_i - V_{mli}$ for $i = A, B,$ and $m,$ in which $V_{mli}$ is the molar volume of the liquid at the melting point and

$$V_{ml_m} = \left( \frac{x_A^2}{V_{ml_A}} + \frac{2x_A x_B}{V_{ml_{AB}}} + \frac{x_B^2}{V_{ml_B}} \right)^{-1} \tag{5-233b}$$

and

$$V_{ml_{AB}} = \left[ \frac{V_{ml_A}^{1/3} + V_{ml_B}^{1/3}}{2} \right]^3 \tag{5-233c}$$

and $m$ is the mixture viscosity, $M_m$ is the mixture mean molecular weight, and $\beta_A$ is defined by Eq. (5-221). The average absolute error of this equation is 1.4 percent, while the Vignes equation and the Leffler-Cullinan equation give 3.3 percent and 6.2 percent, respectively.

Siddiqi and Lucas [17] suggested that component volume fractions might be used to correlate the effects of concentration dependence. They found an average absolute deviation of 4.5 percent for nonpolar-nonpolar mixtures, 16.5 percent for polar-nonpolar mixtures, and 10.8 percent for polar-polar mixtures.

Bosse and Bart [2] added a term to account for excess Gibbs free energy, involved in the activation energy for diffusion, which was previously omitted. Doing so yielded minor modifications of the Vignes and Leffler-Cullinan equations [Eqs. (5-225) and (5-226), respectively]. The UNIFAC method was used to assess the excess Gibbs free energy. Comparing predictions of the new equations with data for 36 pairs and 326 data points yielded relative deviations of 7.8 percent and 8.9 percent, respectively, but which were better than the closely related Vignes (12.8 percent) and Leffler-Cullinan (10.4 percent) equations.

**Binary Electrolyte Mixtures** When electrolytes are added to a solvent, they dissociate to a certain degree. It would appear that the solution contains at least three components: solvent, anions, and cations. If the solution is to remain neutral in charge at each point (assuming the absence of any applied electric potential field), the anions and cations diffuse effectively as a single component, and diffusion can thus be treated as a binary mixture.

**TABLE 5-15 Correlations of Diffusivities for Concentrated, Binary Mixtures of Nonelectrolyte Liquids**

| Authors* | Equation | |
|---|---|---|
| Caldwell-Babb [4] | $D_{AB} = (x_A D^\circ_{BA} + x_B D^\circ_{AB})\beta_A$ | (5-223) |
| Rathbun-Babb [16] | $D_{AB} = (x_A D^\circ_{BA} + x_B D^\circ_{AB})\beta^n_A$ | (5-224) |
| Vignes [20] | $D_{AB} = D_{AB}^{\alpha x_B} D_{BA}^{\alpha x_A} \beta_A$ | (5-225) |
| Leffler-Cullinan [13] | $D_{AB}\mu_{mix} = (D^\circ_{AB}\mu_B)^{x_B}(D^\circ_{BA}\mu_A)^{x_A}\beta_A$ | (5-226) |
| Cussler [8] | $D_{AB} = D_0\left[1 + \frac{K}{x_A x_B}\left(\frac{\partial \ln x_A}{\partial \ln a_A} - 1\right)\right]^{-1/2}$ | (5-227) |
| Cullinan [7] | $D_{AB} = \frac{kT}{2\pi\mu_{mix}(V/A)^{1/3}}\left[\frac{2\pi x_A x_B \beta_A}{1 + \beta_A(2\pi x_A x_B - 1)}\right]^{1/2}$ | (5-228) |
| Asfour-Dullien [1] | $D_{AB} = \left(\frac{D^\circ_{AB}}{\mu_B}\right)^{x_B}\left(\frac{D^\circ_{BA}}{\mu_A}\right)^{x_A}\zeta\mu\beta_A$ | (5-229) |
| Siddiqi-Lucas [17] | $D_{AB} = (C_B\overline{V}_B D^\circ_{AB} + C_A\overline{V}_A D^\circ_{BA})\beta_A$ | (5-230) |
| Bosse and Bart no. 1 [2] | $D_{AB} = (D^\infty_{AB})^{X_B}(D^\infty_{AB})^{X_A}\exp\left(-\frac{g^E}{RT}\right)$ | (5-231) |
| Bosse and Bart no. 2 [2] | $\mu D_{AB} = (\mu\beta D^\infty_{AB})^{X_B}(\mu_A D^\infty_{BA})^{X_A}\exp\left(-\frac{g^E}{RT}\right)$ | (5-232) |

Relative errors for the correlations in this table are very dependent on the components of interest and are cited in the text.

*See the beginning of the Mass Transfer subsection for references.

***Nernst-Haskell*** The theory of dilute diffusion of salts is well developed and has been experimentally verified. For dilute solutions of a single salt, the well-known Nernst-Haskell equation (Poling et al.) is applicable:

$$D^{\circ}_{AB}\frac{RT}{F^2}\frac{\left|\frac{1}{n_+}\right|+\left|\frac{1}{n_-}\right|}{\frac{1}{\lambda^0_+}+\frac{1}{\lambda^0_-}}=8.9304\times10^{-10}T\frac{\left|\frac{1}{n_+}\right|+\left|\frac{1}{n_-}\right|}{\frac{1}{\lambda^0_+}+\frac{1}{\lambda^0_-}} \tag{5-234}$$

where $D^{\circ}_{AB}$ = diffusivity based on molarity rather than normality of dilute salt $A$ in solvent $B$, cm$^2$/s.

The previous equations can be interpreted in terms of ionic-species diffusivities and conductivities. The latter are easily measured and depend on temperature and composition. The resulting equation of the electrolyte diffusivity is

$$D_{AB}=\frac{|z_+|+|z_-|}{\left(|z_-|/D_+\right)+\left(|z_+|/D_-\right)} \tag{5-235}$$

where $|z_\pm|$ represents the magnitude of the ionic charge and where the cationic or anionic diffusivities are $D_\pm = 8.9304\times10^{-10}\,T\lambda_\pm/|z_\pm|$ cm$^2$/s and $\lambda_\pm$ are the infinite dilution conductances of cation and anion. In practice, the equivalent conductance of the ion pair of interest would be obtained and supplemented with conductances of permutations of those ions and one independent cation and anion. This would allow determination of all the ionic conductances and hence the diffusivity of the electrolyte solution.

According to Gordon [*J. Phys. Chem.* **5:** 522 (1937)] typically, as the concentration of a salt increases from infinite dilution, the diffusion coefficient decreases rapidly from $D^{\circ}_{AB}$. As concentration is increased further, however, $D_{AB}$ rises steadily, often becoming greater than $D^{\circ}_{AB}$. Gordon proposed the following empirical equation, which is applicable up to concentrations of 2$N$:

$$D_{AB}=D^{\circ}_{AB}\frac{1}{C_B\bar{V}_B}\frac{\mu_B}{\mu}\left(1+\frac{\ln\gamma_\pm}{\ln m}\right) \tag{5-236}$$

where $D^{\circ}_{AB}$ is given by the Nernst-Haskell equation. References that tabulate $\gamma_\pm$ as a function of $m$, as well as other equations for $D_{AB}$, are given by Poling et al.

Morgan, Ferguson, and Scovazzo [*Ind. Eng. Chem. Res.* **44:** 4815 (2005)] studied diffusion of gases in ionic liquids having moderate to high viscosity (up to about 1000 cP) at 30°C. Their range was limited, and the empirical equation they found was

$$D_{AB}=3.7\times10^{-3}\left(\frac{1}{\mu_B^{0.59}V_A\rho_B^2}\right) \tag{5-237}$$

which yielded a correlation coefficient of 0.975. Of the estimated diffusivities 90 percent were within ±20 percent of the experimental values. The exponent for viscosity approximately confirmed the observation of Hiss and Cussler [*AIChE J.* **19:** 698 (1973)].

***Example 5-15 Diffusivity Estimation***

*a.* Estimate the diffusivity of naphthalene ($A$) in nitrogen ($B$) at 30°C and 1 atm (abs).

1. Chapman-Enskog equation (refer to Table 5-11, Eqs. (5-200), (5-210), and (5-211*a*), and Table 5-12).

   We will use properties of naphthalene ($M_A$ = 128.17) at its melting point (353.5 K, $\rho_{LA}$ = 0.973 g/cm$^3$), and nitrogen ($M_B$ = 28.01) at its boiling point (77.4 K, $\rho_{LB}$ = 0.804 g/cm$^3$) for estimation of parameters:

   $$\varepsilon_A/k = 1.92\times353.5 = 678.72\text{ K},\ \sigma_A = 1.222\ (128.17/0.973)^{1/3} = 6.22\text{ Å}$$

   $$\varepsilon_B/k = 1.15\times77.4 = 89.01\text{ K},\ \sigma_B = 1.18\ (28.01/0.804)^{1/3} = 3.85\text{ Å}$$

   Note that Svehla's (Svehla, R. A., NASA Tech. Rep. R-132, Lewis Research Ctr., Cleveland, Ohio, 1962) values for air are $\varepsilon_B/k = 78.6$ K and $\sigma_B = 3.711$ Å.

   $$\varepsilon_{AB}/k=(\varepsilon_A\varepsilon_B)^{1/2}/k=(678.72\times89.01)^{1/2}=245.79\text{ K}$$

   $$\sigma_{AB}=(6.22+3.85)/2=5.04\text{ Å}$$

   $$T^*=kT/\varepsilon_{AB}=303.2/245.79=1.234$$

1. $\xi_B = 2.26$, $M_A = 73.09$ g/mol, $M_B = 18.016$ g/mol, $\mu_B = 0.6529$ cP
   $V_A = 73.09/0.9294 = 78.64$ cm$^3$/gmol
   $D_{AB} = 1.17\times10^{-13}\,(\xi_B M_B)^{1/2}\,T/(\mu_B(\varphi V_A)^{0.6}) = 1.651\times10^{-5}$ cm$^2$/s
   The experimental value is $1.65\times10^{-5}$ cm$^2$/s.

2. $H_2O$ in DMF ( following Kooijman's suggestions):
   $\xi_B = 2.6$ $M_A = 18.016$ g/mol $M_B = 73.09$ g/mol $\mu_B = 0.7143$ cP
   $\varphi V_A = 4.5\times18.016/0.9922 = 78.64$ cm$^3$/gmol
   $D_{AB} = 1.17\times10^{-13}\,(\xi_B M_B)^{1/2}\,T/(\mu_B V_A^{0.6}) = 3.185\times10^{-5}$ cm$^2$/s
   The experimental value is $2.75\times10^{-5}$ cm$^2$/s.

## MAXWELL-STEFAN ANALYSIS

Fick's law was originally developed for dilute binary diffusion based on analogy to Fourier's law, and then it was successfully extended to concentrated solutions. Although Fick's law has been extended to ternary mixtures, the resulting equations, except for a few special cases, are complex and require additional diffusivity values, some of which may be negative to fit experimental data. The Maxwell-Stefan (M-S) and Fickian analyses give identical results for binary systems, and the choice of which to use becomes one of personal preference. For multicomponent gas systems, the M-S method has clear advantages that are outlined in this section. Curtis and Bird [*Ind. Eng. Chem. Res.* **38:** 2515 (1999)] reconciled the multicomponent Fick's law approach with the more elegant M-S theory.

In the late 1800s, the development of the kinetic theory of gases led to a method developed by Maxwell and Stefan for calculating multicomponent gas diffusion (e.g., the flux of each species in a mixture). The M-S diffusion equations for $N_c$ components in a reference system moving at the average molar velocity are simpler in principle than extensions of Fick's law since they employ binary diffusivities:

$$\nabla x_i=\sum_{j=1}^{N_c}\frac{1}{c\mathscr{D}_{ij}}(x_iN_j-x_jN_i) \tag{5-238}$$

For ideal gases, the values $\mathscr{D}_{ij}$ of this equation are equal to the binary diffusivities for the $ij$ pairs, which are identical to the Fickian diffusivities,

Equation (5-238) can be solved for $N_c - 1$ independent fluxes. An additional equation (called a "bootstrap" equation) based on the movement of the reference system or the reaction stoichiometry is needed to determine all $N_c$ fluxes. For example, for equimolar counterdiffusion this expression is $\sum_{j=1}^{N_c}(N_j)=0$.

A study of ternary gas diffusion showed that the M-S equations predicted the experimental results within the experimental error [Duncan and Toor, *AIChE J.* **8:** 38 (1962)]. These predictions include a zero component flux despite the presence of that component's concentration gradient, a finite component flux with no component concentration gradient, and flux of a component in the direction opposite the component's concentration gradient. Simplified solutions for ternary diffusion of ideal gases with equimolal counterdiffusion are shown later in Examples 5-15 and 5-16.

For nonideal systems the generalized form of the driving forces is based on the derivative of the chemical potential $\mu_i$ (see Taylor and Krishna, Wesselingh and Krishna, Datta and Vilekar [*Chem. Eng. Sci.* **65:** 5976 (2010)] and Krishna and Wesselingh [*Chem. Eng. Sci.* **52:** 861 (1997)]):

$$\frac{x_i}{RT}\nabla\mu_i\big|_{T,p}=\sum_{j=1}^{N_c}\frac{1}{c\mathscr{D}_{ij}}(x_iN_j-x_jN_i) \tag{5-239}$$

For liquids activity coefficients are included in the M-S equations

$$\left(1+\frac{x_i}{\gamma_i}\frac{\partial\gamma_i}{\partial x_i}\right)\nabla x_i=\sum_{j=1}^{N_c}\frac{1}{c\mathscr{D}_{ij}}(x_iN_j-x_jN_i) \tag{5-240}$$

Although in principle extension of the M-S equations to nonideal liquid systems is straightforward, in practice the need for extensive activity coefficient data and the variability of the $\mathscr{D}_{ij}$ can prove daunting.

Almost all reported diffusivities are based on the Fickian model. The relationship between binary Fickian and M-S diffusivities is

$$\mathscr{D}_{ij} = \frac{D_{ij}}{1 + \dfrac{x_i}{\gamma_i}\dfrac{\partial \gamma_i}{\partial x_i}} \tag{5-241}$$

The Fickian and M-S binary diffusivities are equal at the infinite dilution limit and for ideal systems.

The generalized form of the M-S equations in terms of the gradient of the chemical potential can include electromagnetic effects and thermal and pressure diffusion. Since electroneutrality can be included, the M-S method may be applied to electrolyte diffusion [Kraaijeveld, Wesselingh, and Kuiken, *Ind. Eng. Chem. Res.* **33:** 750 (1994)]. Ordinary molecular diffusion and pressure and thermal diffusion in multicomponent mixtures have been studied [Ghorayeb and Firoozabadi, *AIChE J.* **46:** 883 (2000)].

Approximate solutions have been developed by linearization [Toor, H. L., *AIChE J.* **10:** 448 and 460 (1964); Stewart and Prober, *Ind. Eng. Chem. Fundam.* **3:** 224 (1964)]. Those differ in details but yield about the same accuracy as Smith and Taylor [*Ind. Eng. Chem. Fundam.* **22:** 97 (1983)]. More recently, efficient algorithms for solving the equations exactly have been developed; see Benitez, Taylor and Krishna, Krishnamurthy and Taylor [*Chem. Eng. J.* **25:** 47 (1982)] and Taylor and Webb [*Comput. Chem. Eng.* **5:** 61 (1981)]. Amundson, Pan, and Paulson [*AIChE J.* **48:** 813 (2003)] presented numerical methods for coping with mixtures having four or more components, which are nearly intractable via the analytical M-S method.

An even simpler approach than solving the M-S differential equations is to use difference equations (see Wesselingh and Krishna, and Wankat [114]). For a ternary system with mass transfer in the $z$ direction the difference equation is

$$\left(1 + \frac{\bar{x}_A}{\bar{\gamma}_A}\overline{\frac{\partial \gamma_A}{\partial x_A}}\right)\frac{\Delta x_A}{\Delta z} = -\frac{\bar{x}_B \bar{N}_{A,z} - \bar{x}_A \bar{N}_{B,z}}{\bar{c}\,\bar{\mathscr{D}}_{AB}} - \frac{\bar{x}_C \bar{N}_{A,z} - \bar{x}_A \bar{N}_{C,z}}{\bar{c}\,\bar{\mathscr{D}}_{AC}} \tag{5-242}$$

with equivalent equations for the other components. The bars indicate evaluation of the terms at the average conditions. For ideal gases this equation simplifies to

$$\bar{c}\frac{\Delta y_A}{\Delta z} = -\frac{\bar{y}_B \bar{N}_{A,z} - \bar{y}_A \bar{N}_{B,z}}{\bar{\mathscr{D}}_{AB}} - \frac{\bar{y}_C \bar{N}_{A,z} - \bar{y}_A \bar{N}_{C,z}}{\bar{\mathscr{D}}_{AC}} \tag{5-243}$$

Although difference equation solutions are approximate, they show typical multicomponent behavior. The solutions can be made more exact by including additional $\Delta z$ segments.

The M-S equations are often used for multicomponent gas mixtures because each $\mathscr{D}_{ij}$ is practically independent of composition by itself and in a multicomponent mixture. This procedure is illustrated with the difference equation formulation in Example 5-16.

***Example 5-16 Maxwell-Stefan Diffusion Without a Gradient*** Two identical large glass bulbs are filled with gases and connected by a capillary tube that is $\delta = 0.0090$ m long. Bulb 1 at $z = 0$ contains the following mole fractions: $y_{air} = 0.620$, $y_{H2} = 0.380$, and $y_{NH3} = 0.000$. Bulb 2 at $z = \delta$ contains $y_{air} = 0.620$, $y_{H2} = 0.000$, and $y_{NH3} = 0.380$. Operation is assumed to be at pseudo- (or quasi-) steady state. The pressure and temperature are uniform at 1.5 atm and 273 K, respectively. Diffusivity values at 1.0 atm and 273 K are $D_{air\text{-}H2} = 0.611$, $D_{air\text{-}NH3} = 0.198$, and $D_{H2\text{-}NH3} = 0.748$ cm$^2$/s. Assume the gases are ideal. Estimate the fluxes of the three components using the M-S difference equation formulation.

*Solution* Let $A$ = air, $B$ = hydrogen, and $C$ = ammonia. Since $Dp$ = constant, $D(1.5\text{ atm}) = D(1\text{ atm})/(1.5\text{ atm})$. At pseudo-steady state, mole fractions at the boundaries are constant (e.g., $y_{air} = 0.620$ at $z = 0$ and $y_{air} = 0.620$ at $z = \delta$ so that $\Delta y_{air} = 0.00$). Since temperature and pressure are constant and the molar densities of ideal gases are equal, the system has equimolar counterdiffusion and the total flux is zero, $N_C = -N_A - N_B$. Substitute this expression into Eq. (5-243) and the equivalent equation for $B$.

$$\frac{\bar{\rho}_m \Delta y_A}{\Delta z} = -\left(\frac{\bar{y}_B}{\bar{\mathscr{D}}_{AB}} + \frac{\bar{y}_C}{\bar{\mathscr{D}}_{AC}} + \frac{\bar{y}_A}{\bar{\mathscr{D}}_{AC}}\right)\bar{N}_A + \left(\frac{\bar{y}_A}{\bar{\mathscr{D}}_{AB}} - \frac{\bar{y}_A}{\bar{\mathscr{D}}_{AC}}\right)\bar{N}_B \tag{5-244$a$}$$

$$\frac{\bar{\rho}_m \Delta y_B}{\Delta z} = \left(\frac{\bar{y}_B}{\bar{\mathscr{D}}_{BA}} - \frac{\bar{y}_B}{\bar{\mathscr{D}}_{BC}}\right)\bar{N}_A - \left(\frac{\bar{y}_A}{\bar{\mathscr{D}}_{BA}} + \frac{\bar{y}_C}{\bar{\mathscr{D}}_{BC}} + \frac{\bar{y}_B}{\bar{\mathscr{D}}_{BC}}\right)\bar{N}_B \tag{5-244$b$}$$

Determine $N_B$ from the first equation and $N_A$ from the second.

$$\bar{N}_B = \frac{\dfrac{\bar{\rho}_m \Delta y_A}{\Delta z} + \left(\dfrac{\bar{y}_B}{\bar{\mathscr{D}}_{AB}} + \dfrac{\bar{y}_C}{\bar{\mathscr{D}}_{AC}} + \dfrac{\bar{y}_A}{\bar{\mathscr{D}}_{AC}}\right)\bar{N}_A}{\left(\dfrac{\bar{y}_A}{\bar{\mathscr{D}}_{AB}} - \dfrac{\bar{y}_A}{\bar{\mathscr{D}}_{AC}}\right)} \tag{5-245$a$}$$

$$\bar{N}_A = \frac{\dfrac{\bar{\rho}_m \Delta y_B}{\Delta z} + \left(\dfrac{\bar{y}_A}{\bar{\mathscr{D}}_{BA}} + \dfrac{\bar{y}_C}{\bar{\mathscr{D}}_{BC}} + \dfrac{\bar{y}_B}{\bar{\mathscr{D}}_{BC}}\right)\bar{N}_B}{\left(\dfrac{\bar{y}_B}{\bar{\mathscr{D}}_{BA}} - \dfrac{\bar{y}_B}{\bar{\mathscr{D}}_{BC}}\right)} \tag{5-245$b$}$$

Input these equations and the values for mole fractions at the boundaries, diffusivities, $\rho_m$ from ideal gas law, and $\Delta z = \delta$ into a spreadsheet. Guess a value for $N_{A,guess}$, calculate $N_{A,calc}$ and $N_{B,calc}$, and use Goal Seek to make $N_{A,guess} - N_{A,calc} = 0$ by changing the value of $N_{A,guess}$. Then $N_C = -(N_A + N_B)$.

*Results* $N_{air} = -5.846 \times 10^{-5}$, $N_{H2} = 1.216 \times 10^{-4}$, and $N_{NH3} = -6.312 \times 10^{-5}$ kmol/(m$^2$s). The transfer rates = $N \times$ (area of capillary tube). As expected, hydrogen diffuses in the positive direction and ammonia in the negative direction. The surprise is the substantial negative diffusion rate of air despite a Fickian driving force of zero. The air diffusion is caused by the friction of the ammonia.

***Example 5-17 Maxwell-Stefan Diffusion Counter to Gradient*** Repeat Example 5-16, but bulb 2 at $z = \delta$ contains $y_{air} = 0.610$, $y_{H2} = 0.010$, and $y_{NH3} = 0.380$.

*Solution* The solution approach is identical to that of Example 5-16, and the same spreadsheet is used with different mole fractions in bulb 2.

*Results* $N_{air} = -5.561 \times 10^{-5}$, $N_{H2} = 1.1850 \times 10^{-4}$, and $N_{NH3} = -6.289 \times 10^{-5}$ kmol/(m$^2$s). Since air and hydrogen have gradients in the same direction, extrapolation of binary Fickian diffusion would lead us to expect diffusion of these gases in the same direction. However, because of friction with ammonia, the diffusion of air is in the same direction as the ammonia.

The spreadsheet can be used for other ideal gas, ternary diffusion systems with equimolal counterdiffusion that are at either steady state or pseudo-steady state. Kmit and Shah [*Chem. Eng. Educ.* **30**(1): 14 (1996)] have a detailed discussion of when pseudo-steady state is valid.

**Multicomponent Liquid Mixtures** Most liquid mixtures are not ideal, and each $\mathscr{D}_{ij}$ can be strongly composition-dependent in binary mixtures; moreover, the binary $\mathscr{D}_{ij}$ are strongly affected in a multicomponent mixture (see Taylor and Krishna). Several theories have been developed for predicting multicomponent liquid-diffusion coefficients, but the necessity for extensive activity data, pure component and mixture volumes, mixture viscosity data, and tracer and binary diffusion coefficients has significantly limited the utility of the theories (see Poling et al.).

One particular case of multicomponent liquid diffusion that is somewhat tractable is the dilute diffusion of a solute in a homogeneous mixture (e.g., of $A$ in $B + C$). Umesi and Danner [*Ind. Eng. Chem. Process Des. Dev.* **20:** 662 (1981)] compared the three equations given below for 49 ternary systems. All three equations were equivalent, giving average absolute deviations of 25 percent.

Perkins and Geankoplis [*Chem. Eng. Sci.* **24:** 1035 (1969)] suggested the following empirical equation as an extension of the Caldwell-Babb [4] equation, in order to take into account variations in viscosity in multicomponent mixtures.

$$D_{am}\mu_m^{0.8} = \sum_{\substack{j=1 \\ j\neq A}}^{n} x_j D_{Aj}^o \mu_j^{0.8} \tag{5-246}$$

Cullinan [*Can. J. Chem. Eng.* **45:** 377 (1967)] extended Vignes' equation to multicomponent systems:

$$D_{am} = \prod_{\substack{j=1 \\ j\neq A}}^{n} \left(D_{Aj}^o\right)^{x_j} \tag{5-247}$$

Leffler and Cullinan [13] extended their binary relation to an arbitrary multicomponent mixture:

$$D_{am}\mu_m = \prod_{\substack{j=1 \\ j\neq A}}^{n} \left(D_{Aj}^o \mu_j\right)^{x_j} \tag{5-248}$$

where $D_{Aj}$ is the dilute binary diffusion coefficient of $A$ in $j$; $D_{am}$ is the dilute diffusion of $a$ through $m$; $x_j$ is the mole fraction; $\mu_j$ is the viscosity of component $j$; and $\mu_m$ is the mixture viscosity.

Dilute multicomponent diffusion of gases in aqueous electrolyte solutions is of significant practical interest because many gas absorption processes use electrolyte solutions. Akita [*Ind. Eng. Chem. Fundam.* **10:** 89 (1981)] presents experimentally tested equations for this case.

Multicomponent diffusion of electrolytes is important in ion exchange. Graham and Dranoff [*Ind. Eng. Chem. Fundam.* **21:** 360, 365 (1982)] found that the M-S interaction coefficients reduce to limiting ion tracer diffusivities of each ion. Pinto and Graham [*AIChE J.* **32:** 291 (1986) and **33:** 436 (1987)] corrected for solvation effects in multicomponent diffusion in electrolyte solutions. They achieved excellent results for 1-1 electrolytes in water at 25°C up to concentrations of 4$M$.

## DIFFUSION OF FLUIDS IN POROUS SOLIDS

Diffusion in porous solids is usually the most important factor controlling mass transfer in adsorption, ion exchange, drying, heterogeneous catalysis, leaching, and many other applications. Some of the applications of interest are outlined in Table 5-16. Applications of these equations are found in Secs. 16, 22, and 23.

Diffusion within the largest cavities of a porous medium is assumed to be similar to ordinary or bulk diffusion except that it is hindered by the pore walls [see Eq. (5-249)]. The tortuosity $\tau$ that expresses this hindrance was originally estimated from geometric arguments. Unfortunately, measured values are often an order of magnitude greater than those estimates. Thus, the effective diffusivity $D_{\text{eff}}$ (and hence $\tau$) is normally determined by comparing a diffusion model to experimental measurements. The normal range of tortuosities for silica gel, alumina, and other porous solids is $2 \le \tau \le 6$, but for activated carbon, $5 \le \tau \le 65$.

In small pores and at low pressures, the mean free path $\ell$ of the gas molecule (or atom) is significantly greater than the pore diameter $d_{\text{pore}}$. Its magnitude may be estimated from

$$\ell = \frac{3.2\mu}{P}\left(\frac{RT}{2\pi M}\right)^{1/2} \quad \text{m} \tag{5-261}$$

As a result, collisions with the wall occur more frequently than with other molecules. This is referred to as the *Knudsen mode of diffusion* and is contrasted with ordinary or bulk diffusion, which occurs by intermolecular collisions. At intermediate pressures, both ordinary diffusion and Knudsen diffusion may be important [see Eqs. (5-252) and (5-253)].

For gases and vapors that adsorb on the porous solid, surface diffusion may be important, particularly at high surface coverage [see Eqs. (5-254) and (5-257)]. The mechanism of surface diffusion may be viewed as molecules hopping from one surface site to another. Thus, if adsorption is too strong, surface diffusion is impeded, while if adsorption is too weak, surface diffusion contributes insignificantly to the overall rate. Surface diffusion and bulk diffusion usually occur in parallel [see Eqs. (5-258) and (5-259)]. Although $D_s$ is expected to be less than $D_{\text{eff}}$, the solute flux due to surface diffusion may be larger than that due to bulk diffusion if $\partial q_i/\partial z >> \partial C_i/\partial z$. This can occur when a component is strongly adsorbed and the surface coverage is high. For all that, surface diffusion is not well understood. The references in Table 5-15 should be consulted for further details. For multicomponent diffusion in porous media the M-S formulation should be employed for combinations of ordinary, Knudsen, and surface diffusion (see Krishna, *Gas Separ. Purific.* **7**(2): 91 (1993)).

## INTERPHASE MASS TRANSFER

Transfer of material between phases is important in most separation processes in which two phases are involved. In this section, mass transfer between gas and liquid phases is discussed. The principles are easily applied to other phases. When one phase is pure, mass transfer in the pure phase

**TABLE 5-16 Relations for Diffusion in Porous Solids**

| Mechanism | Equation | | Applies to | References* |
|---|---|---|---|---|
| Bulk diffusion in pores | $D_{\text{eff}} = \dfrac{\varepsilon_p D}{\tau}$ | (5-249) | Gases or liquids in large pores. $N_{Kn} = \ell/d_{\text{pore}} < 0.01$ | [24] |
| Knudsen diffusion | $D_K = 48.5\, d_{\text{pore}}\left(\dfrac{T}{M}\right)^{1/2}$ in $\text{m}^2/\text{s}$ | (5-250) | Dilute (low pressure) gases in small pores. $N_{Kn} = \ell/d_{\text{pore}} > 10$ | Geankoplis, [25, 26] |

| | $J = -D_{\text{app}}\left(\dfrac{dp_i}{dz}\right)$ | (5-259) | " " " " | |
| | $D_{\text{app}} = D_{\text{eff}} + D_{\text{Seff}}\rho_p\left(\dfrac{dq_i}{dp_i}\right)$ | (5-260) | " " " " | |

*Author names refer to the General References list at the beginning of the Mass Transfer subsection (pp. 5-41, 5-42). Bracketed numbers refer to the table reference lists (p. 5-42).

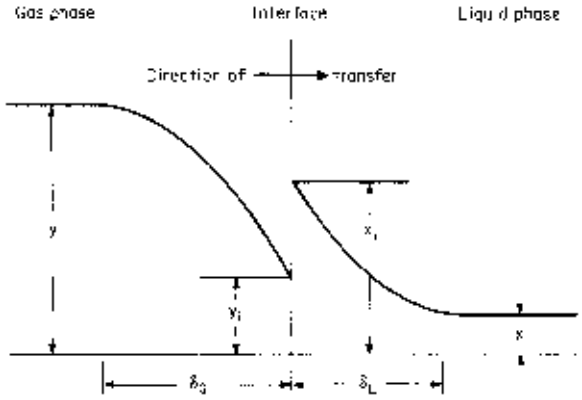

**FIG. 5-24** Concentration gradients near a gas-liquid interface.

is not involved. For example, when a pure liquid is being evaporated into a gas, only the gas-phase mass transfer need be calculated. When phases are not pure, the gas phase consists of an insoluble carrier gas plus solute *A*, and the liquid phase consists of a nonvolatile solvent plus solute *A*. Thus, mass transfer in each phase is binary. When the resistance to mass transfer is much larger in one phase than in the other, mass transfer in the phase with low resistance may be neglected even though pure components are not involved. Understanding the nature and magnitudes of these resistances is one of the keys to performing reliable mass-transfer analyses.

**Mass-Transfer Principles: Dilute Systems** When material is transferred from one phase to another across an interface that separates the two, the resistance to mass transfer in each phase causes a concentration gradient in each, as shown in Fig. 5-24 for a gas-liquid interface. The concentrations of the diffusing material in the two phases immediately adjacent to the interface generally are unequal, even if expressed in the same units, but usually are assumed to reach equilibrium almost immediately when a gas and a liquid are brought into contact.

For systems with dilute solute concentrations in the gas and liquid phases, the rate of mass transfer is proportional to the difference between the solute's bulk concentration and its concentration at the gas-liquid interface. Thus

$$N_A = k'_G(p - p_i) = k'_L(c_i - c) \tag{5-262}$$

where $N_A$ = mass-transfer rate, $k'_G$ = gas-phase mass-transfer coefficient, $k'_L$ = liquid-phase mass-transfer coefficient, $p$ = solute partial pressure in bulk gas, $p_i$ = solute partial pressure at interface, $c$ = solute concentration in bulk liquid, and $c_i$ = solute concentration in liquid at the interface. The mass-transfer coefficients $k'_G$ and $k'_L$ by definition are equal to the ratios of the molal mass flux $N_A$ to the concentration driving forces $p - p_i$ and $c_i - c$, respectively.

An alternative expression for the rate of transfer in dilute systems is given by

$$N_A = k_G(y - y_i) = k_L(x_i - x) \tag{5-263}$$

where $k_G$ = gas-phase mass-transfer coefficient, $k_L$ = liquid-phase mass-transfer coefficient, $y$ = mole-fraction solute in bulk-gas phase, $y_i$ = mole-fraction solute in gas at interface, $x$ = mole-fraction solute in bulk-liquid phase, and $x_i$ = mole-fraction solute in liquid at interface. The mass-transfer coefficients defined by Eqs. (5-262) and (5-263) are related to each other as follows:

$$k_G = k'_G p_T \tag{5-264a}$$

$$k_L = k'_L \overline{\rho}_L \tag{5-264b}$$

where $p_T$ = total system pressure employed *during the experimental determinations* of $k'_G$ values and $\overline{\rho}_L$ = average molar density of the liquid phase. The coefficient $k_G$ is relatively independent of the total system pressure and therefore is more convenient to use than $k'_G$, which is inversely proportional to the total system pressure.

The above equations may be used for finding the interfacial concentrations corresponding to any set of values of $x$ and $y$ provided the ratio of the individual coefficients is known. Thus

$$(y - y_i)/(x_i - x) = k_L/k_G = k'_L \overline{\rho}_L / k'_G p_T = L_M H_G / G_M H_L \tag{5-265}$$

where $L_M$ = molar liquid velocity, $G_M$ = molar gas velocity, $H_L$ = height of 1 transfer unit based on liquid-phase resistance, Eq. (5-283), and $H_G$ = height of 1 transfer unit based on gas-phase resistance, Eq. (5-281). The interfacial mole fractions $y_i$ and $x_i$ can be determined by solving Eq. (5-265) simultaneously with the equilibrium relation $y_i^* = F(x_i)$ to obtain $y_i$ and $x_i$. The rate of transfer may then be calculated from Eq. (5-263). Equation (5-265) may be solved graphically if a plot is made of the equilibrium vapor and liquid compositions and a point representing the bulk concentrations $x$ and $y$ is located on this diagram. This construction is shown in Fig. 5-25, which represents a gas absorption situation.

If the equilibrium relation $y_i^* = F(x_i)$ is linear, not necessarily through the origin, the rate of transfer is proportional to the difference between the bulk concentration in one phase and the concentration (in that same phase), which would be in equilibrium with the bulk concentration in the second phase. One such difference is $y - y^*$, and another is $x^* - x$. In this case, there is no need to solve for the interfacial compositions, as may be seen from the following derivation.

The rate of mass transfer may be defined by the equation

$$N_A = K_G(y - y^*) = k_G(y - y_i) = k_L(x_i - x) = K_L(x^* - x) \tag{5-266}$$

where $K_G$ = overall gas-phase mass-transfer coefficient, $K_L$ = overall liquid-phase mass-transfer coefficient, $y^*$ = vapor composition in equilibrium with $x$, and $x^*$ = liquid composition in equilibrium with vapor of composition $y$. This equation can be rearranged to the formula

$$\frac{1}{K_G} = \frac{1}{k_G}\left(\frac{y - y^*}{y - y_i}\right) = \frac{1}{k_G} + \frac{1}{k_G}\left(\frac{y_i - y^*}{y - y_i}\right) = \frac{1}{k_G} + \frac{1}{k_L}\left(\frac{y_i - y^*}{x_i - x}\right) \tag{5-267}$$

in view of Eq. (5-265). Comparison of the last term in parentheses with the diagram of Fig. 5-25 shows that it is equal to the slope of the chord connecting the points $(x, y^*)$ and $(x_i, y_i)$. If the equilibrium curve is a straight line, then this term is the slope $m$. Thus

$$1/K_G = 1/k_G + m/k_L \tag{5-268}$$

When Henry's law is valid ($p_A = Hx_A$ or $p_A = H'C_A$), the slope $m$ is

$$m = H/p_T = H' \overline{\rho}_L / p_T \tag{5-269}$$

where $m$ is defined in terms of mole-fraction driving forces in Eq. (5-263).

If it is desired to calculate the rate of transfer from the overall concentration difference based on bulk-liquid compositions $x^* - x$, the appropriate overall coefficient $K_L$ is related to the individual coefficients by the equation

$$1/K_L = 1/k_L + 1/(mk_G) \tag{5-270}$$

Conversion of these equations to a $k'_G$, $k'_L$ basis can be accomplished readily by direct substitution of Eqs. (5-264*a*) and (5-264*b*).

Occasionally one will find $k'_L$ or $K'_L$ values reported in units (SI) of meters per second. The correct units for these values are kmol/[(s · m²)(kmol/m³)],

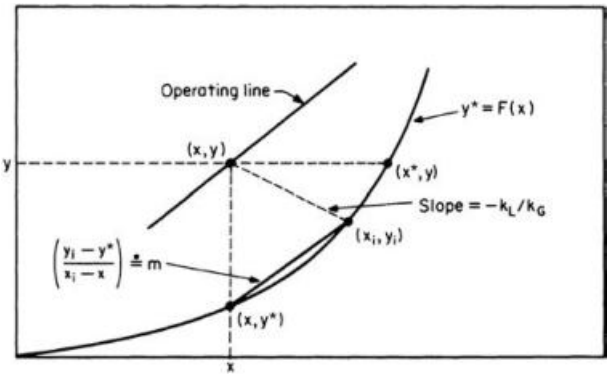

**FIG. 5-25** Identification of concentrations at a point in a countercurrent absorption tower.

and Eq. (5-264*b*) is the correct equation for converting them to a mole-fraction basis.

When $k'_G$ and $K'_G$ values are reported in units (SI) of kmol/[(s · m²)(kPa)], one must be careful, in converting them to a mole-fraction basis, to multiply by the total pressure actually employed in the original experiments and *not* by the total pressure of the system to be designed. This conversion is valid for systems in which Dalton's law of partial pressures ($p = yp_T$) is valid.

Comparison of Eqs. (5-268) and (5-270) shows that for systems in which the equilibrium line is straight, the overall mass-transfer coefficients are related to one another by the equation

$$K_L = mK_G \tag{5-271}$$

When the equilibrium curve is not straight, there is no strictly logical basis for the use of an overall transfer coefficient, since the value of $m$ will be a function of position in the apparatus, as can be seen from Fig. 5-25. In such cases the rate of transfer should be calculated by solving for the interfacial compositions as described above. Experimentally observed rates of mass transfer often are expressed in terms of overall transfer coefficients even when the equilibrium lines are curved. This procedure is approximate, since the rates of transfer may not vary in direct proportion to the overall bulk concentration differences $y - y^*$ and $x^* - x$ at all concentration levels even though the rates may be proportional to the concentration difference in each phase taken separately, that is, $x_i - x$ and $y - y_i$.

In most types of separation equipment such as packed or spray towers, the interfacial area that is effective for mass transfer cannot be accurately determined. For this reason it is customary to report experimentally observed rates of transfer in terms of transfer coefficients based on a unit volume of the apparatus rather than on a unit of interfacial area. Such volumetric coefficients are designated as $K_G a$, $k_L a$, etc., where $a$ represents the interfacial area per unit volume of the apparatus. Experimentally observed variations in the values of these volumetric coefficients with variations in flow rates, type of packing, etc., may be due as much to changes in the effective value of $a$ as to changes in $k$. Calculation of the overall coefficients from the individual volumetric coefficients is done by means of the equations

$$1/(K_G a) = 1/(k_G a) + m/(k_L a) \tag{5-272a}$$

$$1/(K_L a) = 1/(k_L a) + 1/(mk_G a) \tag{5-272b}$$

Because of the wide variation in equilibrium, the variation in the values of $m$ from one system to another can have an important effect on the overall coefficient and on the selection of the type of equipment to use. For example, if $m$ is large, the liquid-phase part of the overall resistance might be extremely large where $k_L$ might be relatively small. This kind of reasoning must be applied with caution, however, since species with different equilibrium characteristics are separated under different operating conditions. Thus, the effect of changes in $m$ on the overall resistance to mass transfer may partly be counterbalanced by changes in the individual specific resistances as the flow rates are changed.

**Mass-Transfer Principles: Concentrated Systems** When solute concentrations in the gas and/or liquid phases are large, the equations derived above for dilute systems no longer are applicable. The correct equations to use for concentrated systems are as follows:

$$N_A = \hat{k}_G (y - y_i)/y_{BM} = \hat{k}_L (x_i - x)/x_{BM}$$
$$= \hat{K}_G (y - y^*)/y^*_{BM} = \hat{k}_L (x^* - x)/x^*_{BM} \tag{5-273}$$

where $N_B = 0$. In these and following equations, $y_B$ represents the insoluble carrier gas in the gas phase and $x_B$ represents the nonvolatile solvent in the liquid. Hence, $y_A = y$ and $x_A = x$ represent the solute in the gas and liquid phases, respectively. Thus, for example, it is understood that $1 - x = x_B$.

$$y_{BM} = \frac{(1-y)-(1-y_i)}{\ln\left[(1-y)/(1-y_i)\right]} \tag{5-274a}$$

$$y^*_{BM} = \frac{(1-y)-(1-y^*)}{\ln[(1-y)/(1-y^*)]} \tag{5-274b}$$

$$x_{BM} = \frac{(1-x)-(1-x_i)}{\ln[(1-x)/(1-x_i)]} \tag{5-275a}$$

$$x^*_{BM} = \frac{(1-x)-(1-x^*)}{\ln[(1-x)/(1-x^*)]} \tag{5-275b}$$

For concentrated systems the gas-phase $\hat{k}_G$ and liquid-phase $\hat{k}_L$ mass-transfer coefficients and the overall gas-phase $\hat{K}_G$ and liquid-phase $\hat{K}_L$ mass-transfer coefficients are defined later in Eqs. (5-278) to (5-280).

The factors $y_{BM}$ and $x_{BM}$ arise because in the diffusion of a solute through a stationary layer of fluid the resistance to diffusion varies in proportion to the concentration of the stationary fluid, approaching zero as the concentration of the fluid approaches zero. See Eq. (5-198).

The factors $y^*_{BM}$ and $x^*_{BM}$ cannot be justified on the basis of mass-transfer theory since they are based on overall resistances. These factors therefore are included in the equations by analogy with the corresponding film equations.

In dilute systems the logarithmic-mean insoluble-gas and nonvolatile-liquid concentrations approach unity, and Eq. (5-273) reduces to the dilute system formula, Eq. (5-266). For equimolar counterdiffusion (e.g., binary distillation), the log-mean factors are omitted. See Eq. (5-197).

Substitution of Eqs. (5-274) and (5-275) into Eq. (5-273) results in the following simplified formula:

$$N_A = \hat{k}_G \ln[(1-y_i)/(1-y)] = \hat{K}_G \ln[(1-y^*)/(1-y)] = \hat{k}_L \ln[(1-x)/(1-x_i)]$$
$$= \hat{K}_L \ln[(1-x)/(1-x^*)] \tag{5-276}$$

Note that the units of $\hat{k}_G$, $\hat{K}_G$, $\hat{k}_L$, and $\hat{K}_L$ are identical, i.e., kmol/(s · m²) in SI units.

The interfacial gas and liquid compositions in concentrated systems can be determined from

$$(y - y_i)/(x_i - x) = \hat{k}_L y_{BM}/\hat{k}_G x_{BM}$$
$$= L_M H_G y_{BM}/G_M H_L x_{BM} = k_L/k_G \tag{5-277}$$

This equation is identical to Eq. (5-265) for dilute systems since $\hat{k}_G = k_G y_{BM}$ and $\hat{k}_L = k_L x_{BM}$, and $y_{BM}$ and $x_{BM}$ are both 1 in dilute systems. Note, however, that when $\hat{k}_G$ and $\hat{k}_L$ are given, the equation must be solved by trial and error, since $x_{BM}$ contains $x_i$ and $y_{BM}$ contains $y_i$.

The overall gas-phase and liquid-phase mass-transfer coefficients for concentrated systems are computed from

$$\frac{1}{\hat{K}_G} = \frac{y_{BM}}{y^*_{BM}}\frac{1}{\hat{k}_G} + \frac{x_{BM}}{y^*_{BM}}\frac{1}{\hat{k}_L}\left(\frac{y_i - y^*}{x_i - x}\right) \tag{5-278}$$

$$\frac{1}{\hat{K}_L} = \frac{x_{BM}}{x^*_{BM}}\frac{1}{\hat{k}_L} + \frac{y_{BM}}{x^*_{BM}}\frac{1}{\hat{k}_G}\left(\frac{x^* - x_i}{y - y_i}\right) \tag{5-279}$$

When the equilibrium curve is a straight line, the terms in parentheses can be replaced by the slope $m$ or $1/m$ as before. In this case, the overall mass-transfer coefficients for concentrated systems are related to one another by the equation

$$\hat{K}_L = m\hat{K}_G\left(x^*_{BM}/y^*_{BM}\right) \tag{5-280}$$

All these equations reduce to their dilute system equivalents as the inert concentrations approach unity in terms of mole fractions of inert concentrations in the fluids.

**Height Equivalent to 1 Transfer Unit (HTU)** In packed beds used for distillation, absorption, stripping, and extraction, it is convenient to represent mass transfer as the height of apparatus required to accomplish a separation of standard difficulty. The gas-phase HTU is the ratio of gas flow rate to gas-phase mass-transfer coefficient, and the liquid-phase HTU is the ratio of the liquid flow rate to liquid-phase coefficient. The following relations between the transfer coefficients and the values of HTU apply:

$$H_G = G_M/(k_G a\, y_{BM}) = G_M/(\hat{k}_G\, a) \tag{5-281}$$

$$H_{OG} = G_M/(K_G a\, y^*_{BM}) = G_M/(\hat{K}_G\, a) \tag{5-282}$$

$$H_L = L_M/(k_L a\, x_{BM}) = L_M/(\hat{k}_L\, a) \tag{5-283}$$

$$H_{OL} = L_M/(K_L a\, x^*_{BM}) = L_M/(\hat{K}_L\, a) \tag{5-284}$$

Frequently the HTU values are closer to constant than the mass-transfer coefficients.

The equations that express the addition of individual resistances in terms of HTUs, applicable to either dilute or concentrated systems, are

$$H_{OG} = \frac{y_{BM}}{y^*_{BM}} H_G + \frac{mG_M}{L_M}\frac{x_{BM}}{y^*_{BM}} H_L \tag{5-285}$$

$$H_{OL} = \frac{x_{BM}}{x^*_{BM}} H_L + \frac{L_M}{mG_M}\frac{y_{BM}}{x^*_{BM}} H_G \tag{5-286}$$

These equations are strictly valid only when the slope $m$ of the equilibrium curve is constant, as noted previously.

***Example 5-18 Conversion of Overall Mass Transfer Coefficient*** An overall mass-transfer coefficient was experimentally measured for $SO_2$ in water at 30°C and 1 atm, and it was found to be $K'_G = 0.40$ kmol/(h · m² · atm). Linear regression of the equilibrium data in Table 2-13 yielded $y = 43.727x - 0.0081$, $R^2 = 0.9971$. Based on 30 percent of the resistance to mass transfer residing in the liquid phase, find the value of the alternative, overall mass-transfer coefficient in the liquid phase $K_L$.

*Solution* $K'_G = 0.4$ kmol/(h · m² · atm) and $P = 1.0$ atm, $K_G = PK'_G = 0.4$ kmol/(h · m²). Since resistance $= 1/K_G$, $m/k_L = 0.3/K_G \rightarrow 1/k_L = 0.3/(K_G m)$. From the equilibrium data, $m = 43.727$ (slope of $y$ versus $x$). Thus, $1/k_L = 0.3/[(0.40)(43.727)] = 0.01715$.

Similarly, $1/k_G = 0.7/K_G \rightarrow k_G = 1/1.75 = 0.5714$.

Then $1/K_L = 1/(mk_G) + 1/k_L = 1/(43.727)(0.5714) + 0.01715 = 0.0572$ and $K_L = 17.49$.

Note that $K_L = mK_G = 17.49$ kmol/(h · m²).

**Number of Transfer Units (NTU)** The total height of packing is HTU × NTU. The NTU required for a given separation is closely related to the number of theoretical stages or plates required to carry out the same separation in a stage or plate-type apparatus. For equimolal counterdiffusion, such as in a binary distillation, the number of overall gas-phase transfer units $N_{OG}$ required for changing the composition of the vapor stream from $y_1$ to $y_2$ is

$$N_{OG} = \int_{y2}^{y1} \frac{dy}{y - y^*} \tag{5-287}$$

When diffusion is in one direction only, as in the absorption of a soluble component from an insoluble gas,

$$N_{OG} = \int_{y2}^{y1} \frac{y^*_{BM}\,dy}{(1-y)(y-y^*)} \tag{5-288}$$

For dilute systems Eq. (5-288) simplifies to Eq. (5-287).

If $H_{OG}$ is constant, the total height of packing required is

$$h_T = H_{OG} N_{OG} \tag{5-289}$$

When it is known that $H_{OG}$ varies appreciably within the tower, this term must be placed inside the integral in Eqs. (5-287) and (5-288) for accurate calculations of $h_T$. For example, the packed-tower design equation in terms of the overall gas-phase mass-transfer coefficient for absorption would be expressed as follows:

$$h_T = \int_{y2}^{y1} \left[\frac{G_M}{K_G a y^*_{BM}}\right] \frac{y^*_{BM}\,dy}{(1-y)(y-y^*)} \tag{5-290}$$

where the first term under the integral can be recognized as the HTU term. Convenient solutions of these equations for special cases are discussed later.

**Film, Penetration, and Surface-Renewal Theories** In certain simple situations, the mass-transfer coefficients can be calculated from first principles. The film, penetration, and surface-renewal theories are attempts to extend these theoretical calculations to more-complex situations. Although these theories are often not accurate, they provide useful physical pictures for variations in the mass-transfer coefficient.

For the special case of steady-state unidirectional diffusion of a component through an inert-gas film in an ideal-gas system, the rate of mass transfer is derived as

$$N_A = \frac{D_{AB} p_T}{RT\delta_G}\frac{y - y_i}{y_{BM}} = \frac{D_{AB} p_T}{RT\delta_G} \ln \frac{1-y_i}{1-y} \tag{5-291}$$

where $\delta_G$ = the "effective" thickness of a stagnant-gas layer which would offer a resistance to molecular diffusion equal to the experimentally observed resistance and $R$ = the gas constant [Nernst, *Z. Phys. Chem.* **47:** 52 (1904); Whitman, *Chem. Mat. Eng.* **29:** 149 (1923), and Lewis and Whitman, *Ind. Eng. Chem.* **16:** 1215 (1924)].

According to this analysis, one can see that for gas absorption problems, which often exhibit unidirectional diffusion, the most appropriate driving-force expression is of the form $(y - y_i)/y_{BM}$, and the most appropriate mass-transfer coefficient is therefore $\hat{k}_G$. This concept recurs for all unidirectional diffusion problems. Comparing Eq. (5-273), $N_A = \hat{k}_G (y - y_i)/y_{BM}$, to Eq. (5-291), we obtain

$$\hat{k}_G = \frac{D_{AB} p_T}{RT\delta_G} = \frac{D_{AB} C}{\delta_G} \tag{5-292}$$

where C is the molar concentration of the stagnant gas film. Thus, with the film model the mass-transfer coefficient is inversely proportional to film thickness $\delta_G$, which depends primarily on the hydrodynamics of the system and hence on the Reynolds ($N_{Re}$) and Schmidt ($N_{Sc}$) numbers. Thus, the gas-phase mass-transfer coefficient $\hat{k}_G$ depends principally upon the transport properties of the fluid ($N_{Sc}$) and the hydrodynamics of the particular system involved ($N_{Re}$). Correlations have been developed for different geometries in terms of the following dimensionless variables:

$$N_{Sh} = \hat{k}_G\, RTd/(p_T D_{AB}) = \hat{k}_G\, d/(CD_{AB}) = f(N_{Re}, N_{Sc}) \tag{5-293}$$

where the Sherwood number $N_{Sh}$ and Reynolds number $N_{Re} = Gd/\mu_G$ are based on the characteristic length $d$ appropriate to the geometry of the particular system; and $N_{Sc} = \mu_G/(\rho_G D_{AB})$ is the Schmidt number.

It is sometimes convenient to work in terms of the Stanton number $N_{St} = \hat{k}_G/G_M = k'_G p_{BM} y_{BM}/G_M$, instead of the Sherwood number. The Sherwood number can be written as

$$N_{Sh} = (\hat{k}_G/G_M) N_{Re} N_{Sc} = N_{St} N_{Re} N_{Sc} \tag{5-294}$$

Equations (5-293) and (5-294) can now be combined in the alternative functional form

$$N_{St} = \hat{k}_G/G_M = g(N_{Re}, N_{Sc}) \tag{5-295}$$

It is important to recognize that specific mass-transfer correlations can be derived only in conjunction with the investigator's particular assumptions concerning the numerical values of the effective interfacial area $a$ of the packing.

The stagnant-film model assumes a steady state in which the local flux across each element of area is constant; i.e., there is no accumulation of the diffusing species within the film. For a liquid the film model predicts $\hat{k}_L = D_L C/\delta_L$. Higbie [*Trans. Am. Inst. Chem. Eng.* **31:** 365 (1935)] pointed out that industrial contactors often operate with repeated brief contacts between phases in which the contact times are too short for the steady state to be achieved. Higbie advanced the penetration theory that in a packed tower the liquid flows across each packing piece in laminar flow and is remixed at the points of discontinuity between the packing elements. Thus, a fresh liquid surface is formed at the top of each piece, and as it moves downward, it absorbs gas at a decreasing rate until it is mixed at the next discontinuity. If the velocity of the flowing stream is uniform over a very deep region of liquid (total thickness $\delta_T >> \sqrt{Dt}$), where the time-averaged liquid-phase mass-transfer coefficient $\hat{k}_L$ according to penetration theory is

$$\hat{k}_L = 2\,\overline{\rho}_L x_{BM} \sqrt{D_L/(\pi t)} \tag{5-296}$$

where $D_L$ = liquid-phase diffusion coefficient and $t$ = contact time. In practice, the contact time $t$ is not known except in special cases in which the hydrodynamics are clearly defined. This is somewhat similar to the case of the stagnant-film theory in which the unknown quantity is the thickness of the stagnant layer $\delta$.

Penetration theory predicts that $\hat{k}_L$ should vary by the square root of the molecular diffusivity, as compared with film theory, which predicts a first-power dependency on $D$. Various investigators have reported experimental powers of $D$ ranging from 0.5 to 0.75, and the Chilton-Colburn analogy uses a ⅔ power.

Penetration theory often is used in analyzing absorption with chemical reaction because it makes no assumption about the depths of penetration of the various reacting species, and it gives a more accurate result when the diffusion coefficients of the reacting species are not equal. When the reaction process is very complex, however, penetration theory is more difficult to use than film theory, and the latter method normally is preferred.

Danckwerts [*Ind. Eng. Chem.* **42:** 1460 (1951)] proposed an extension of the penetration theory, called the *surface renewal theory*, which allows for the eddy motion in the liquid to bring masses of fresh liquid continually from the interior to the surface, where they are exposed to the gas for finite lengths of time before being replaced. Danckwerts assumed that every element of fluid has an equal chance of being replaced regardless of its age. The Danckwerts model gives

$$\hat{k}_L = \overline{\rho}_L x_{BM} \sqrt{D_L s} \tag{5-297}$$

where $s$ = fractional rate of surface renewal. Both the penetration and the surface renewal theories predict a square-root dependency on $D_L$. Unfortunately, values of the surface renewal rate $s$ generally are not available, which presents the same problems as do $\delta$ and $t$ in the film and penetration models.

The predictions of correlations based on the film model often are nearly identical to predictions based on the penetration and surface renewal models. Thus, in view of its relative simplicity, the film model normally is preferred for purposes of discussion or calculation. Theoretical models have not proved adequate for making a priori predictions of mass-transfer rates in packed towers, and therefore empirical correlations such as those outlined later in Table 5-23 must be employed.

**Effects of High Solute Concentrations on $\hat{k}_G$ and $\hat{k}_L$** The stagnant-film model indicates that $\hat{k}_G$ should be independent of $y_{BM}$ and $k_G$ should be inversely proportional to $y_{BM}$. The data of Vivian and Behrman [*Am. Inst. Chem. Eng. J.* **11:** 656 (1965)] for the absorption of ammonia from an inert gas strongly suggest that the film model's predicted trend is correct. This is another indication that the most appropriate rate coefficient to use in concentrated systems is $\hat{k}_G$ and the proper driving-force term is of the form $(y - y_i)/y_{BM}$.

The use of the rate coefficient $\hat{k}_L$ and the driving force $(x_i - x)/x_{BM}$ is also believed to be appropriate. For many practical absorption and stripping situations, the liquid-phase solute concentrations are low, thus making this assumption unimportant.

**Effects of Total Pressure on $\hat{k}_G$ and $\hat{k}_L$** The influence of total system pressure on the rate of mass transfer from a gas to a liquid or to a solid has been shown to be the same as would be predicted from stagnant-film theory value of $\hat{k}_G = D_{AB}p_T/(RT\delta_G)$. Since the quantity $D_{AB}p_T$ is known to be relatively independent of the pressure, it follows that the rate coefficients $\hat{k}_G$, $k_G y_{BM}$, and $k'_G p_T y_{BM}$ $(= k'_G p_{BM})$ do not depend on the total pressure of the system, subject to the limitations discussed later.

Investigators of tower packings normally report $k'_G a$ values measured at very low inlet-gas concentrations, so that $y_{BM} = 1$, and at total pressures close to 100 kPa (~1 atm). Thus, the correct rate coefficient for use in packed-tower designs involving the use of the driving force $(y - y_i)/y_{BM}$ is obtained by multiplying the reported $k'_G a$ values by the value of $p_T$ employed in the actual test unit ( for example, 100 kPa) and *not* the total pressure of the system to be designed. In other words, one can determine $k'_G a$ in kmol/[(s · m$^3$)(kPa)] for design pressure $p_T$ (in kPa) from

$$k'_G a \text{ at design pressure } p_T = k'_G a \text{ at 1 atm} \times 101.3/p_T \tag{5-298}$$

One way to avoid a lot of confusion on this point is to convert the experimentally measured $k'_G a$ values to values of $\hat{k}_G a$ straightaway, before beginning the design calculations. A design based on the rate coefficient $\hat{k}_G a$ and the driving force $(y - y_i)/y_{BM}$ will be independent of the total system pressure with cautions for systems that have significant vapor-phase nonideality, that operate in the vicinity of the critical point, or that have total pressures higher than about 3040 to 4050 kPa (30 to 40 atm).

Experimental confirmations of the relative independence of $\hat{k}_G$ with respect to total pressure have been widely reported. Deviations do occur at extreme conditions. For example, Bretsznajder (*Prediction of Transport and Other Physical Properties of Fluids*, Pergamon Press, Oxford, 1971, p. 343) discusses the effects of pressure on the $D_{AB}p_T$ product and presents experimental data on the self-diffusion of $CO_2$ which show that the $Dp$ product begins to decrease at a pressure of approximately 8100 kPa (80 atm). For reduced temperatures ($T_r$) higher than about 1.5, the deviations are relatively modest for pressures up to the critical pressure. However, deviations are large near the critical point. The effect of pressure on the gas-phase viscosity also is negligible for pressures below about 5060 kPa (50 atm).

For the liquid-phase mass-transfer coefficient $\hat{k}_L$, the effects of total system pressure can be ignored for all practical purposes. Thus, when $\hat{k}_G$ and $\hat{k}_L$ are used for the design of gas absorbers or strippers, the primary pressure effects to consider will be those that affect the equilibrium curves and the values of $m$. However, if pressure changes affect the hydrodynamics, $\hat{k}_G$, $\hat{k}_L$, and $a$ can all change significantly.

**Effects of Temperature on $\hat{k}_G$ and $\hat{k}_L$** The Stanton number relationship for gas-phase mass transfer in packed beds, Eq. (5-295), indicates that for a given system geometry the rate coefficient $\hat{k}_G$ depends on only the Reynolds number and the Schmidt number. Since the Schmidt number for a gas is approximately independent of temperature, the principal effect of temperature upon $\hat{k}_G$ arises from changes in the gas viscosity with changes in temperature. For normally encountered temperature ranges, these effects will be small owing to the fractional powers involved in Reynolds number terms (see Tables 5-16 to 5-23). Thus, for all practical purposes $\hat{k}_G$ is independent of temperature and pressure in the normal ranges of these variables.

For modest changes in temperature, the influence of temperature upon the interfacial area $a$ may be neglected. For example, in experiments on the absorption of $SO_2$ in water, Whitney and Vivian [*Chem. Eng. Prog.* **45:** 323 (1949)] found no appreciable effect of temperature upon $\hat{k}_G a$ over the range from 10 to 50°C.

Whitney and Vivian found that the effect of temperature upon $\hat{k}_L a$ and Sherwood and Holloway [101] (see Table 5-23A) found that the effect of temperature upon $H_L$ could be explained entirely by variations in the liquid-phase viscosity and diffusion coefficient with temperature. These effects can be very large and therefore must be carefully accounted for when using $\hat{k}_L$ or $H_L$ data. For liquids, the mass-transfer coefficient $\hat{k}_L$ is correlated by Eqs. (5-297) and (5-299). Typically, the general form of the correlation for $H_L$ is (see Table 5-23)

$$H_L = bN_{\text{Re}}^{a} N_{\text{Sc}}^{1/2} \tag{5-299}$$

where $b$ is a proportionality constant and the exponent $a$ may range from about 0.2 to 0.5 for different packings and systems. The liquid-phase diffusion coefficients may be corrected from a base temperature $T_1$ to another temperature $T_2$ by using the Einstein relation as recommended by Wilke [*Chem. Eng. Prog.* **45:** 218 (1949)]:

$$D_2 = D_1(T_2/T_1)(\mu_1/\mu_2) \tag{5-300}$$

The Einstein relation can be rearranged to relate Schmidt numbers at two temperatures:

$$N_{\text{Sc2}} = N_{\text{Sc1}}(T_1/T_2)(\rho_1/\rho_2)(\mu_2/\mu_1)^2 \tag{5-301}$$

Substitution of this relation into Eq. (5-299) shows that for a given geometry the effect of temperature on $H_L$ can be estimated as

$$H_{L2} = H_{L1}(T_1/T_2)^{1/2}(\rho_1/\rho_2)^{1/2}(\mu_2/\mu_1)^{1-a} \tag{5-302}$$

In using these relations, note that for equal liquid flow rates

$$H_{L2}/H_{L1} = (\hat{k}_L a)_1/(\hat{k}_L a)_2 \tag{5-303}$$

**Maxwell-Stefan Mass Transfer** Equation (5-262) can be obtained by solving Fick's law for a thin stagnant film and then noting $\hat{k}_L = D_L C/\delta_L$ where $\delta$ is the unknown film thickness. Thus, the usual linear driving-force mass-transfer analysis is inherently a Fickian analysis that is excellent for binary mass transfer but can be problematic for multicomponent systems (see Taylor and Krishna). A M-S mass-transfer analysis can be derived by starting with Eq. (5-240), multiplying both sides of the equation by $\delta$, and defining the M-S mass-transfer coefficient as $\hat{k} = \mathcal{D}C/\delta$ (see Wesselingh and Krishna). For ternary mass transfer in the $z$ direction the result is

$$\left(1 + \frac{x_A}{\gamma_A}\frac{\partial \gamma_A}{\partial x_A}\right)\frac{dx_A}{d(z/\delta)} = -\frac{x_B N_{A,z} - x_A N_{B,z}}{\hat{k}_{AB}} - \frac{x_C N_{A,z} - x_A N_{C,z}}{\hat{k}_{AC}} \tag{5-304}$$

For ideal gases this result simplifies to

$$\frac{dx_A}{d(z/\delta)} = -\frac{y_B N_{A,z} - y_A N_{B,z}}{\hat{k}_{AB}} - \frac{y_C N_{A,z} - y_A NC,z}{\hat{k}_{AC}} \tag{5-305}$$

The resulting difference form of the mass-transfer equation for ideal ternary gas systems is

$$\Delta y_A = -\frac{\overline{y}_B \overline{N}_{A,z} - \overline{y}_A \overline{N}_{B,z}}{\overline{\hat{k}}_{AB}} - \frac{\overline{y}_C \overline{N}_{A,z} - \overline{y}_A \overline{N}_{C,z}}{\overline{\hat{k}}_{AC}} \tag{5-306}$$

For binary systems the M-S mass-transfer coefficient is related to the Fickian mass-transfer coefficient by

$$\hat{k}_{AB} = \frac{k_{AB}\mathcal{D}_{AB}}{D_{AB}} = \frac{k_{AB}}{1 + \dfrac{x_A}{\gamma_A}\dfrac{\partial \gamma_A}{\partial x_A}} \tag{5-307}$$

For ideal systems and at the infinite dilution limits $\mathcal{D}_{AB} = D_{AB}$ and $\hat{k}_{AB} = k_{AB}$. Thus, for most gas systems and for dilute liquid systems, the standard mass-transfer correlations discussed next can be used to determine $\hat{k}_{AB}$ which is then used in Eq. (5-305) or (5-306).

## MASS-TRANSFER CORRELATIONS

Because of the tremendous importance of mass transfer in chemical engineering, a very large number of studies have determined mass-transfer coefficients. Tables 5-17 to 5-24 summarize a variety of different configurations to provide a sense of the range of correlations available. These

**TABLE 5-17 Mass-Transfer Correlations for a Single Flat Plate or Disk—Transfer to or from Plate to Fluid**

| Situation | Correlation | Comments E = Empirical, S = Semiempirical, T = Theoretical | References* |
|---|---|---|---|
| A. Laminar, local, flat plate, forced flow | $N_{Sh,x} = \dfrac{k'x}{D} = 0.323\,(N_{Re,x})^{1/2}(N_{Sc})^{1/3}$<br>Coefficient 0.332 is a better fit. | [T] Low MT rates. Low mass-flux, constant property systems. $N_{Sh,x}$ is local $k$. Use with arithmetic difference in concentration. Coefficient 0.323 is Blasius' approximate solution.<br>$N_{Re,x} = \dfrac{xu_\infty\rho}{\mu}$, $x$ = length along plate | [57] p. 183<br>[66] p. 526<br>Sherwood, Pigford, & Wilke, p. 79 |
| Laminar, average, flat plate, forced flow | $N_{Sh,avg} = \dfrac{k'_m L}{D} = 0.646(N_{Re,L})^{1/2}(N_{Sc})^{1/3}$<br>Coefficient 0.664 is a better fit.<br>$k'_m$ is mean mass-transfer coefficient for dilute systems. | $N_{Re,L} = \dfrac{Lu_\infty\rho}{\mu}$ 0.664 (Polhausen)<br>is a better fit for $N_{Sc} > 0.6$, $N_{Re,x} < 3\times10^5$ | Skelland, p. 110<br>[69] p. 480 |
| $j$ factors | $j_D = j_H = \dfrac{f}{2} = 0.664(N_{Re,L})^{-1/2}$ | [S] Chilton-Colburn analogy. $N_{Sc} = 1.0$, $f$ = drag coefficient. $j_D$ is defined in terms of $k'_m$. | Skelland, p. 271 |
| B. Laminar, local, flat plate, natural convection vertical plate | $N_{Sh,x} = \dfrac{k'x}{D} = 0.508\ N_{Sc}^{1/2}(0.952+N_{Sc})^{-1/4}N_{Gr}^{1/4}$<br>$N_{Gr} = \dfrac{gx^3}{(\mu/\rho)^2}\left(\dfrac{\rho_\infty}{\rho_0}-1\right)$ | [T] Low MT rates. Dilute systems, $\Delta\rho/\rho << 1$. $N_{Gr}N_{Sc} < 10^8$. Use with arithmetic concentration difference. $x$ = length from plate bottom. | Skelland, p. 120 |
| C. Laminar, stationary disk | $N_{Sh} = \dfrac{k'd_{disk}}{D} = \dfrac{8}{\pi}$ | [T] Stagnant fluid. Use arithmetic concentration difference. | Sherwood, Pigford, & Wilke, p. 240 |
| Laminar, spinning disk | $N_{Sh} = \dfrac{k'd_{disk}}{D} = 0.879\,N_{Re}^{1/2}N_{Sc}^{1/3}$<br>$N_{Re} <\sim 10^4$ | [T] Asymptotic solution for large $N_{Sc}$. $u = \omega d_{disk}/2$, $\omega$ = rotational speed, rad/s. Rotating disks are often used in electrochemical research. | [76] p. 60<br>Sherwood, Pigford, & Wilke, p. 240 |
| D. Laminar, inclined, plate | $N_{Sh,avg} = 0.783\,N_{Re,film}^{1/9}N_{Sc}^{1/3}\left(\dfrac{x^3\rho^2 g\sin\alpha}{\mu^2}\right)^{2/9}$<br>$N_{Re,film} = \dfrac{4Q\rho}{\mu^2} < 2000$<br>$N_{Sh,avg} = \dfrac{k'_m x}{D}$<br>$\delta_{film} = \left(\dfrac{3\mu Q}{w\rho g\sin\alpha}\right)^{1/3}$ = film thickness | [T] Constant-property liquid film with low mass-transfer rates. Use arithmetic concentration difference. Newtonian fluid. Solute does not penetrate past region of linear velocity profile. Differences between theory and experiment.<br>$w$ = width of plate, $\delta_f$ = film thickness<br>$\alpha$ = angle of inclination $x$ = distance from start soluble surface. | Skelland, p. 130<br>Sherwood, Pigford, & Wilke, p. 209 |
| E. Laminar and turbulent, flat plate, forced flow | $j_D = j_H = \dfrac{f}{2} = 0.037N_{Re,L}^{-0.2}$<br>$j_D = (k_G/G_M)N_{Sc}^{2/3}$<br>$j_H = (h'/C_pG)N_{Pr}^{2/3}$ | [E] Chilton-Colburn analogies, $N_{Sc} = 1.0$, (gases), $f$ = drag coefficient. $8000 < N_{Re} < 300{,}000$. Can apply analogy, $j_D = f/2$, to entire plate (including laminar portion) if average values are used. | [57] p. 193<br>Kirwan, p. 112<br>Sherwood, Pigford, & Wilke, p. 201<br>Skelland, p. 271<br>[59] [53] |
| F. Laminar and turbulent, flat plate, forced flow | $N_{Sh,avg} = 0.037\,N_{Sc}^{1/3}(N_{Re,L}^{0.8}-15{,}500)$ to $N_{Re,L} = 320{,}000$<br>$N_{Sh,avg} = 0.037\,N_{Sc}^{1/3}\times\left(N_{Re,L}^{0.8}-N_{Re,Cr}^{0.8}+\dfrac{0.664}{0.037}N_{Re,Cr}^{1/2}\right)$<br>in range $3\times10^5$ to $3\times10^6$ | [E] Use arithmetic concentration difference.<br>$N_{Sh,avg} = \dfrac{k'_m L}{D}$, $N_{Sc} > 0.5$<br>Entrance effects are ignored. $N_{Re,Cr}$ is transition laminar to turbulent. | Kirwan, p. 112<br>Sherwood, Pigford, & Wilke, p. 201 |
| G. Turbulent, local flat plate, natural convection, vertical plate<br>Turbulent, average, flat plate, natural convection, vertical plate | $N_{Sh,x} = \dfrac{k'x}{D} = 0.0299N_{Gr}^{2/5}N_{Sc}^{7/15}\times(1+0.494\,N_{Sc}^{2/3})^{-2/5}$<br>$N_{Sh,avg} = 0.0249N_{Gr}^{2/5}N_{Sc}^{7/15}\times(1+0.494\,N_{Sc}^{2/3})^{-2/5}$<br>$N_{Gr} = \dfrac{gx^3}{(\mu/\rho)^2}\left(\dfrac{\rho_\infty}{\rho_0}-1\right)$, $N_{Sh,avg} = \dfrac{k'_m L}{D}$ | [S] Low solute concentration and low transfer rates.<br>Use arithmetic concentration difference.<br>$N_{Gr} > 10^{10}$<br>Assumes laminar boundary layer is small fraction of total. | Skelland, p. 225 |
| H. Cross-corrugated plate (turbulence promoter for membrane systems) | $N_{Sh} = cN_{Re}^a N_{Sc}^{1/3}$ | [E] Entrance turbulent channel<br>For parallel flow and corrugations:<br>$N_{SC} = 1483$, $a = 0.56$, $c = 0.268$<br>$N_{SC} = 4997$, $a = 0.50$, $c = 0.395$<br>Corrugations perpendicular to flow:<br>$N_{SC} = 1483$, $a = 0.57$, $c = 0.368$<br>$N_{SC} = 4997$, $a = 0.52$, $c = 0.487$ | [98] |
| I. Turbulent, spinning disk | $N_{Sh} = \dfrac{k'd_{disk}}{D} = 5.6N_{Re}^{1.1}N_{Sc}^{1/3}$<br>$6\times10^5 < N_{Re} < 2\times10^6$, $120 < N_{Sc} < 1200$ | [E] Use arithmetic concentration difference.<br>$u = \omega d_{disk}/2$ where $\omega$ = rotational speed, radians/s.<br>$N_{Re} = \rho\omega d_{disk}^2/2\mu$ | [42]<br>Sherwood, Pigford, & Wilke, p. 241 |

Of limited utility. | Geankoplis p. 474<br>[57] p. 171<br>Skelland, p. 239<br>Taylor & Krishna, p. 250 |
| S. Tubes, turbulent, smooth tubes, Chilton-Colburn analogy | $j_D = j_H \le \dfrac{f}{2}$<br>If $\dfrac{f}{2} = 0.023 N_{Re}^{-0.2}$, $j_D = \dfrac{N_{Sh}}{N_{Re}N_{Sc}^{1/3}} = 0.023 N_{Re}^{-0.2}$<br>$N_{Sh} = \dfrac{k'd_t}{D}$, see Table 5-17G<br>$j_D = j_H = F(N_{Re}$, geometry and B.C.) | [E] Use log-mean concentration difference. Relating $j_D$ to $f/2$ approximate. $N_{Pr}$ and $N_{Sc}$ near 1.0. Low concentration. Results about 20% lower than experiment. $3 \times 10^4 \times N_{Re} \times 10^6$<br>[E] Good over wide ranges. | Bird, Stewart, & Lightfoot, pp. 400, 647<br>[38][40]<br>Skelland, p. 264<br>Taylor & Krishna, p. 251<br>Geankoplis, p. 475<br>Bird, Stewart, & Lightfoot, p. 647<br>[38] |
| T. Tubes, turbulent, smooth tubes, constant surface concentration, Prandtl analogy | $N_{Sh} = \dfrac{k'd_t}{D} = \dfrac{(f/2)N_{Re}N_{Sc}}{1 + 5\sqrt{f/2}(N_{Sc} - 1)}$<br>$\dfrac{f}{2} = 0.04 N_{Re}^{-0.25}$ | [T] Use arithmetic concentration difference. Improvement over Reynolds analogy. Best for $N_{Sc}$ near 1.0. | [57] p. 173<br>Skelland, p. 241 |
| U. Tubes, turbulent, smooth tubes, Constant surface concentration, Von Karman analogy | $N_{Sh} = \dfrac{(f/2)N_{Re}N_{Sc}}{1 + 5\sqrt{f/2}\left\{(N_{Sc} - 1) + \ln\left[1 + \dfrac{5}{6}(N_{Sc} - 1)\right]\right\}}$<br>$\dfrac{f}{2} = 0.04 N_{Re}^{-0.25}$ | [T] Use arithmetic concentration difference. $N_{Sh} = k'd_t/D$. Improvement over Prandtl, $N_{Sc} < 25$. | [57] p. 173<br>Skelland, p. 243<br>Taylor & Krishna, p. 250<br>[111] |
| V. Turbulent flow, tubes | $N_{St} = \dfrac{N_{Sh}}{N_{Pe}} = \dfrac{N_{Sh}}{N_{Re}N_{Sc}} = 0.0149\, N_{Re}^{-0.12} N_{Sc}^{-2/3}$ | [E] Smooth pipe data. Data fits within 4% except at $N_{Sc} > 20{,}000$, where experimental data is underpredicted. $N_{Sc} > 100$, $10^5 > N_{Re} > 2100$ | [80] |
| W. Turbulent flow, noncircular ducts | $d_{eq} = \dfrac{4 \text{ cross-sectional area}}{\text{wetted perimeter}}$ | Can be suspect for systems with sharp corners. Parallel plates: $d_{eq} = 4\dfrac{2hw}{2w + 2h}$ | Skelland, p. 289 |

*Author names refer to the General References list at the beginning of the Mass Transfer subsection (pp. 5-41, 5-42). Bracketed numbers refer to the table reference lists (p. 5-42).

**TABLE 5-20 Mass-Transfer Correlations for Flow Past Submerged Objects**

| Situation | Correlation | Comments E = Empirical, S = Semiempirical, T = Theoretical | References* |
|---|---|---|---|
| A. Single sphere | $N_{Sh} = \dfrac{k'_G p_{BLM} R T d_s}{PD} = \dfrac{2r}{r - r_s}$<br>$r/r_s$: 2 \| 5 \| 10 \| 50 \| ∞ (asymptotic limit)<br>$N_{Sh}$: 4.0 \| 2.5 \| 2.22 \| 2.04 \| 2.0 | [T] Use with log-mean concentration difference.<br>$r$ = distance from sphere, $r_s$, $d_s$ = radius and diameter of sphere.<br>No convection. | Skelland, p. 18 |
| B. Single sphere, creeping flow with forced convection | $N_{Sh} = \dfrac{k'd}{D} = [4.0 + 1.21(N_{Re} N_{Sc})^{2/3}]^{1/2}$<br>$N_{Sh} = \dfrac{k'd}{D} = a(N_{Re} N_{Sc})^{1/3}$<br>$a = 1.00 \pm 0.01$ | [T] Use with log-mean concentration difference.<br>Average over sphere. Numerical calculations.<br>$(N_{Re}N_{Sc}) < 10{,}000$ $N_{Re} < 1.0$. Constant sphere diameter.<br>Low mass-transfer rates.<br>[T] Fit to above ignoring molecular diffusion.<br>$1000 < (N_{Re}N_{Sc}) < 10{,}000$. | [33], Kirwan, p. 114<br>Sherwood, Pigford, & Wilke, p. 214 [76] p. 80<br>Sherwood, Pigford, & Wilke, p. 215 |
| C. Single spheres, molecular diffusion, and forced convection, low flow rates | $N_{Sh} = 2.0 + AN_{Re}^b N_{Sc}^c$, $b = 1/2$, $c = 1/3$<br>$A = 0.5$ to 0.62<br>$A = 0.60$.<br>$A = 0.95$.<br>$A = 0.95$.<br>$A = 0.544$.<br>$A = 0.575$, $b = 0.5$, $c = 0.35$<br>$A = 0.552$, $b = 0.53$, $c = 1/3$ | [E] Use with log-mean concentration difference.<br>Average over sphere.<br>Frössling Eq. **TABLE 5-21 Mass-Transfer Correlations for Drops, Bubbles, and Bubble Columns**

| Conditions | Correlations | Comments E = Empirical, S = Semiempirical, T = Theoretical | References* |
|---|---|---|---|
| A. Single liquid drop in immiscible liquid, drop formation, discontinuous (drop) phase coefficient | $\hat{k}_{d,f} = A\left(\frac{\rho_d}{M_d}\right)_{av}\left(\frac{D_d}{\pi t_f}\right)^{1/2}$<br>$A = 24/7$ (penetration theory), $A = 1.31$ (semiempirical value)<br>$A = \left[\frac{24}{7}(0.8624)\right]$ (extension by fresh surface elements) | [T,S] Use arithmetic mole fraction difference. Fits some, but not all, data. Low mass transfer rate. $M_d$ = mean molecular weight of dispersed phase; $t_f$ = formation time of drop<br>$k_{L,d}$ = mean dispersed liquid phase MT. coefficient k mole/[s · m² (mole fraction)]. | Skelland, p. 399 |
| B. Single liquid drop in immiscible liquid, drop formation, continuous phase coefficient | $k_{L,c} = 0.386 \times \left(\frac{\rho_c}{M_c}\right)_{av}\left(\frac{D_c}{t_f}\right)^{0.5}\left(\frac{\rho_c \sigma g_c}{\Delta\rho g t_f \mu_c}\right)^{0.407}\left(\frac{g t_f^2}{d_p}\right)^{0.148}$ | [E] Average absolute deviation 11% for 20 data points for 3 systems. | Skelland, p. 402<br>[105] p. 434 |
| C. Single liquid drop in immiscible liquid, free rise or fall, discontinuous phase coefficient, stagnant drops | $k_{L,d,m} = \frac{-d_p}{6t}\left(\frac{\rho_d}{M_d}\right)_{av}\ln\left\{\frac{6}{\pi^2}\sum_{j=1}^{\infty}\frac{1}{j^2}\exp\left[\left(\frac{-D_d j^2 \pi^2 t}{(d_p/2)^2}\right)\right]\right\}$ | [T] Use with log-mean mole fraction differences based on ends of column. $t$ = rise time. No continuous phase resistance. Stagnant drops are likely if drop is very viscous, quite small, or is coated with surface active agent. $k_{L,d,m}$ = mean dispersed liquid MT coefficient. | Skelland, p. 404<br>[105] p. 435 |
| D. Same as 5-21C | $\hat{k}_{L,d,m} = \frac{-d_p}{6t}\left(\frac{\rho_d}{M_d}\right)_{av}\ln\left[1 - \frac{\pi D_d^{1/2} t^{1/2}}{d_p/2}\right]$ | [S] See 5-21C. Approximation for fractional extractions less than 50%. | Skelland, p. 404<br>[105] p. 435 |
| E. Same as 5-21C, continuous phase coefficient, stagnant drops, spherical | $N_{Sh} = \frac{k_{L,c,m} d_c}{D_c} = 0.74\left(\frac{\rho_c}{M_c}\right)_{av} N_{Re}^{1/2}(N_{Sc})^{1/3}$ | [E] $N_{Re} = \upsilon_s d_p \rho_c / \mu_c$, $\upsilon_S$ = slip velocity between drop and continuous phase. | Skelland, p. 407<br>[104][105] p. 436 |
| F. Single bubble or drop with surfactant. Stokes flow. | $N_{Sh} = 2.0 + \alpha N_{Pe,}^{\beta} N_{Sh} = 2rk/D$<br>$\alpha = \frac{5.49}{A+6.10} + \frac{A}{A+28.64}$<br>$\beta = \frac{0.35A + 17.21}{A + 34.14}$<br>$2r = 2$ to 50 μm, $A = 2.8E4$ to $7.0E5$<br>$0.0026 < N_{Pe,s} < 340$, 2.1<br>$< N_{Ma} < 1.3E6$ $N_{Pe} = 1.0$ to $2.5 \times 10^4$,<br>$N_{Re} = 2.2 \times 10^{-6}$ to 0.034 | [T] $A$ = surface retardation parameter<br>$A = B\Gamma_o r/\mu D_s = N_{Ma} N_{Pe,s}$<br>$N_{Ma} = B\Gamma_o/\mu u$ = Marangoni no. $\Gamma$ = surfactant surface concentration, $B = -\partial\sigma/\partial\Gamma$ = constant<br>$N_{Pe,s}$ = surface Peclet number = $ur/D_s$<br>$D_s$ = surface diffusivity<br>$N_{Pe}$ = bulk Peclet number<br>For $A >> 1$ acts like rigid sphere:<br>$\beta \to 0.35$, $\alpha \to 1/2864 = 0.035$ | [89] |
| G. See oblate spheroid | $N_{Sh} = \frac{k_{L,c,m} d_3}{D_c} = 0.74\left(\frac{\rho_c}{M_c}\right)_{av}(N_{Re,3})^{1/2}(N_{Sc,c})^{1/3}$<br>$N_{Re,3} = \frac{\upsilon_s d_3 \rho_c}{\mu_c}$ | [E] Used with log-mean mole fraction. Differences based on ends of extraction column; 100 measured values ±2% deviation. Based on area oblate spheroid.<br>$\upsilon_s$ = slip velocity, $d_3 = \frac{\text{total drop surface area}}{\text{perimeter normal to flow}}$ | Skelland, pp. 285, 406, 407 |
| H. Single liquid drop in immiscible liquid, free rise or fall, discontinuous phase coefficient, circulating drops | $\hat{k}_{L,d,\text{circ}} = -\frac{d_p}{6\theta}\left(\frac{\rho_d}{M_d}\right)_{av}\ln\left[1 - \frac{R^{1/2}\pi D_d^{1/2}\theta^{1/2}}{d_p/2}\right]$ | [E] Used with mole fractions for extraction less than 50%, $R \approx 2.25$. | Skelland, p. 405 |
| I. Same as 5-21F | $N_{Sh} = \frac{\hat{k}_{L,d,\text{circ}} d_p}{D_d} = 31.4\left(\frac{\rho_d}{M_f}\right)_{av}\left(\frac{4D_d t}{d_p^2}\right)^{-0.34} N_{Sc,d}^{-0.125}\left(\frac{d_p \upsilon_s^2 \rho_c}{\sigma g_c}\right)^{-0.37}$ | [E] Used with log-mean mole fraction difference. $d_p$ = diameter of sphere with same volume as drop. $856 \le N_{Sc} \le 79{,}800$, $2.34 \le \sigma \le 4.8$ dynes/cm. | [105] p. 435<br>[106] |
| J. Liquid drop in immiscible liquid, free rise or fall, continuous phase coefficient, circulating single drops | $N_{Sh,c} = \frac{k'_{L,c} d_p}{D_d} = \left[2 + 0.463 N_{Re,drop}^{0.484} N_{Sc,c}^{0.339}\left(\frac{d_p g^{1/3}}{D_c^{2/3}}\right)\right.$<br>$F = 0.281 + 1.615K + 3.73K^2 - 1.874K^3$<br>$K = N_{Re,drop}^{1/8}\left(\frac{\mu_c}{\mu_d}\right)^{1/4}\left(\frac{\mu_c \upsilon_s}{\sigma g_c}\right)^{1/6}$ | [E] Used as an arithmetic concentration difference.<br>$N_{Re,drop} = \frac{d_p \upsilon_s \rho_c}{\mu_c}$<br>Solid sphere form with correction factor $F$. | [61] |
| K. Same as 5-20J, circulating, single drop | $N_{Sh} = \frac{k_{L,c} d_p}{D_c} = 0.6\left(\frac{\rho_c}{M_c}\right)_{av} N_{Re,drop}^{1/2} N_{Sc,c}^{1/2}$ | [E] Used as an arithmetic concentration difference. Low σ. | Skelland, p. 407 |
| L. Same as 5-20J, circulating swarm of drops | $k_{L,c} = 0.725\left(\frac{\rho_c}{M_c}\right)_{av} N_{Re,drop}^{-0.43} N_{Sc,c}^{-0.58} \upsilon_s (1 - \phi_d)$ | [E] Used as an arithmetic concentration difference. Low σ, disperse-phase holdup of drop swarm. $\phi_d$ = volume fraction dispersed phase. | Skelland, p. 407<br>[105] p. 436 |
| M. Liquid drops in immiscible liquid, free rise or fall, discontinuous phase coefficient, oscillating drops | $N_{Sh} = \frac{k_{L,d,\text{osc}} d_p}{D_d} = 0.32\left(\frac{\rho_d}{M_d}\right)_{av}\left(\frac{4D_d t}{d_p^2}\right)^{-0.14} N_{Re,drop}^{0.68}\left(\frac{\sigma^3 g_c^3 \rho_c^2}{g\mu_c^4 \Delta\rho}\right)^{0.10}$ | [E] Used with a log-mean mole fraction difference. Based on ends of extraction column.<br>$N_{Re,drop} = \frac{d_p \upsilon_s \rho_c}{\mu_c}$, $411 \le N_{Re} \le 3114$<br>$d_p$ = diameter of sphere with volume of drop. Average absolute deviation from data, 10.5%. Low interfacial tension (3.5–5.8 dyn), $\mu_c < 1.35$ centipoise. | Skelland, p. 406<br>[105] p. 435<br>[106] |

**TABLE 5-21 Mass-Transfer Correlations for Drops, Bubbles, and Bubble Columns** (*Continued*)

| Conditions | Correlations | Comments E = Empirical, S = Semiempirical, T = Theoretical | References* |
|---|---|---|---|
| N. Same as 5-21M | $k_{L,d,\mathrm{osc}} = \dfrac{0.00375 v_s}{1+\mu_d/\mu_c}$ | [T] Use with log-mean concentration difference. Based on end of extraction column. No continuous phase resistance. $k_{L,d,\mathrm{osc}}$ in cm/s, $v_s$ = drop velocity relative to continuous phase. | Sherwood, Pigford, & Wilke, p. 228<br>Skelland, p. 405 |
| O. Single liquid drops in gas, gas side coefficient | $\dfrac{\hat{k}_g M_g d_p P}{D_{\mathrm{gas}}\rho_g} = 2 + A N_{\mathrm{Re},g}^{1/2} N_{\mathrm{Sc},g}^{1/3}$<br>$A = 0.552$ or $0.60$<br>$N_{\mathrm{Re},g} = \dfrac{d_p \rho_g v_s}{\mu_g}$ | [E] Used for spray drying (arithmetic partial pressure difference).<br>$v_s$ = slip velocity between drop and gas stream. Sometimes written with $M_g P/r_g = RT$. | [68] p. 388<br>[90] |
| P. Single water drop in air, liquid side coefficient | $k_L = 2\left(\dfrac{D_L}{\pi t}\right)^{1/2}$, short contact times<br>$k_L = 10\dfrac{D_L}{d_p}$, long contact times | [T] Use arithmetic concentration difference. Penetration theory. $t$ = contact time of drop. Gives plot for $k_G a$ also. Air-water system. | [68] p. 389 |
| Q. Single bubbles of gas in liquid, continuous phase coefficient, very small bubbles | $N_{\mathrm{Sh}} = \dfrac{k_c' d_b}{D_c} = 1.0\,(N_{\mathrm{Re}} N_{\mathrm{Sc}})^{1/3}$ | [T] Solid-sphere Eq.<br>$d_b < 0.1$ cm, $k_c'$ is average over entire surface of bubble. | Sherwood, Pigford, & Wilke, p. 214 |
| R. Same as 5-21Q, medium to large bubbles | $N_{\mathrm{Sh}} = \dfrac{k_c' d_b}{D_c} = 1.13 (N_{\mathrm{Re}} N_{\mathrm{Sc}})^{1/2}$ | [T] Use arithmetic concentration difference. Droplet equation: $d_b > 0.5$ cm. | Sherwood, Pigford, & Wilke, p. 231 |
| S. Same as 5-21R | $N_{\mathrm{Sh}} = \dfrac{k_c' d_b}{D_c} = 1.13\,(N_{\mathrm{Re}} N_{\mathrm{Sc}})^{1/2}\left[\dfrac{d_b}{0.45+0.2 d_b}\right]$<br>$500 \le N_{\mathrm{Re}} \le 8000$ | [S] Use arithmetic concentration difference. Modification of above (5-21R), $d_b > 0.5$ cm. No effect SAA for $d_p > 0.6$ cm. | [62], Sherwood, Pigford, & Wilke, p. 231 |
| T. Taylor bubbles in single capillaries (square or circular) | $k_L a = 4.5\left(\dfrac{D u_G}{L_{\mathrm{uc}}}\right)^{1/2}\dfrac{1}{d_c}$<br>Applicable $\left(\dfrac{u_G+u_L}{L_{\mathrm{slug}}}\right)^{0.5} > 3 (s^{-0.5})$ | [E] Air-water<br>$L_{uc}$ = unit cell length, $L_{\mathrm{slug}}$ = slug length, $d_c$ = capillary i.d.<br>For most data $k_L a \pm 20\%$. | [110] |
| U. Gas-liquid mass transfer in monoliths | $k_L a \approx 0.1\left(\dfrac{P}{V}\right)^{1/4}$<br>$P/V$ = power/volume (kW/m$^3$), range = 100 to 10,000 | [E] Each channel in monolith is a capillary. Results are in expected order of magnitude for capillaries based on 5-21T.<br>$k_L$ is larger than in stirred tanks. | [70] |
| V. Rising small bubbles of gas in liquid, continuous phase. Calderbank and Moo-Young correlation | $N_{\mathrm{Sh}} = \dfrac{k_c' d_b}{D_c} = 2 + 0.31 (N_{\mathrm{Gr}})^{1/3} N_{\mathrm{Sc}}^{1/3}$, $d_b < 0.25$ cm<br>$N_{\mathrm{Ra}} = \dfrac{d_b^3 \lvert\rho_G - \rho_L\rvert g}{\mu_L D_L}$ = Raleigh number | [E] Use with arithmetic concentration difference. Valid for single bubbles or swarms. Independent of agitation as long as bubble size is constant. Recommended by [99]. Note that $N_{\mathrm{Ra}} = N_{\mathrm{Gr}} N_{\mathrm{Sc}}$. | [34] Geankoplis, p. 451<br>Kirwan, p. 119<br>Treybal, p. 156<br>[99] |
| W. Same as 5-21V, large bubbles | $N_{\mathrm{Sh}} = \dfrac{k_c' d_b}{D_c} = 0.42 (N_{\mathrm{Gr}})^{1/3} N_{\mathrm{Sc}}^{1/2}$, $d_b > 0.25$ cm<br>$\dfrac{\text{Interfacial area}}{\text{volume}} = a = \dfrac{6 H_g}{d_b}$ | [E] Use with arithmetic concentration difference. For large bubbles, $k_c'$ is independent of bubble size and independent of agitation or liquid velocity. Resistance is entirely in liquid phase for most gas-liquid mass transfer. $H_g$ = fractional gas holdup, volume gas/total volume. | [34] Geankoplis, p. 452<br>Kirwan, p. 119<br>[72] p. 249<br>[99] |
| X. Bubbles in bubble columns. Hughmark correlation | $N_{\mathrm{Sh}} = \dfrac{k_L d}{D} = 2 + b N_{\mathrm{Sc}}^{0.546} N_{\mathrm{Re}}^{0.779}\left(\dfrac{d g^{1/3}}{D^{2/3}}\right)^{0.116}$<br>$b = 0.061$ single gas bubbles<br>$b = 0.0187$ swarms of bubbles<br>$V_s = \dfrac{V_g}{\varphi_G} - \dfrac{V_L}{1-\varphi_G}$ | [E] $d$ = bubble diameter<br>Air–liquid. Recommended by [99] and Treybal. For swarms, calculate $N_{\mathrm{Re}}$ with slip velocity $V_s$.<br>$\varphi_G$ = gas holdup, $V_G$ = superficial gas velocity<br>Col. diameter = 0.025 to 1.1 m<br>$\rho_L'$ = 776 to 1696 kg/m$^3$, $\mu_L$ = 0.0009 to 0.152 Pa · s | [42]<br>[61]<br>Treybal, p. 144 |
| Y. Bubbles in bubble column | $k_L = \dfrac{0.15 D}{d_{Vs}}\left(\dfrac{\nu}{D}\right)^{1/2} N_{\mathrm{Re}}^{3/4}$ | [E] $d_{Vs}$ = Sauter mean bubble diameter, $N_{\mathrm{Re}} = d_{Vs} u_G \rho_L/\mu_L$. Recommended by [36] based on experiments in industrial system. | [36]<br>[97] |

See Table 5-22 for agitated systems.

**TABLE 5-22 Mass-Transfer Correlations for Particles, Drops, and Bubbles in Agitated Systems**

| Situation | Correlation | Comments E = Empirical, S = Semiempirical, T = Theoretical | References* |
|---|---|---|---|
| A. Solid particles suspended in agitated vessel containing vertical baffles, continuous phase coefficient | $\frac{k'_{LT}d_p}{D} = 2 + 0.6N_{Re,T}^{1/2}N_{Sc}^{1/3}$<br>Replace $v_{slip}$ with $v_T$ = terminal velocity. Calculate Stokes' law terminal velocity<br>$\upsilon_{Ts} = \frac{d_p^2\lvert\rho_p - \rho_c\rvert g}{18\mu_c}$<br>and correction factor:<br>$N_{Re,Ts}$: 1 \| 10 \| 100 \| 1000 \| 10,000 \| 100,000<br>$\upsilon_T/\upsilon_{Ts}$: 0.9 \| 0.65 \| 0.37 \| 0.17 \| 0.07 \| 0.023<br>Approximate: $k'_L = 2k'_{LT}$ | [S] Use log-mean concentration difference.<br>Modified Frossling equation:<br>$N_{Re,Ts} = \frac{\upsilon_{Ts}d_p\rho_c}{\mu_c}$<br>(Reynolds number based on Stokes' law.)<br>$N_{Re,T} = \frac{\upsilon_T d_p\rho_c}{\mu_c}$<br>(terminal velocity Reynolds number.)<br>$k'_L$ almost independent of $d_p$<br>Harriott [56] suggests different correction procedures. Range $k'_L/k'_{LT}$ is 1.5 to 8.0. | [56]<br>Sherwood, Pigford, & Wilke, pp. 220–222<br>[83]<br>[56] |
| B. Solid, neutrally buoyant particles, continuous phase coefficient | $N_{Sh} = \frac{k'_L d_p}{D} = 2 + 0.47N_{Re,p}^{0.62}N_{Sc}^{0.36}\left(\frac{d_{imp}}{d_{tank}}\right)^{0.17}$<br>Graphical comparisons are in Ref. 88, p. 116.<br>$N_{Sh} = 2 + 0.52N_{Re,p}^{0.52}N_{Sc}^{1/3}, N_{Re,p} < 1.0$ | [E] Use log-mean concentration difference.<br>Density unimportant if particles are close to neutrally buoyant. Also used for drops. Geometric effect ($d_{imp}/d_{tank}$) is usually unimportant.<br>Ref. [77] gives a variety of references on correlations.<br>[E] $E$ = energy dissipation rate per unit mass fluid<br>$= \frac{P_{g_c}}{V_{tank}\rho_c}$, $P$ = power, $N_{Re,p} = \frac{E^{1/3}d_p^{4/3}}{\nu}$<br>[E] Small particles | Kirwan, p. 115<br>[77] p. 132<br>Treybal, p. 523<br>Kirwan, p. 116 |
| C. Solid particles with significant density difference | $N_{Sh} = \frac{k'_L d_p}{D} = 2 + 0.44\left(\frac{d_p\upsilon_{slip}}{\nu}\right)^{1/2}N_{Sc}^{0.38}$ | [E] Use log-mean concentration difference.<br>$N_{Sh}$ standard deviation 11.1%. $v_{slip}$ calculated by methods given in reference. | [77]<br>[83] |
| D. Small solid particles, gas bubbles or liquid drops, $d_p < 2.5$ mm. Aerated mixing vessels | $N_{Sh} = \frac{k'_L d_p}{D} = 2 + 0.31\left(\frac{d_p^3\lvert\rho_p - \rho_c\rvert}{\mu_c D}\right)^{1/3}$ | [E] Use log-mean concentration difference<br>$g = 9.80665$ m/s$^2$. Second term RHS is free-fall or rise term. For large bubbles, see Table 5-21W. | [33] [50] p. 487<br>[72] p. 249 |
| E. Highly agitated systems; solid particles, drops, and bubbles; continuous phase coefficient | $k'_L N_{Sc}^{2/3} = 0.13\left[\frac{(P/V_{tank})\mu_c g_c}{\rho_c^2}\right]^{1/4}$ | [E] Use arithmetic concentration difference.<br>Use when gravitational forces overcome by agitation. Up to 60% deviation. Correlation prediction is low [77]. $(P/V_{tank})$ = power dissipated by agitator per unit volume liquid. | [34]<br>Geankoplis, p. 489<br>[83] |
| F. Gas bubble swarms in sparged tank reactors | $k'_L a = \left(\frac{\nu}{g^2}\right)^{1/3} = C\left[\frac{P/V_L}{\rho(\nu g^4)^{1/3}}\right]^a\left[\frac{qG}{V_L}\left(\frac{\nu}{g^2}\right)^{1/3}\right]^b$<br>Rushton turbines: $C = 7.94 \times 10^{-4}$, $a = 0.62$, $b = 0.23$.<br>Intermig® impellers: $C = 5.89 \times 10^{-4}$, $a = 0.62$, $b = 0.19$. | [E] Use arithmetic concentration difference.<br>Done for biological system, $O_2$ transfer.<br>$h_{tank}/D_{tank} = 2.1$; $P$ = power, kW. $V_L$ = liquid volume, m$^3$.<br>$q_G$ = gassing rate, m$^3$/s. $k'_L a = s^{-1}$.<br>Since $a$ = m$^2$/m$^3$, $\nu$ = kinematic viscosity, m$^2$/s. Low viscosity system. Better fit claimed with $q_G/V_L$ than with $u_G$ (see 5-22G and H). | [96] |
| G. Same as 5-22F, baffled tank with standard blade Rushton impeller | $k'_L a = 93.37\left(\frac{P}{V_L}\right)^{0.76}u_G^{0.45}$ | [E] Air-water. Same definitions as 5-22F.<br>$0.005 < u_G < 0.025$, $3.83 < N < 8.33$, $400 < P/V_L < 7000$<br>$h = D_{tank} = 0.305$ or 0.610 m. $V_G$ = gas volume, m$^3$, $N$ = stirrer speed, rpm. Method assumes perfect liquid mixing. | [50] [73] |
| H. Same as 5-22G, bubbles | $\frac{k'_L a d_{imp}^2}{D} = 0.060\left(\frac{d_{imp}^2 N\rho}{\mu_{eff}}\right)\left(\frac{d_{imp}^2 N^2}{g}\right)^{0.19}\left(\frac{\mu_{eff}u_G}{\sigma}\right)^{0.6}$ | [E] Use arithmetic concentration difference.<br>$O_2$ into aqueous glycerol solutions. $O_2$ into aqueous millet jelly solutions. Same definitions as 5-22G. | [73] [117] |
| I. Surface aerators for air-water contact | $\frac{k_L a}{N} = bN_p^{0.71}N_{Fr}^{0.48}N_{Re}^{0.82}\left(\frac{H}{d}\right)^{-0.54}\left(\frac{V}{d^3}\right)^{-1.08}$<br>$b = 7 \times 10^{-6}$, $N_p = P/(\rho N^3 d^5)$<br>$N_{Re} = Nd^2\rho_{liq}/\mu_{liq}$<br>$N_{Fr} = N^2 d/g$, $P/V = 90$ to 400 W/m$^3$ | [E] Three impellers: Pitched blade downflow turbine, pitched blade upflow turbine, standard disk turbine. Baffled cylindrical tanks 1.0- and 1.5-m id and 8.2 × 8.2-m square tank. Submergence optimized all cases. Good agreement with data.<br>$N$ = impeller speed, s$^{-1}$; $d$ = impeller diameter, m;<br>$H$ = liquid height, m; $V$ = liquid volume, m$^3$; $k_L a = s^{-1}$,<br>$g$ = acceleration gravity = 9.81 m/s$^2$ | [86] |
| J. Individual drops in LLE. Continuous phase coefficients | $Sh_{C,circ} \equiv (k_C\, d/D_{AC}) = (2/\pi^{0.5})\, Pe_C^{0.5}$<br>$Pe_C = (d\, u_t/D_{AC})$<br>$Sh_{C,rigid} = 2.43 + \{0.773\, Re_{drop}^{0.5} + 0.0103\, Re_{drop}\}Sc_C^{0.33}$<br>$(Sh_C - Sh_{C,rigid})/(Sh_{C,circ} - Sh_{C,rigid}) = 1 - \exp[-0.00418\, Pe_C^{0.42}]$ | [E] Clean circulating drops, Steiner's results for $10 < Re_{drop} < 1200$, $190 < Sc_C < 241000$, and $1000 < Pe_C < 10^6$,<br>[E] Rigid drops (common in dirty conditions), Steiner's results, $10^4 < Pe_C < 10^6$, Preferred for dirty conditions.<br>[E] Preferred for clean conditions between circulating & rigid. Steiner's results | [107]<br>[114] |
| K. Average drop size in LLE mixers | $\frac{d_p}{d_p^o} = 1 + 1.18\varphi_D\left(\frac{\sigma^2 g_c^2}{d_p^o\mu_C^2 g}\right)\left(\frac{\mu_C^4 g}{\Delta\rho\sigma^3 g_c^3}\right)^{0.62}\left(\frac{\Delta\rho}{\rho_C}\right)^{0.05}$ | [E] Baffled mixers. LLE data. $\Delta\rho = \lvert\rho_C - \rho_D\rvert \cdot d_p^o$ is from,<br>$\frac{d_p^{o^3}\rho_C^2 g}{\mu_C^2} = 29\left(\frac{V_{Liq\text{-}tank}^3\rho_C^2\mu_c g^4}{P^3 g_c^3}\right)^{0.32}\left(\frac{\sigma^3\rho_C g_c^3}{\mu_C^4 g}\right)^{0.14}$ | Treybal [114] |

See also Table 5-21.

**TABLE 5-23 Mass-Transfer Correlations for Fixed and Fluidized Beds**

Transfer is to or from particles

| Situation | Correlation | Comments E = Empirical, S = Semiempirical, T = Theoretical | References* |
|---|---|---|---|
| A. For gases, fixed and fluidized beds, Gupta and Thodos correlation | $j_H = j_D = \frac{2.06}{\varepsilon N_{Re}^{0.575}}, 90 \le N_{Re} \le A$<br>Equivalent:<br>$N_{Sh} = \frac{k' d_s}{D} = \frac{2.06}{\varepsilon} N_{Re}^{0.425} N_{Sc}^{1/3}$<br>For other shapes:<br>$\frac{\varepsilon j_D}{(\varepsilon j_D)_{sphere}} = 0.79$ (cylinder) or 0.71 (cube) | [E] For spheres. $N_{Re} = \frac{\upsilon_{super} d_p \rho}{\mu}$<br>$A = 2453$ (Skelland), $A = 4000$ [57].<br>For $N_{Re} > 1900$, $j_H = 1.05 j_D$. Heat transfer result is in absence of radiation.<br>Graphical results are available for $N_{Re}$ from 1900 to 10,300.<br>$a = \frac{\text{surface area}}{\text{volume}} = 6(1-\varepsilon)/d_p$<br>For spheres, $d_p$ = diameter.<br>For nonspherical: $d_p = 0.567 \sqrt{\text{Part. Surf. Area}}$ | [54] [55]<br>[57], p. 195<br>Skelland |
| B. For gases and liquids, fixed and fluidized beds | $j_D = \frac{0.4548}{\varepsilon N_{Re}^{0.4069}}, 10 \le N_{Re} \le 2000$<br>$j_D = \frac{N_{Sh}}{N_{Re} N_{Sc}^{1/3}}, N_{Sh} = \frac{k' d_s}{D}$ | [E] Packed spheres, deep bed. Average deviation ±20%, $N_{Re} = d_p v_{super} \rho / \mu$. Can use for fluidized beds.<br>$10 \le N_{Re} \le 4000$. | [46]<br>Geankoplis, p. 484 |
| C. For liquids, fixed bed, Wilson and Geankoplis correlation | $j_D = \frac{1.09}{\varepsilon N_{Re}^{2/3}}, 0.0016 < N_{Re} < 55$<br>$165 \le N_{Sc} \le 70{,}600, 0.35 < \varepsilon < 0.75$<br>Equivalent:<br>$N_{Sh} = \frac{1.09}{\varepsilon} N_{Re}^{1/3} N_{Sc}^{1/3}$<br>$j_D = \frac{0.25}{\varepsilon N_{Re}^{0.31}}, 55 < N_{Re} < 1500, 165 \le N_{Sc} \le 10{,}690$<br>Equivalent: $N_{Sh} = \frac{0.25}{\varepsilon} N_{Re}^{0.69} N_{Sc}^{1/3}$ | [E] Beds of spheres,<br>$N_{Re} = \frac{d_p V_{super} \rho}{\mu}$<br>Deep beds.<br>$N_{Sh} = \frac{k' d_s}{D}$ | Geankoplis, p. 484<br>[57], p. 195<br>Skelland, p. 287<br>[115] |
| D. For liquids, fixed beds, Ohashi et al. correlation | $N_{Sh} = \frac{k' d_s}{D} = 2 + 0.51 \left( \frac{E^{1/3} d_p^{4/3} \rho}{\mu} \right)^{0.60} N_{Sc}^{1/3}$<br>$E$ = Energy dissipation rate per unit mass of fluid<br>$= 50(1-\varepsilon)\varepsilon^2 C_{Do} \left( \frac{\upsilon_r^3}{d_p} \right)$, m²/s³<br>$= \left[ \frac{50(1-\varepsilon) C_D}{\varepsilon} \right] \left( \frac{\upsilon_{super}^3}{d_p} \right)$<br>General form:<br>$N_{Sh} = 2 + K \left( \frac{E^{1/3} d_p^{4/3} \rho}{\mu} \right)^{\alpha} N_{Sc}^{\beta}$ | [S] Applies to single particles, packed beds, two-phase tube flow, suspended bubble columns, and stirred tanks with different definitions of $E$. Correlates large amount of published data. Compares number of correlations, $v_r$ = relative velocity, m/s. In packed bed, $v_r = v_{super}/\varepsilon$.<br>$C_{Do}$ = single particle drag coefficient at $v_{super}$ calculated from $C_{Do} = A N_{Re_t}^{-m}$.<br>$N_{Re}$ — $A$ — $m$<br>0 to 5.8 — 24 — 1.0<br>5.8 to 500 — 10 — 0.5<br>>500 — 0.44 — 0<br>Ranges for packed bed:<br>$0.2 < \frac{E^{1/3} d_p^{4/3} \rho}{\mu} < 4600$<br>Compares different situations versus general correlation. | [81] |
| E. Electrolytic system. Pall rings. Transfer from fluid to rings. | Full liquid upflow, $N_{Re} d_e u / \nu = 80$ to 550:<br>$N_{Sh} = k_L d_e / D = 4.1 N_{Re}^{0.39} N_{Sc}^{1/3}$<br>Irrigated liquid downflow (no gas flow):<br>$N_{Sh} = 5.1 N_{Re}^{0.44} N_{Sc}^{1/3}$ | [E] $d_e$ = diameter of sphere with same surface area as Pall ring. Full liquid upflow agreed with literature values. Schmidt number dependence was assumed from literature values. In downflow, $N_{Re}$ used superficial fluid velocity. | [52] |
| F. For liquids, fixed and fluidized beds | $\varepsilon j_D = \frac{1.1068}{N_{Re}^{0.72}}, 1.0 < N_{Re} \le 10$<br>$\varepsilon j_D = \frac{N_{Sh}}{N_{Re} N_{Sc}^{1/3}}, N_{Sh} = \frac{k' d_s}{D}$ | [E] Spheres:<br>$N_{Re} = \frac{d_p \upsilon_{super} \rho}{\mu}$ | [45]<br>Geankoplis, p. 484 |
| G. For gases and liquids, fixed and fluidized beds, Dwivedi and Upadhyay correlation | $\varepsilon j_D = \frac{0.765}{N_{Re}^{0.82}} + \frac{0.365}{N_{Re}^{0.386}}$<br>Gases: $10 \le N_{Re} \le 15{,}000$.<br>Liquids: $0.01 \le N_{Re} \le 15{,}000$.<br>$N_{Re} = \frac{d_p \upsilon_{super} \rho}{\mu}, N_{Sh} = \frac{k' d_s}{D}$ | [E] Deep beds of spheres,<br>$j_D = \frac{N_{Sh}}{N_{Re} N_{Sc}^{1/3}}$<br>Best fit correlation at low conc. [39]<br>Based on 20 gas studies and 17 liquid studies. | [45] [57] p. 196<br>[39] |
| H. For gases and liquids, fixed bed | $j_D = 1.17 N_{Re}^{-0.415}, 10 \le N_{Re} \le 2500$<br>$j_D = \frac{k'}{\upsilon_{av}} \frac{p_{BM}}{P} N_{Sc}^{2/3}$ | [E] Spheres: Variation in packing that changes $\varepsilon$ not allowed for. Extensive data referenced. $0.5 < N_{Sc} < 15{,}000$. Show comparisons with other results.<br>$N_{Re} = \frac{d_p \upsilon_{super} \rho}{\mu}$ | Sherwood, Pigford, & Wilke, p. 241 |

**TABLE 5-23 Mass-Transfer Correlations for Fixed and Fluidized Beds** (*Continued*)

| Situation | Correlation | Comments E = Empirical, S = Semiempirical, T = Theoretical | References* |
|---|---|---|---|
| I. For liquids, fixed and fluidized beds, Rahman and Streat correlation | $N_{Sh} = \frac{0.86}{\varepsilon} N_{Re} N_{Sc}^{1/3}, 2 \le N_{Re} \le 25$ | [E] Can be extrapolated to $N_{Re} = 2000$. $N_{Re} = d_p v_{super} \rho/\mu$. Done for neutralization of ion exchange resin. | [88] |
| J. Size exclusion chromatography of proteins | $N_{Sh} = \frac{k_L d}{D} = \frac{1.903}{\varepsilon} N_{Re}^{1/3} N_{Sc}^{1/3}$ | [E] Slow mass transfer with large molecules. Aqueous solutions. Modest increase in $N_{Sh}$ with increasing velocity. | [58] |
| K. For liquids and gases, Ranz and Marshall correlation | $N_{Sh} = \frac{k'd}{D} = 2.0 + 0.6 N_{Sc}^{1/3} N_{Re}^{1/2}$<br>$N_{Re} = \frac{d_p \upsilon_{super} \rho}{\mu}$ | [E] Based on freely falling, evaporating spheres (see 5-20C). Has been applied to packed beds, prediction is low compared to experimental data. Limit of 2.0 at low $N_{Re}$ is too high. Not corrected for axial dispersion. | [23] p. 214, [90]<br>[112]<br>[83] |
| L. For liquids and gases, Wakao and Funazkri correlation | $N_{Sh} = 2.0 + 1 N_{Sc}^{1.1/3} N_{Re}^{0.6}, 3 < N_{Re} < 10{,}000$<br>$N_{Sh} = \frac{k'_{film} d_p}{D}, N_{Re} = \frac{\rho_f \upsilon_{super} d_p}{\mu}$<br>$\frac{\varepsilon D_{axial}}{D} = 10 + 0.5 N_{Sc} N_{Re}$ | [E] Correlate 20 gas studies and 16 liquid studies. Corrected for axial dispersion. Graphical comparison with data shown [23, p. 215], and [112].<br>$D_{axial}$ is axial dispersion coefficient. | [23] p. 214<br>[112] |
| M. Semifluidized or expanded bed. Liquid-solid transfer. | $N_{Sh} = \frac{k_{film} d_p}{D} = 2 + 1.5 (1 - \varepsilon_L) N_{Re}^{1/3} N_{Sc}^{1/3}$<br>$N_{Re} = \rho_p d_p u/\mu\varepsilon_L; N_{Sc} = \mu/\rho D$ | [E] $\varepsilon_L$ = liquid-phase void fraction, $\rho_p$ = particle density, $\rho$ = fluid density, $d_p$ = particle diameter. Fits expanded bed chromatography in viscous liquids. | [48]<br>[116] |
| N. Mass-transfer structured packing and static mixers. Liquid with or without fluidized particles. Electrochemical | Fixed bed:<br>$j' = 0.927 N_{Re'}^{0.572}, N'_{Re} < 219$<br>$j' = 0.443 N_{Re'}^{-0.435}, 219 < N'_{Re} < 1360$<br>Fluidized bed with particles:<br>$j' = 6.02 N_{Re}^{-0.885}$, or $j' = 16.40 N_{Re'}^{-0.950}$<br>Natural convection:<br>$N_{Sh} = 0.252 (N_{Sc} N_{Gr})^{0.299}$<br>Bubble columns:<br>Structured packing:<br>$N_{St} = 0.105 (N_{Re} N_{Fr} N_{Sc}^2)^{-0.268}$<br>Static mixer: $N_{St} = 0.157 (N_{Re} N_{Fr} N_{Sc}^2)^{-0.298}$ | [E] = Sulzer packings, $j' = \frac{k \cos\beta}{\upsilon} N_{Sc}^{2/3}$,<br>$\beta$ = corrugation incline angle.<br>$N_{Re'} = v' d'_h \rho/\mu$, $v' = v_{super}/(\varepsilon \cos\beta)$,<br>$d'_h$ = channel side width.<br>Particles enhance mass transfer in laminar flow for natural convection. Good fit with correlation of Ray et al., *Intl. J. Heat Mass Transfer* **41:** 1693 (1998). $N_{Gr} = g \Delta \rho Z^3 \rho/\mu^2$,<br>$Z$ = corrugated plate length. Bubble column results fit correlation of Neme et al., *Chem. Eng. Technol.* **20:** 297 (1997) for structured packing.<br>$N_{St}$ = Stanton number = $kZ/D$<br>$N_{Fr}$ = Froude number = $v^2_{super}/gz$ | [35] |
| O. Liquid fluidized beds | $N_{Sh} = 0.250 N_{Re}^{0.023} N_{Ga}^{0.306} \left(\frac{\rho_s - \rho}{\rho}\right)^{0.282} N_{Sc}^{0.410}$ $(\varepsilon < 0.85)$<br>$N_{Sh} = 0.304 N_{Re}^{-0.057} N_{Ga}^{0.332} \left(\frac{\rho_s - \rho}{\rho}\right)^{0.297} N_{Sc}^{0.404}$ $(\varepsilon > 0.85)$<br>This can be simplified (with slight loss in accuracy at high $\varepsilon$) to<br>$N_{Sh} = 0.245 N_{Ga}^{0.323} \left(\frac{\rho_s - \rho}{\rho}\right)^{0.300} N_{Sc}^{0.400}$ | [E] Correlate amount of data from literature. Predicts very little dependence of $N_{Sh}$ on velocity. Compare large number of published correlations.<br>$N_{Sh} = \frac{k'_L d_p}{D}, N_{Re} = \frac{d_p \rho \upsilon_{super}}{\mu}, N_{Ga} = \frac{d_p^3 \rho^2 g}{\mu^2}$,<br>$N_{Sc} = \frac{\mu}{\rho D}$<br>$1.6 < N_{Re} < 1320, 2470 < N_{Ga} < 4.42 \times 106$<br>$0.27 < \frac{\rho_s - \rho}{\rho} < 1.114, 305 < N_{Sc} < 1595$ | [109] |
| P. Liquid film flowing over solid particles with air present, trickle bed reactors, fixed bed | $N_{Sh} = \frac{k_L}{aD} = 1.8 N_{Re}^{1/2} N_{Sc}^{1/3}, 0.013 < N_{Re} < 12.6$<br>two-phases, liquid trickle, no forced flow of gas.<br>$N_{Sh} = 0.8 N_{Re}^{1/2} N_{Sc}^{1/3}$, one-phase, liquid only. | [E] $N_{Re} = \frac{L}{a\mu}$, irregular granules of benzoic acid,<br>$0.29 \le d_p \le 1.45$ cm.<br>$L$ = superficial liquid flow rate, kg/m$^2$s.<br>$a$ = surface area/col. volume, m$^2$/m$^3$. | [95] |
| Q. Supercritical fluids in packed bed | $\frac{N_{Sh}}{(N_{Sc} N_{Gr})^{1/4}} = 0.5265 \left(\frac{N_{Re}^{1/2} N_{Sc}^{1/3}}{(N_{Sc} N_{Gr})^{1/4}}\right)^{1.6808} + 2.48 \left\lvert \left(\frac{N_{Re}^2 N_{Sc}^{1/3}}{N_{Gr}}\right)^{0.6439} - 0.8767 \right\rvert^{1.553}$ | [E] Natural and forced convection. $0.3 < N_{Re} < 135$. | [74] |
| R. Co current gas-liquid flow in fixed beds | Downflow in trickle bed and up flow in bubble columns. | Literature review and meta-analysis. Analyzed both downflow and upflow. Recommendations for best mass and heat-transfer correlations (see reference). | [71] |

NOTE: For $N_{Re} < 3$ convective contributions which are not included may become important. Use with logarithmic concentration difference (integrated form) or with arithmetic concentration difference (differential form).

*Author names refer to the General References list at the beginning of the Mass Transfer subsection (pp. 5-41, 5-42). Bracketed numbers refer to the table reference lists (p. 5-42).

correlations include transfer to or from one fluid to either a second fluid or a solid. Many of the correlations are for $k_L$ and $k_G$ values obtained from dilute systems where $x_{BM}\approx 1.0$ and $y_{BM}\approx 1.0$. Each table is for a specific geometry or type of contactor, starting with flat plates (Table 5-17); then wetted wall columns (Table 5-18); flow in pipes and ducts (Table 5-19); submerged objects (Table 5-20); drops and bubbles (Table 5-21); agitated systems (Table 5-22); packed beds of particles for adsorption, ion exchange, and chemical reaction (Table 5-23); and finishing with packed bed two-phase contactors for distillation, absorption, and other unit operations (Table 5-24). For simple geometries, one may be able to determine a theoretical (T) form of the mass-transfer correlation. For very complex geometries, only an empirical (E) form can be found. In systems of intermediate complexity, semiempirical (S) correlations in which the form is determined from theory and the coefficients from experiment are often useful. Although the major limitations and constraints in use are usually included in the tables, obviously many details cannot be included in this summary form. Readers are strongly encouraged to check the references including the original paper before using the correlations in important situations. Note that even authoritative sources occasionally have typographical errors in the fairly complex correlation equations. The original papers will often include figures comparing the correlations with data.

Although extensive, these tables are not meant to be encyclopedic, and other sources such as Skelland, who extensively surveys older mass-transfer correlations, and Benitez, who surveys more recent correlations, should also be consulted. The extensive review of bubble column systems (see Table 5-21) by Shah et al. [*AIChE J.* **28:** 353 (1982)] includes estimation of bubble size, gas holdup, interfacial area $k_L a$, and the liquid dispersion coefficient. For correlations for particle-liquid mass transfer in stirred tanks (part of Table 5-22) see the review by Pangarkar et al. [*Ind. Eng. Chem. Res.* **41:** 4141 (2002)]. Mass-transfer correlations for membrane separators are reviewed by Sirkar [103]. For mass transfer in distillation, absorption, and extraction in packed beds (Table 5-24), see also the appropriate sections in this handbook and the review by Wang, Yuan, and Yu [*Ind. Eng. Chem. Res.* **44:** 8715 (2005)]. Mass transfer and interfacial area for absorption in packed beds for the specific problem of postcombustion carbon dioxide capture are reviewed by Mirzaei, Shamiri, and Aroua [*Rev. Chem. Engr.* **31:** 521 (2015)].

Since often several correlations are applicable, how does one choose the correlation to use? First, the engineer must determine which correlations are closest to the current situation. This involves recognizing the similarity of geometries, which is often challenging, and checking that the range of parameters in the correlation is appropriate. For example, the Bravo, Rocha, and Fair correlation for distillation with structured packings with triangular cross-sectional channels (Table 5-24H) uses the Johnstone and Pigford correlation for rectification in vertical wetted wall columns (Table 5-18E). Recognizing that this latter correlation pertains to a rather different application and geometry was a nontrivial step in the process of developing a correlation. If several correlations appear to be applicable, check to see if the correlations have been compared to one another and to the data. When a detailed comparison of correlations is not available, the following heuristics may be useful:

1. Mass-transfer coefficients are derived from models. They must be employed in a similar model. For example, if an arithmetic concentration difference was used to determine $k$, that $k$ should only be used in a mass-transfer expression with an arithmetic concentration difference.
2. Semiempirical correlations are often preferred to purely empirical or purely theoretical correlations. Purely empirical correlations are dangerous to use for extrapolation. Purely theoretical correlations may predict trends accurately, but they can be several orders of magnitude off in the value of $k$.
3. Correlations with broader databases are often preferred.
4. The analogy between heat and mass transfer holds over wider ranges than the analogy between mass and momentum transfer. Good heat-transfer data (without radiation) can often be used to predict mass-transfer coefficients.
5. More recent data are often preferred to older data, since end effects are better understood, the new correlation often builds on earlier data and analysis, and better measurement techniques are often available.
6. With complicated geometries, the product of the interfacial area per volume and the mass-transfer coefficient is required. Correlations of $ka_p$ or of HTU are more accurate than individual correlations of $k$ and $a_p$ since the measurements are simpler to determine the product $ka_p$ or HTU.
7. Finally, if a mass-transfer coefficient looks too good to be true, it probably is incorrect.

**Volumetric Mass-Transfer Coefficients $\hat{K}_G a$ and $\hat{K}_L a$** Experimental determinations of the individual mass-transfer coefficients $\hat{k}_G$ and $\hat{k}_L$ and of the effective interfacial area $a$ involve the use of extremely difficult techniques, and therefore such data are not plentiful. More often, column experimental data are reported in terms of overall volumetric coefficients, which normally are defined as follows:

$$K'_G a = n_A/(h_T S_{pT}\Delta y^{\circ}_{1m}) \tag{5-308}$$

and

$$K'_L a = n_A/(h_T S\,\Delta x^{\circ}_{1m}) \tag{5-309}$$

where $K'_G a$ = overall volumetric gas-phase mass-transfer coefficient, $K'_L a$ = overall volumetric liquid-phase mass-transfer coefficient, $n_A$ = overall rate of transfer of solute $A$, $h_T$ = total packed depth in tower, $S$ = tower cross-sectional area, $p_T$ = total system pressure employed during the experiment, and $\Delta x^{\circ}_{1m}$ and $\Delta y^{\circ}_{1m}$ are defined as

$$\Delta y^{*}_{1m}=\frac{(y-y^*)_1-(y-y^*)_2}{\ln[(y-y^*)_1/(y-y^*)_2]} \tag{5-310}$$

and

$$\Delta x^{*}_{1m}=\frac{(x^*-x)_2-(x^*-x)_2}{\ln[(x^*-x)_2/(x^*-x)_1]} \tag{5-311}$$

where subscripts 1 and 2 refer to the bottom and top of the tower, respectively.

Experimental $K'_G a$ and $K'_L a$ data are available for most absorption and stripping operations of commercial interest (see Table 5-24 and Sec. 14). The solute concentrations employed in these experiments normally are very low, so that $K'_L a \doteq \hat{K}_L a$ and $K'_G a p_T \doteq \hat{K}_G a$, where $p_T$ is the total pressure employed in the actual experimental-test system. Unlike the individual gas-film coefficient $\hat{k}_G a$, the overall coefficient $\hat{K}_G a$ will vary with the total system pressure except when the liquid-phase resistance is negligible (i.e., when either $m = 0$ or $\hat{K}_L a$ is very large, or both).

Extrapolation of $K'_G a$ data for absorption and stripping to conditions other than those for which the original measurements were made can be extremely risky, especially in systems involving chemical reactions in the liquid phase. One therefore would be wise to restrict the use of overall volumetric mass-transfer coefficient data to conditions not too far removed from those employed in the actual tests. The most reliable data for this purpose would be those obtained from an operating commercial unit of similar design.

Experimental values of $H_{OG}$ and $H_{OL}$ for a number of distillation systems of commercial interest are also readily available (e.g., see Table 5-24). Extrapolation of the data or the correlations to conditions that differ significantly from those used for the original experiments is risky. For example, pressure has a major effect on vapor density and thus can affect the hydrodynamics significantly. Changes in flow patterns affect both mass-transfer coefficients and interfacial area.

**Analogies** Analogies have been important in the study of mass transfer since Fick modeled his analysis of mass transfer on Fourier's analysis of heat transfer. If the underlying mechanisms for heat, mass, and momentum transfer are identical (e.g., transfer by eddies in turbulent flow), analogies are useful. If the underlying mechanisms are different (e.g., radiation in heat transfer), analogies do not apply. Reynolds developed an analogy (see Cussler for details) that is most commonly applied to turbulent flow in tubes (Table 5-19R)

$$\frac{k'}{\nu} = \frac{h}{\rho c_p \nu} = \frac{f}{2} \tag{5-312}$$

where $h$ is the heat-transfer coefficient, $c_p$ is the heat capacity, $f$ is the Fanning friction factor, and $\nu$ is a characteristic velocity. Since the Reynolds analogy is of limited utility, improved analogies for flow in tubes were developed by Prandtl (Table 5-19T) and Von Karman (Table 5-19U).

Chilton and Colburn [38] developed an empirical analogy that provided a better fit of experimental data. The general form of their analogy is

$$\frac{k'}{\nu}(N_{Sc})^{2/3} = \frac{h}{\rho c_p \nu}(N_{Pr})^{2/3} = \frac{f}{2} \quad \text{or} \quad j_D = j_H = f/2 \tag{5-313}$$

Specific applications are included in Tables 5-17A, 5-17E, and 5-19S.

The Chilton-Colburn analogy [38, 40, 68] is frequently used to develop estimates of the mass-transfer rates based on heat-transfer data. Extrapolation of experimental $j_M$ or $j_H$ data obtained with gases to predict liquid systems (and vice versa) should be approached with caution, however. When pressure-drop or friction-factor data are available, one may be able to place an upper bound on the rates of heat and mass transfer of $f/2$. In distillation columns there are more mass-transfer data than heat-transfer data, and the Chilton-Colburn analogy is used to estimate heat-transfer rates. The Chilton-Colburn analogy can be used for simultaneous heat and mass transfer as long as the concentration and temperature fields are independent [Venkatesan and Fogler, *AIChE J.* **50:** 1623 (2004)].

**Effects of System Physical Properties on $\hat{k}_G$ and $\hat{k}_L$** When one is designing packed towers for nonreacting gas-absorption systems for which no experimental data are available, it is necessary to make corrections for differences in composition between the existing test data and the system in question. For example, ammonia-water test data (see Table 5-24B) can be used to estimate $H_G$, and the oxygen desorption data (see Table 5-24A) can be used to estimate $H_L$. The method for doing this is illustrated in Table 5-24E. There is some conflict on whether the value of the exponent for the Schmidt number is 0.5 or 2/3 [Yadav and Sharma, *Chem. Eng. Sci.* **34:** 1423 (1979)]. Despite this disagreement, this method is extremely useful, especially for absorption and stripping systems. If one is in doubt about the exponent, we recommend using 2/3, the value used in the Chilton-Colburn analogy.

Note that the influence of substituting solvents of widely differing viscosities upon the interfacial area $a$ can be very large. One therefore should be cautious about extrapolating $\hat{k}_L a$ data to account for viscosity effects between different solvent systems.

**Influence of Chemical Reactions on $\hat{k}_G$ and $\hat{k}_L$** When a chemical reaction occurs, the transfer rate may be influenced by the chemical reaction as well as by the purely physical processes of diffusion and convection within the two phases. Since this situation is common in gas absorption, gas absorption will be the focus of this discussion. One must consider the impacts of chemical equilibrium and reaction kinetics on the absorption rate in addition to accounting for the effects of gas solubility, diffusivity, and system hydrodynamics.

There is no sharp dividing line between pure physical absorption and absorption controlled by the rate of a chemical reaction. Most cases fall in an intermediate range in which the rate of absorption is limited both by the resistance to diffusion and by the finite velocity of the reaction. Even in these intermediate cases the equilibria between the various diffusing species involved in the reaction may affect the rate of absorption.

The gas-phase rate coefficient $\hat{k}_G$ is not affected by chemical reactions taking place in the liquid phase. If the liquid-phase chemical reaction is extremely fast and irreversible, the rate of absorption may be governed completely by the resistance to diffusion in the gas phase. In this case the absorption rate may be estimated by knowing only the gas-phase rate coefficient $\hat{k}_G$ or else the height of 1 gas-phase transfer unit $H_G = G_M/(\hat{k}_G a)$.

Note that the highest possible absorption rates will occur under conditions in which the liquid-phase resistance is negligible and the equilibrium back pressure of the gas over the solvent is zero. Such situations would exist, for instance, for $NH_3$ absorption into an acid solution, for $SO_2$ absorption into an alkali solution, for vaporization of water into air, and for $H_2S$ absorption from a dilute-gas stream into a strong alkali solution, provided there is a large excess of reagent in solution to consume all the dissolved gas. This is known as the *gas-phase mass-transfer limited condition*, when both the liquid-phase resistance and the back pressure of the gas equal zero. Even when the reaction is sufficiently reversible to allow a small back pressure, the absorption may be gas-phase-controlled, and the values of $\hat{k}_G$ and $H_G$ that would apply to a physical absorption process will govern the rate.

The liquid-phase rate coefficient $\hat{k}_L$ is strongly affected by fast chemical reactions and generally increases with increasing reaction rate. Indeed, the condition for zero liquid-phase resistance $(m/\hat{k}_L)$ implies that either the equilibrium back pressure is negligible or $\hat{k}_L$ is very large, or both. Frequently, even though reaction consumes the solute as it is dissolving, thereby enhancing both the mass-transfer coefficient and the driving force for absorption, the reaction rate is slow enough that the liquid-phase resistance must be taken into account. This may be due either to an insufficient supply of a second reagent or to an inherently slow chemical reaction.

In any event the value of $\hat{k}_L$ in the presence of a chemical reaction normally is larger than the value found when only physical absorption occurs, $\hat{k}_L^0$. This has led to the presentation of data on the effects of chemical reaction in terms of the *reaction factor* or *enhancement factor,* defined as

$$\phi = \hat{k}_L / \hat{k}_L^0 \geq 1 \tag{5-314}$$

where $\hat{k}_L$ = mass-transfer coefficient with reaction and $\hat{k}_L^0$ = mass-transfer coefficient for pure physical absorption. It is important to understand that when chemical reactions are involved, this definition of $\hat{k}_L$ is based on the driving force, defined as the difference between the concentration of *unreacted* solute gas at the interface and in the bulk of the liquid. A coefficient based on the total of both unreacted and reacted gas could have values *smaller* than the physical absorption mass-transfer coefficient $\hat{k}_L^0$.

When liquid-phase resistance is important, particular care should be taken in employing any given set of experimental data to ensure that the equilibrium data used conform with those employed by the original author in calculating values of $\hat{k}_L$ or $H_L$. Extrapolation to widely different concentration ranges or operating conditions should be made with caution, since the mass-transfer coefficient $\hat{k}_L$ may vary in an unexpected fashion, owing to changes in the apparent chemical reaction mechanism.

Generalized prediction methods for $\hat{k}_L$ and $H_L$ do not apply when chemical reaction occurs in the liquid phase, and therefore one must use actual operating data for the particular system in question. A discussion of the various factors to consider in designing gas absorbers and strippers when chemical reactions are involved is presented by Astarita, Savage, and Bisio, *Gas Treating with Chemical Solvents*, Wiley, New York, 1983 and by Kohl and Nielsen, *Gas Purification,* 5th ed., Gulf Publishing, Houston, Tex., 1997.

**Effective Interfacial Mass-Transfer Area $a$** To determine the mass-transfer rate, one needs the interfacial area in addition to the mass-transfer coefficient. In a packed tower of constant cross-sectional area $S$ the differential change in solute flow per unit time is given by

$$-d(G_M S y) = N_A a \, dV = N_A a S \, dh \tag{5-315}$$

where $a$ = interfacial area effective for mass transfer per unit of packed volume and $V$ = packed volume. Owing to incomplete wetting of the packing surfaces and to the formation of areas of stagnation in the liquid film,

the effective area normally is significantly less than the total external area of the packing pieces.

For packed beds of particles, $a$ can be estimated as shown in Table 5-23A. For packed beds in distillation, absorption, and so on in Table 5-24, the interfacial area per volume is usually included with the mass-transfer coefficient in the correlations for HTU. For agitated liquid-liquid systems, the interfacial area can be estimated from the dispersed phase holdup and mean drop size correlations. Godfrey, Obi, and Reeve [*Chem. Engr. Prog.* **85:** 61 (Dec. 1989)] summarize these correlations. For many systems,

$$\bar{d}_{\text{drop}}/d_{\text{imp}} = (\text{const})N_{\text{We}}^{-0.6} \quad \text{where} \quad N_{\text{We}} = \rho_c N^2 d_{\text{imp}}^3/\sigma \tag{5-316}$$

Piché, Grandjean, and Larachi [*Ind. Eng. Chem. Res.* **41:** 4911 (2002)] developed two correlations for reconciling the gas-liquid mass-transfer coefficient and interfacial area in randomly packed towers. The correlation for the interfacial area was a function of five dimensionless groups, and it yielded a relative error of 22.5 percent for 325 data points. That equation, when combined with a correlation for $N_{\text{Sh}}$ as a function of four dimensionless groups, achieved a relative error of 24.4 percent, for 3455 data points for the product $k_G'a$.

The effective interfacial area depends on a number of factors, as discussed in a review by Charpentier [*Chem. Eng. J.* **11:** 161 (1976)]. Among these factors are (1) the shape and size of packing, (2) the packing material ( for example, plastic generally gives smaller interfacial areas than either metal or ceramic), (3) the liquid mass velocity, and (4) for small-diameter towers, the column diameter.

Whereas the interfacial area generally increases with increasing liquid rate, it apparently is relatively independent of the superficial gas mass velocity below the flooding point. According to Charpentier's review, it appears valid to assume that the interfacial area is independent of the column height when specified in terms of unit packed volume (i.e., as $a$). Also, the existing data for chemically reacting gas-liquid systems (mostly aqueous electrolyte solutions) indicate that the interfacial area is independent of the chemical system. However, this situation may not hold true for systems involving large heats of reaction.

Rizzuti et al. [*Chem. Eng. Sci.* **36:** 973 (1981)] examined the influence of solvent viscosity upon the effective interfacial area in packed columns and concluded that for the systems studied the effective interfacial area $a$ was proportional to the kinematic viscosity raised to the 0.7 power. Thus, the hydrodynamic behavior of a packed absorber is strongly affected by viscosity effects. Surface-tension effects also are important, as expressed in the work of Onda et al. [82] (see Table 5-24C).

**Concluding Comment** In developing correlations for the mass-transfer coefficients $k_G$ and $k_L$, various authors have assumed different but internally compatible correlations for the effective interfacial area $a$. It therefore would be inappropriate to mix the correlations of different authors unless it has been demonstrated that there is a valid area of overlap.

### Nomenclature and Units*

In this listing, symbols used in this section are defined in a general way and appropriate SI units are given. Specific definitions, as denoted by subscripts, are stated at the place of application in the section. Some specialized symbols used in the section are defined only at the place of application. Some symbols have more than one definition; the appropriate one is identified at the place of application.

| Symbol | Definition | SI units | U.S. Customary System units |
|---|---|---|---|
| $a$ | Pressure wave velocity | m/s | ft/s |
| $A$ | Area | $m^2$ | $ft^2$ |
| $b$ | Wall thickness | m | in |
| $b$ | Channel width | m | ft |
| $c$ | Acoustic velocity | m/s | ft/s |
| $c_f$ | Friction coefficient | Dimensionless | Dimensionless |
| $C$ | Conductance | $m^3/s$ | $ft^3/s$ |
| Ca | Capillary number | Dimensionless | Dimensionless |
| $C_0$ | Discharge coefficient | Dimensionless | Dimensionless |
| $C_D$ | Drag coefficient | Dimensionless | Dimensionless |
| $d$ | Diameter | m | ft |
| $D$ | Diameter | m | ft |
| De | Dean number | Dimensionless | Dimensionless |
| $E$ | Elastic modulus | Pa | $lbf/in^2$ |
| Eo | Eotvos number | Dimensionless | Dimensionless |
| $f$ | Fanning friction factor | Dimensionless | Dimensionless |
| $f$ | Vortex shedding frequency | 1/s | 1/s |
| $F$ | Force | N | lbf |
| $F$ | Cumulative residence time distribution | Dimensionless | Dimensionless |
| Fr | Froude number | Dimensionless | Dimensionless |
| $g$ | Acceleration of gravity | $m/s^2$ | $ft/s^2$ |
| $G$ | Mass flux | $kg/(m^2 \cdot s)$ | $lbm/(ft^2 \cdot s)$ |
| $h$ | Enthalpy per unit mass | J/kg | Btu/lbm |
| $h$ | Liquid depth | m | ft |
| $k$ | Ratio of specific heats | Dimensionless | Dimensionless |
| $k$ | Kinetic energy of turbulence | J/kg | $ft \cdot lbf/lbm$ |
| $K$ | Power law coefficient | $kg/(m \cdot s^{2-n})$ | $lbm/(ft \cdot s^{2-n})$ |
| $l_v$ | Viscous losses per unit mass | J/kg | $ft \cdot lbf/lbm$ |
| $L$ | Length | m | ft |
| $\dot{m}$ | Mass flow rate | kg/s | lbm/s |
| $M$ | Mass | kg | lbm |
| $M$ | Mach number | Dimensionless | Dimensionless |
| $M$ | Morton number | Dimensionless | Dimensionless |
| $M_w$ | Molecular weight | kg/kgmol | lbm/lbmol |
| $n$ | Power law exponent | Dimensionless | Dimensionless |
| $N_b$ | Blend time number | Dimensionless | Dimensionless |
| $N_P$ | Power number | Dimensionless | Dimensionless |
| $N_Q$ | Pumping number | Dimensionless | Dimensionless |
| $p$ | Pressure | Pa | $lbf/in^2$ |
| $q$ | Entrained flow rate | $m^3/s$ | $ft^3/s$ |
| $Q$ | Volumetric flow rate | $m^3/s$ | $ft^3/s$ |
| $Q$ | Throughput (vacuum flow) | $Pa \cdot m^3/s$ | $(lbf/in^2) \cdot ft^3/s$ |
| $\delta Q$ | Heat input per unit mass | J/kg | Btu/lbm |
| $r$ | Radial coordinate | m | ft |
| $R$ | Radius | m | ft |
| $R$ | Ideal gas universal constant | $J/(kgmol \cdot K)$ | $Btu/(lbmol \cdot °R)$ |
| $R_i$ | Volume fraction of phase $i$ | Dimensionless | Dimensionless |
| Re | Reynolds number | Dimensionless | Dimensionless |
| $s$ | Density ratio | Dimensionless | Dimensionless |
| $s$ | Entropy per unit mass | $J/(kg \cdot K)$ | $Btu/(lbm \cdot °R)$ |
| $S$ | Slope | Dimensionless | Dimensionless |
| $S$ | Pumping speed | $m^3/s$ | $ft^3/s$ |
| $S$ | Surface area per unit volume | l/m | l/ft |
| Sr | Strouhal number | Dimensionless | Dimensionless |
| $t$ | Time | s | s |
| $t$ | Force per unit area | Pa | $lbf/in^2$ |
| $T$ | Absolute temperature | K | °R |
| $u$ | Internal energy per unit mass | J/kg | Btu/lbm |
| $u$ | Velocity | m/s | ft/s |
| $U$ | Velocity | m/s | ft/s |
| $\upsilon$ | Velocity | m/s | ft/s |
| $V$ | Velocity | m/s | ft/s |
| $V$ | Volume | $m^3$ | $ft^3$ |
| We | Weber number | Dimensionless | Dimensionless |
| $\dot{W}_s$ | Rate of shaft work | J/s | Btu/s |
| $\delta W_s$ | Shaft work per unit mass | J/kg | Btu/lbm |
| $x$ | Cartesian coordinate | m | ft |
| $y$ | Cartesian coordinate | m | ft |
| $z$ | Cartesian coordinate | m | ft |
| $Z$ | Elevation | m | ft |

Greek Symbols

| | | | |
|---|---|---|---|
| $\alpha$ | Velocity profile factor | Dimensionless | Dimensionless |
| $\alpha$ | Included angle | rad | rad |
| $\beta$ | Velocity profile factor | Dimensionless | Dimensionless |
| $\beta$ | Bulk modulus of elasticity | Pa | $lbf/in^2$ |
| $\dot{\gamma}$ | Shear rate | l/s | l/s |
| $\Gamma$ | Mass flow rate | $kg/(m \cdot s)$ | $lbm/(ft \cdot s)$ |
| $\Gamma_{ij}$ | Components of rate of deformation tensor | 1/s | 1/s |
| $\Gamma$ | Magnitude of rate of deformation tensor | 1/s | 1/s |
| $\delta$ | Boundary layer or film thickness | m | ft |
| $\delta_{ij}$ | Kronecker delta | Dimensionless | Dimensionless |
| $\varepsilon$ | Pipe roughness | m | ft |
| $\varepsilon$ | Void fraction | Dimensionless | Dimensionless |
| $\varepsilon$ | Turbulent dissipation rate | $J/(kg \cdot s)$ | $ft \cdot lbf/(lbm \cdot s)$ |
| $\theta$ | Residence time | s | S |
| $\theta$ | Angle | rad | rad |
| $\lambda$ | Mean free path | m | ft |
| $\mu$ | Viscosity | $Pa \cdot s$ | $lbm/(ft \cdot s)$ |
| $\nu$ | Kinematic viscosity | $m^2/s$ | $ft^2/s$ |
| $\rho$ | Density | $kg/m^3$ | $lbm/ft^3$ |
| $\sigma$ | Surface tension | N/m | lbf/ft |
| $\sigma$ | Cavitation number | Dimensionless | Dimensionless |
| $\sigma_{ij}$ | Components of total stress tensor | Pa | $lbf/in^2$ |
| $\tau$ | Shear stress | Pa | $lbf/in^2$ |
| $\tau$ | Time period | s | s |
| $\tau_{ij}$ | Components of deviatoric stress tensor | Pa | $lbf/in^2$ |
| $\Phi$ | Energy dissipation rate per unit volume | $J/(m^3 \cdot s)$ | $ft \cdot lbf/(ft^3 \cdot s)$ |
| $\phi$ | Angle of inclination | rad | rad |
| $\omega$ | Vorticity | 1/s | 1/s |

*Note that with U.S. Customary System units, the conversion factor $g_c$ may be required to make equations in this section dimensionally consistent; $g_c = 32.17\ (lbm \cdot ft)/(lbf \cdot s^2)$.

## NATURE OF FLUIDS

**Deformation and Stress** A *fluid* is a substance that undergoes continuous deformation when subjected to a shear stress, as illustrated in Fig. 6-1. A fluid is bounded by two large parallel plates, of area $A$, separated by a small distance $H$. The bottom plate is held fixed. Application of a force $F$ to the upper plate causes it to move at velocity $V$. The fluid continues to deform as long as the force is applied, unlike a solid, which would undergo only a finite deformation.

The force per unit area is the shear stress $\tau = F/A$. Within the fluid, a linear velocity profile $u = Vy/H$ is established; because of the *no-slip condition,* the fluid bounding the lower plate has zero velocity and the fluid bounding the upper plate moves at the plate velocity $V$. The velocity gradient $\dot{\gamma} = du/dy$ is the *shear rate* for this flow. Shear rates are usually reported in units of reciprocal seconds. The flow in Fig. 6-1 is a *simple shear flow*.

**Viscosity** The ratio of shear stress to shear rate is the viscosity $\mu$.

$$\mu = \frac{\tau}{\dot{\gamma}} \tag{6-1}$$

The SI units of viscosity are $kg/(m \cdot s)$ or $Pa \cdot s$ (pascal-seconds). The cgs unit for viscosity is the poise (P); 1 $Pa \cdot s$ = 10 P = 1000 centipoise (cP) or 0.672 $lbm/(ft \cdot s)$. The terms *absolute viscosity* and *shear viscosity* are synonymous with the viscosity as used in Eq. (6-1). *Kinematic viscosity* $\nu \equiv \mu/\rho$ is the ratio of viscosity to density. The SI units of kinematic viscosity are $m^2/s$. The cgs unit stoke (St) = 1 $cm^2/s$.

**Rheology** In general, fluid flow patterns are more complex than the one shown in Fig. 6-1, as is the relationship between fluid deformation and stress. Rheology is the discipline of fluid mechanics which studies this relationship. One goal of rheology is to obtain *constitutive equations* by which stresses may be computed. For simplicity, fluids may be classified into rheological types in reference to the simple shear flow of Fig. 6-1. Complete definitions require extension to multidimensional flow. For more information, several good references are available, including R. B. Bird, R. C. Armstrong, and O. Hassager [*Dynamics of Polymeric Liquids*, vol. 1: *Fluid Mechanics*, Wiley, New York, 1977]; H. A. Barnes, J. F. Hutton, and K. Walters [*An Introduction to Rheology*, Elsevier, Amsterdam, 1989], C. W. Macosko [*Rheology Principles, Measurements and Applications*, Wiley-VCH, New York, 1994], and F. A. Morrison [*Understanding Rheology*, Oxford University, Oxford, 2001].

Fluids without elasticity do not undergo any reverse deformation when shear stress is removed, and they are called *purely viscous* fluids. The shear stress depends only on the rate of deformation, and not on the extent of deformation (strain). Those that exhibit both viscous and elastic properties are called *viscoelastic* fluids.

Purely viscous fluids are further classified into time-independent and time-dependent fluids. For time-independent fluids, the shear stress depends on only the instantaneous shear rate. The shear stress for time-dependent fluids depends on the history of the rate of deformation, as a result of structure or orientation buildup or breakdown during deformation.

A *rheogram* is a plot of shear stress versus shear rate for a fluid in simple shear flow. Rheograms for several types of time-independent fluids are shown in Fig. 6-2. The *newtonian* fluid rheogram is a straight line passing through the origin. The slope of the line is the viscosity. For a newtonian fluid, the viscosity is independent of shear rate and depends on temperature and perhaps pressure. By far, the newtonian fluid is the largest class of fluid of engineering importance. Gases and low-molecular-weight liquids are generally newtonian. Newton's law of viscosity is a rearrangement of Eq. (6-1) in which the viscosity is a constant:

$$\tau = \mu\dot{\gamma} = \mu\frac{du}{dy} \tag{6-2}$$

Fluids for which the viscosity varies with shear rate are called *nonnewtonian fluids.* For nonnewtonian fluids the viscosity, defined as the ratio of shear stress to shear rate, is often called the *apparent viscosity* to emphasize the distinction from newtonian behavior. Purely viscous, time-independent fluids, for which the apparent viscosity may be expressed as a function of shear rate, are called *generalized newtonian fluids.*

Nonnewtonian fluids include those for which a finite stress $\tau_y$ is required before continuous deformation occurs; these are called *yield-stress* materials. The *Bingham plastic* fluid is the simplest yield-stress material; its rheogram has a constant slope $\mu_\infty$, called the *infinite shear* viscosity.

$$\tau = \tau_y + \mu_\infty\dot{\gamma} \tag{6-3}$$

Highly concentrated suspensions of fine solid particles frequently exhibit Bingham plastic behavior.

*Shear-thinning* fluids are those for which the slope of the rheogram decreases with increasing shear rate. These fluids have also been called *pseudoplastic,* but this terminology is outdated. Many polymer melts and solutions, as well as some solids suspensions, are shear-thinning. Shear-thinning fluids without yield stresses are often fit to a power law model over a range of shear rates

$$\tau = K\dot{\gamma}^n \tag{6-4}$$

The apparent viscosity is

$$\mu = K\dot{\gamma}^{n-1} \tag{6-5}$$

The factor $K$ is the consistency index or power law coefficient, and $n$ is the power law exponent. The exponent $n$ is dimensionless, while $K$ has units of $kg/(m \cdot s^{2-n})$. For shear-thinning fluids, $n < 1$. The power law model typically provides a good fit to data over a range of one to two orders of magnitude in shear rate; behavior at very low and very high shear rates is often newtonian. Shear-thinning fluids with yield stresses are often fit to the Herschel-Bulkley model, which adds a yield stress to Eq. (6-4). Numerous other rheological model equations for shear-thinning fluids are in common use.

*Dilatant,* or shear-thickening, fluids show increasing viscosity with increasing shear rate. Over a limited range of shear rate, they may be fit to the power law model with $n > 1$. Dilatancy is rare, observed only in certain concentration ranges in some particle suspensions [G. W. Govier and K. Aziz, *The Flow of Complex Mixtures in Pipes*, Krieger, Huntington, N.Y., 1977, pp. 33–34]. Extensive discussions of dilatant suspensions, together with a listing of dilatant systems, are given by R. G. Green and R. G. Griskey [*Trans. Soc. Rheol.* **12**(1): 13–25 (1968)]; R. G. Griskey and R. G. Green [*AIChE J.* **17:** 725–728 (1971)]; and W. H. Bauer and E. A. Collins ["Thixotropy and Dilatancy," in F. R. Eirich, *Rheology,* vol. 4, Academic, New York, 1967].

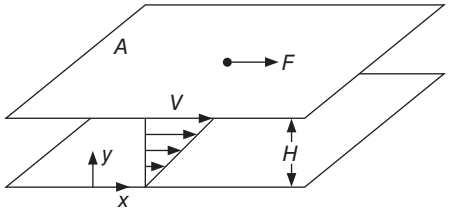

**FIG. 6-1** Deformation of a fluid subjected to a shear stress.

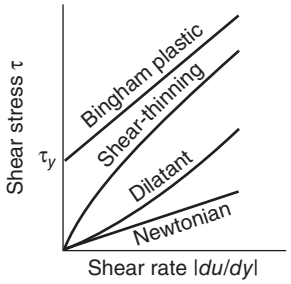

**FIG. 6-2** Shear diagrams.

*Time-dependent* fluids are those for which structural rearrangements occur during deformation at a rate too slow to maintain equilibrium configurations. As a result, shear stress changes with duration of shear. *Thixotropic* fluids, such as mayonnaise, clay suspensions used as drilling muds, and some paints and inks, starting from rest, show decreasing shear stress with time at constant shear rate. A detailed description of thixotropic behavior and a list of thixotropic systems are found in W. H. Bauer and E. A. Collins ["Thixotropy and Dilatancy," in Eirich, *Rheology,* vol. 4, Academic, New York, 1967].

*Rheopectic* behavior is the opposite of thixotropy. Starting from rest, shear stress increases with time at a constant shear rate. Rheopectic behavior has been observed in bentonite sols, vanadium pentoxide sols, and gypsum suspensions in water [W. H. Bauer and E. A. Collins, "Thixotropy and Dilatancy," in Eirich, *Rheology,* vol. 4, Academic, New York, 1967] as well as in some polyester solutions [I. Steg and D. Katz, *J. Appl. Polym. Sci.* **9:** 3, 177 (1965)].

*Viscoelastic* fluids exhibit elastic recovery from deformation when stress is removed. Polymeric liquids comprise the largest group of fluids in this class. A property of viscoelastic fluids is the *relaxation time,* which is a measure of the time required for elastic effects to decay. Viscoelastic effects may be important with sudden changes in rates of deformation, as in flow startup and stop, rapidly oscillating flows, or flow through sudden expansions or contractions. In viscoelastic flows, normal stresses perpendicular to the direction of shear are different from those in the parallel direction. These give rise to such behaviors as the *Weissenberg effect,* in which fluid climbs up a rotating shaft, and *die swell,* where a stream of fluid issuing from a tube may expand to two or more times the tube diameter.

Analysis of viscoelastic flows is very difficult. Simple constitutive equations are unable to describe all the material behavior exhibited by viscoelastic fluids even in geometrically simple flows. More-complex constitutive equations may be more accurate, but become exceedingly difficult to apply, especially for complex geometries, even with advanced numerical methods. For good discussions of viscoelastic fluid behavior, including various types of constitutive equations, see R. B. Bird, R. C. Armstrong, and O. Hassager [*Dynamics of Polymeric Liquids,* vol. 1: *Fluid Mechanics,* Wiley, New York, 1977]; S. Middleman [*The Flow of High Polymers,* Interscience (Wiley), New York, 1968]; or G. Astarita and G. Marrucci [*Principles of Nonnewtonian Fluid Mechanics,* McGraw-Hill, New York, 1974].

*Polymer processing* depends heavily on the flow of nonnewtonian fluids. See the texts by S. Middleman [*Fundamentals of Polymer Processing,* McGraw-Hill, New York, 1977] and Z. Tadmor and C. Gogos [*Principles of Polymer Processing,* Wiley, New York, 1979].

There are a wide variety of instruments for measurement of newtonian viscosity as well as rheological properties of nonnewtonian fluids. They are described in C. W. Macosko [*Rheology Principles, Measurements and Applications,* Wiley-VCH, New York, 1994]; B. D. Coleman et al. [*Viscometric Flows of Nonnewtonian Fluids,* Springer-Verlag, Berlin, 1966]; and J. M. Dealy and K. F. Wissbrun [*Melt Rheology and Its Role in Plastics Processing,* Van Nostrand Reinhold, New York, 1990]. Measurement of rheological behavior requires well-characterized flows. Such *rheometric* flows are thoroughly discussed by G. Astarita and G. Marrucci [*Principles of Nonnewtonian Fluid Mechanics,* McGraw-Hill, New York, 1974].

## KINEMATICS OF FLUID FLOW

**Velocity** *Kinematics* refers to the quantitative description of fluid motion or deformation. The rate of deformation depends on the distribution of velocity within the fluid. Fluid velocity **v** is a vector quantity, with three cartesian components $v_x$, $v_y$, and $v_z$. The velocity vector is a function of spatial position and time. In a *steady* flow, the velocity is independent of time, while in *unsteady* flow **v** varies with time.

**Streamlines, Pathlines, and Streaklines** These are curves in a flow field which provide insight into the flow pattern. *Streamlines* are tangent at every point to the local instantaneous velocity vector. A *pathline* is the path followed by a material element of fluid. *Streaklines* are curves on which are found all the material particles that passed through a particular point in space at some earlier time. For example, a streakline is revealed by releasing smoke or dye at a point in a flow field. For steady flows, the streamlines, pathlines, and streaklines coincide. In two-dimensional incompressible flows, streamlines are contours of the *stream function.*

Many flows of practical importance, such as those in pipes and channels, are treated as *one-dimensional flows.* There is a single direction called the *flow direction;* velocity components perpendicular to this direction either are zero or are considered unimportant. In one type of one-dimensional flow, variations of quantities such as velocity, pressure, density, and temperature are considered only in the flow direction. More generally, one-dimensional flows have only one nonzero velocity component, which depends on only one coordinate direction, and this coordinate direction may or may not be the same as the flow direction.

**Rate of Deformation Tensor** For general three-dimensional flows, where all three velocity components may be important and may vary in all three coordinate directions, the concept of deformation previously introduced is generalized using the rate of deformation tensor $\Gamma = (1/2)[\nabla\mathbf{v} + (\nabla\mathbf{v})^T]$. In cartesian components,

$$\Gamma_{ij} = \frac{1}{2}\left(\frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i}\right) \tag{6-6}$$

where the subscripts $i$ and $j$ refer to the three coordinate directions. Some authors define the deformation rate tensor as twice that given by Eq. (6-6). For multidimensional flows of incompressible newtonian fluids, Eq. (6-2) may be generalized to

$$\boldsymbol{\tau} = 2\mu\Gamma \tag{6-7}$$

with $\tau_{ij}$ the nine components of the viscous stress tensor. For generalized newtonian fluids in multidimensional flow, $\mu$ is a function of a scalar measure of the rate of deformation $\mu = \mu(\Gamma)$, where

$$\Gamma = \sqrt{\frac{1}{2}\Gamma:\Gamma} = \sqrt{\frac{1}{2}\sum_i\sum_j \Gamma_{ij}\Gamma_{ji}} \tag{6-8}$$

The components of the rate of deformation tensor and equations for the scalar $\Gamma$, in cartesian, cylindrical, and spherical coordinates, are found in Table 6-1. The table also provides the viscous stress components of generalized newtonian fluids and the differential balance equations for mass and momentum (see below) in the three coordinate systems.

**Vorticity** The relative motion between two points in a fluid can be decomposed into rigid body rotation and deformation. The rate of deformation tensor has been defined. Deformation includes uniform volumetric expansion (dilatation) and shear. Dilatation vanishes for incompressible flow. Rotation is described in cartesian coordinates by the vorticity tensor $\omega_{ij} = (1/2)[\partial v_i/\partial_{xj} - \partial v_j/\partial x_i]$. A related quantity is the vector of vorticity given by one-half the curl of the velocity. In two-dimensional flow in the *xy* plane, the vorticity $\omega$ is given by

$$\omega = \frac{1}{2}\left(\frac{\partial v_y}{\partial x} - \frac{\partial v_x}{\partial y}\right) \tag{6-9}$$

Here $\omega$ is the magnitude of the vorticity vector, which is directed along the $z$ axis. An *irrotational* flow is one with zero vorticity. Irrotational flows have been widely studied because of their useful mathematical properties and applicability to flow regions where viscous effects may be neglected (*inviscid* flows).

**Laminar and Turbulent Flow** These terms refer to two distinct types of flow. In *laminar flow,* there are smooth streamlines and the fluid velocity components vary smoothly with position and time. The flow described in reference to Fig. 6-1 is laminar. In *turbulent flow,* streamlines are irregular, and the velocity fluctuates chaotically in time and space. For any given flow geometry, a dimensionless *Reynolds number* may be defined for a newtonian fluid as $\mathrm{Re} = LU\rho/\mu$ where $L$ and $U$ are the characteristic length and velocity. Below a critical value of Re the flow is laminar, while above the critical value a transition to turbulent flow begins. The geometry-dependent critical Reynolds number is determined experimentally.

## CONSERVATION EQUATIONS

**Macroscopic and Microscopic Balances** Three laws of physics are fundamental in fluid mechanics: *conservation of mass, conservation of momentum,* and *conservation of energy*. In addition, *conservation of moment of momentum* (angular momentum) and the *entropy inequality* (second law of thermodynamics) have occasional use. The momentum, moment of momentum, and energy conservation laws apply to inertial reference frames. Conservation principles may be applied to control volumes which may be of finite or differential size, resulting in either *algebraic* or *differential* conservation equations, respectively. These are often called *macroscopic* and *microscopic* balance equations.

**Macroscopic Equations** Figure 6-3 shows an arbitrary control volume of finite size $V_a$ bounded by a surface of area $A_a$ with an outwardly directed unit normal vector **n**. The volume is not necessarily fixed in space. Its boundary moves with velocity **w**. The fluid velocity is **v**.

**Mass Balance** Applied to the control volume, the principle of conservation of mass may be written as

$$\frac{d}{dt}\int_{V_a}\rho\, dV + \int_{A_a}\rho(\mathbf{v}-\mathbf{w})\cdot\mathbf{n}\, dA = 0 \tag{6-10}$$

This equation is also known as the *continuity* equation.

**TABLE 6-1 Differential Equations of Motion, Newtonian Stress Constitutive Equation and Rate of Deformation Tensor, in Cartesian, Cylindrical, and Spherical Coordinates**

Continuity Equation $\frac{D\rho}{Dt} = -\rho\nabla\cdot\mathbf{v}$

Cartesian

$$\frac{\partial\rho}{\partial t}+v_x\frac{\partial\rho}{\partial x}+v_y\frac{\partial\rho}{\partial y}+v_z\frac{\partial\rho}{\partial z}=-\rho\left(\frac{\partial v_x}{\partial x}+\frac{\partial v_y}{\partial y}+\frac{\partial v_z}{\partial z}\right)$$

Cylindrical

$$\frac{\partial\rho}{\partial t}+v_r\frac{\partial\rho}{\partial r}+\frac{v_\theta}{r}\frac{\partial\rho}{\partial\theta}+v_z\frac{\partial\rho}{\partial z}=-\rho\left[\frac{1}{r}\frac{\partial}{\partial r}(rv_r)+\frac{1}{r}\frac{\partial v_\theta}{\partial\theta}+\frac{\partial v_z}{\partial z}\right]$$

Spherical

$$\frac{\partial\rho}{\partial t}+v_r\frac{\partial\rho}{\partial r}+\frac{v_\theta}{r}\frac{\partial\rho}{\partial\theta}+\frac{v_\phi}{r\sin\theta}\frac{\partial\rho}{\partial\phi}=-\rho\left[\frac{1}{r^2}\frac{\partial}{\partial r}(r^2v_r)+\frac{1}{r\sin\theta}\frac{\partial}{\partial\theta}(v_\theta\sin\theta)+\frac{1}{r\sin\theta}\frac{\partial v_\phi}{\partial\phi}\right]$$

Cauchy Momentum Equation $\rho\frac{D\mathbf{v}}{Dt} = -\nabla p+\nabla\cdot\boldsymbol{\tau}+\rho\mathbf{g}$

Cartesian

$$\rho\left(\frac{\partial v_x}{\partial t}+v_x\frac{\partial v_x}{\partial x}+v_y\frac{\partial v_x}{\partial y}+v_z\frac{\partial v_x}{\partial z}\right)=-\frac{\partial p}{\partial x}+\frac{\partial\tau_{xx}}{\partial x}+\frac{\partial\tau_{yx}}{\partial y}+\frac{\partial\tau_{zx}}{\partial z}+\rho g_x$$

$$\rho\left(\frac{\partial v_y}{\partial t}+v_x\frac{\partial v_y}{\partial x}+v_y\frac{\partial v_y}{\partial y}+v_z\frac{\partial v_y}{\partial z}\right)=-\frac{\partial p}{\partial y}+\frac{\partial\tau_{xy}}{\partial x}+\frac{\partial\tau_{yy}}{\partial y}+\frac{\partial\tau_{zy}}{\partial z}+\rho g_y$$

$$\rho\left(\frac{\partial v_z}{\partial t}+v_x\frac{\partial v_z}{\partial x}+v_y\frac{\partial v_z}{\partial y}+v_z\frac{\partial v_z}{\partial z}\right)=-\frac{\partial p}{\partial z}+\frac{\partial\tau_{xz}}{\partial x}+\frac{\partial\tau_{yz}}{\partial y}+\frac{\partial\tau_{zz}}{\partial z}+\rho g_z$$

Cylindrical

$$\rho\left(\frac{\partial v_r}{\partial t}+v_r\frac{\partial v_r}{\partial r}+\frac{v_\theta}{r}\frac{\partial v_r}{\partial\theta}-\frac{v_\theta^2}{r}+v_z\frac{\partial v_r}{\partial z}\right)=-\frac{\partial p}{\partial r}+\frac{1}{r}\frac{\partial}{\partial r}(r\tau_{rr})+\frac{1}{r}\frac{\partial\tau_{\theta r}}{\partial\theta}-\frac{\tau_{\theta\theta}}{r}+\frac{\partial\tau_{zr}}{\partial z}+\rho g_r$$

$$\rho\left(\frac{\partial v_\theta}{\partial t}+v_r\frac{\partial v_\theta}{\partial r}+\frac{v_\theta}{r}\frac{\partial v_\theta}{\partial\theta}+\frac{v_rv_\theta}{r}+v_z\frac{\partial v_\theta}{\partial z}\right)=-\frac{1}{r}\frac{\partial p}{\partial\theta}+\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\tau_{r\theta}\right)+\frac{1}{r}\frac{\partial\tau_{\theta\theta}}{\partial\theta}+\frac{\partial\tau_{z\theta}}{\partial z}+\rho g_\theta$$

$$\rho\left(\frac{\partial v_z}{\partial t}+v_r\frac{\partial v_z}{\partial r}+\frac{v_\theta}{r}\frac{\partial v_z}{\partial\theta}+v_z\frac{\partial v_z}{\partial z}\right)=-\frac{\partial p}{\partial z}+\frac{1}{r}\frac{\partial}{\partial r}(r\tau_{rz})+\frac{1}{r}\frac{\partial\tau_{\theta z}}{\partial\theta}+\frac{\partial\tau_{zz}}{\partial z}+\rho g_z$$

Spherical

$$\rho\left(\frac{\partial v_r}{\partial t}+v_r\frac{\partial v_r}{\partial r}+\frac{v_\theta}{r}\frac{\partial v_r}{\partial\theta}+\frac{v_\phi}{r\sin\theta}\frac{\partial v_r}{\partial\phi}-\frac{v_\theta^2+v_\phi^2}{r}\right)=-\frac{\partial p}{\partial r}+\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\tau_{rr}\right)$$
$$+\frac{1}{r\sin\theta}\frac{\partial}{\partial\theta}(\tau_{\theta r}\sin\theta)+\frac{1}{r\sin\theta}\frac{\partial\tau_{\phi r}}{\partial\phi}-\frac{\tau_{\theta\theta}+\tau_{\phi\phi}}{r}+\rho g_r$$

$$\rho\left(\frac{\partial v_\theta}{\partial t}+v_r\frac{\partial v_\theta}{\partial r}+\frac{v_\theta}{r}\frac{\partial v_\theta}{\partial\theta}+\frac{v_\phi}{r\sin\theta}\frac{\partial v_\theta}{\partial\phi}+\frac{v_rv_\theta}{r}-\frac{v_\phi^2\cot\theta}{r}\right)=-\frac{1}{r}\frac{\partial p}{\partial\theta}+\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\tau_{r\theta}\right)$$
$$+\frac{1}{r\sin\theta}\frac{\partial}{\partial\theta}(\tau_{\theta\theta}\sin\theta)+\frac{1}{r\sin\theta}\frac{\partial\tau_{\phi\theta}}{\partial\phi}+\frac{\tau_{r\theta}}{r}-\frac{\cot\theta}{r}\tau_{\phi\phi}+\rho g_\theta$$

$$\rho\left(\frac{\partial v_\phi}{\partial t}+v_r\frac{\partial v_\phi}{\partial r}+\frac{v_\theta}{r}\frac{\partial v_\phi}{\partial\theta}+\frac{v_\phi}{r\sin\theta}\frac{\partial v_\phi}{\partial\phi}+\frac{v_\phi v_r}{r}+\frac{v_\theta v_\phi}{r}\cot\theta\right)=-\frac{1}{r\sin\theta}\frac{\partial p}{\partial\phi}$$
$$+\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\tau_{r\phi}\right)+\frac{1}{r}\frac{\partial\tau_{\theta\phi}}{\partial\theta}+\frac{1}{r\sin\theta}\frac{\partial\tau_{\phi\phi}}{\partial\phi}+\frac{\tau_{r\phi}}{r}+\frac{2\cot\theta}{r}\tau_{\theta\phi}+\rho g_\phi$$

Stress Constitutive Equation for Newtonian and Generalized Newtonian Fluids

$$\boldsymbol{\tau}=2\mu\boldsymbol{\Gamma}-\frac{2}{3}\mu(\nabla\cdot\mathbf{v})\boldsymbol{\delta}=\mu[\nabla\mathbf{v}+(\nabla\mathbf{v})^T]-\frac{2}{3}\mu(\nabla\cdot\mathbf{v})\boldsymbol{\delta}$$

Cartesian

$$\tau_{xx}=\mu\left[2\frac{\partial v_x}{\partial x}-\frac{2}{3}\nabla\cdot\mathbf{v}\right]\quad\tau_{xy}=\tau_{yx}=\mu\left[\frac{\partial v_x}{\partial y}+\frac{\partial v_y}{\partial x}\right]\quad\tau_{xz}=\tau_{zx}=\mu\left[\frac{\partial v_x}{\partial z}+\frac{\partial v_z}{\partial x}\right]$$

$$\tau_{yy}=\mu\left[2\frac{\partial v_y}{\partial y}-\frac{2}{3}\nabla\cdot\mathbf{v}\right]\quad\tau_{zy}=\tau_{yz}=\mu\left[\frac{\partial v_z}{\partial y}+\frac{\partial v_y}{\partial z}\right]\quad\tau_{zz}=\mu\left[2\frac{\partial v_z}{\partial z}-\frac{2}{3}\nabla\cdot\mathbf{v}\right]$$

$$\nabla\cdot\mathbf{v}=\frac{\partial v_x}{\partial x}+\frac{\partial v_y}{\partial y}+\frac{\partial v_z}{\partial z}$$

Cylindrical

$$\nabla\cdot\mathbf{v}=\frac{1}{r}\frac{\partial}{\partial r}(rv_r)+\frac{1}{r}\frac{\partial v_\theta}{\partial\theta}+\frac{\partial v_z}{\partial z}$$

Spherical

$$\tau_{rr}=\mu\left[2\frac{\partial v_r}{\partial r}-\frac{2}{3}\nabla\cdot\mathbf{v}\right]\quad\tau_{r\theta}=\tau_{\theta r}=\mu\left[r\frac{\partial}{\partial r}\left(\frac{v_\theta}{r}\right)+\frac{1}{r}\frac{\partial v_r}{\partial\theta}\right]$$

$$\tau_{r\phi}=\tau_{\phi r}=\mu\left[\frac{1}{r\sin\theta}\frac{\partial v_r}{\partial\phi}+r\frac{\partial}{\partial r}\left(\frac{v_\phi}{r}\right)\right]$$

$$\tau_{\theta\theta}=\mu\left[2\left(\frac{1}{r}\frac{\partial v_\theta}{\partial\theta}+\frac{v_r}{r}\right)-\frac{2}{3}\nabla\cdot\mathbf{v}\right]\quad\tau_{\phi\theta}=\tau_{\theta\phi}=\mu\left[\frac{1}{r\sin\theta}\frac{\partial v_\theta}{\partial\phi}+\frac{\sin\theta}{r}\frac{\partial}{\partial\theta}\left(\frac{v_\phi}{\sin\theta}\right)\right]$$

$$\tau_{\phi\phi}=\mu\left[2\left(\frac{1}{r\sin\theta}\frac{\partial v_\phi}{\partial\phi}+\frac{v_r}{r}+\frac{v_\theta\cot\theta}{r}\right)-\frac{2}{3}\nabla\cdot\mathbf{v}\right]$$

$$\nabla\cdot\mathbf{v}=\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2v_r\right)+\frac{1}{r\sin\theta}\frac{\partial}{\partial\theta}\left(v_\theta\sin\theta\right)+\frac{1}{r\sin\theta}\frac{\partial v_\phi}{\partial\phi}$$

Navier-Stokes Equation $\rho\frac{D\mathbf{v}}{Dt} = -\nabla p+\mu\nabla^2\mathbf{v}+\rho\mathbf{g}$

Cartesian

$$\rho\left(\frac{\partial v_x}{\partial t}+v_x\frac{\partial v_x}{\partial x}+v_y\frac{\partial v_x}{\partial y}+v_z\frac{\partial v_x}{\partial z}\right)=-\frac{\partial p}{\partial x}+\mu\left(\frac{\partial^2v_x}{\partial x^2}+\frac{\partial^2v_x}{\partial y^2}+\frac{\partial^2v_x}{\partial z^2}\right)+\rho g_x$$

$$\rho\left(\frac{\partial v_y}{\partial t}+v_x\frac{\partial v_y}{\partial x}+v_y\frac{\partial v_y}{\partial y}+v_z\frac{\partial v_y}{\partial z}\right)=-\frac{\partial p}{\partial y}+\mu\left(\frac{\partial^2v_y}{\partial x^2}+\frac{\partial^2v_y}{\partial y^2}+\frac{\partial^2v_y}{\partial z^2}\right)+\rho g_y$$

$$\rho\left(\frac{\partial v_z}{\partial t}+v_x\frac{\partial v_z}{\partial x}+v_y\frac{\partial v_z}{\partial y}+v_z\frac{\partial v_z}{\partial z}\right)=-\frac{\partial p}{\partial z}+\mu\left(\frac{\partial^2v_z}{\partial x^2}+\frac{\partial^2v_z}{\partial y^2}+\frac{\partial^2v_z}{\partial z^2}\right)+\rho g_z$$

Cylindrical

$$\rho\left(\frac{\partial v_r}{\partial t}+v_r\frac{\partial v_r}{\partial r}+\frac{v_\theta}{r}\frac{\partial v_r}{\partial\theta}-\frac{v_\theta^2}{r}+v_z\frac{\partial v_r}{\partial z}\right)=-\frac{\partial p}{\partial r}$$
$$+\mu\left[\frac{\partial}{\partial r}\left(\frac{1}{r}\frac{\partial}{\partial r}(rv_r)\right)+\frac{1}{r^2}\frac{\partial^2v_r}{\partial\theta^2}-\frac{2}{r^2}\frac{\partial v_\theta}{\partial\theta}+\frac{\partial^2v_r}{\partial z^2}\right]+\rho g_r$$

$$\rho\left(\frac{\partial v_\theta}{\partial t}+v_r\frac{\partial v_\theta}{\partial r}+\frac{v_\theta}{r}\frac{\partial v_\theta}{\partial\theta}+\frac{v_rv_\theta}{r}+v_z\frac{\partial v_\theta}{\partial z}\right)=-\frac{1}{r}\frac{\partial p}{\partial\theta}$$
$$+\mu\left[\frac{\partial}{\partial r}\left(\frac{1}{r}\frac{\partial}{\partial r}(rv_\theta)\right)+\frac{1}{r^2}\frac{\partial^2v_\theta}{\partial\theta^2}+\frac{2}{r^2}\frac{\partial v_r}{\partial\theta}+\frac{\partial^2v_\theta}{\partial z^2}\right]+\rho g_\theta$$

$$\rho\left(\frac{\partial v_z}{\partial t}+v_r\frac{\partial v_z}{\partial r}+\frac{v_\theta}{r}\frac{\partial v_z}{\partial\theta}+v_z\frac{\partial v_z}{\partial z}\right)=-\frac{\partial p}{\partial z}$$
$$+\mu\left[\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial v_z}{\partial r}\right)+\frac{1}{r^2}\frac{\partial^2v_z}{\partial\theta^2}+\frac{\partial^2v_z}{\partial z^2}\right]+\rho g_z$$

Spherical

$$\rho\left(\frac{\partial v_r}{\partial t}+v_r\frac{\partial v_r}{\partial r}+\frac{v_\theta}{r}\frac{\partial v_r}{\partial\theta}+\frac{v_\phi}{r\sin\theta}\frac{\partial v_r}{\partial\phi}-\frac{v_\theta^2+v_\phi^2}{r}\right)=-\frac{\partial p}{\partial r}$$
$$+\mu\left[\nabla^2v_r-\frac{2v_r}{r^2}-\frac{2}{r^2}\frac{\partial v_\theta}{\partial\theta}-\frac{2}{r^2}v_\theta\cot\theta-\frac{2}{r^2\sin\theta}\frac{\partial v_\phi}{\partial\phi}\right]+\rho g_r$$

$$\rho\left(\frac{\partial v_\theta}{\partial t}+v_r\frac{\partial v_\theta}{\partial r}+\frac{v_\theta}{r}\frac{\partial v_\theta}{\partial\theta}+\frac{v_\phi}{r\sin\theta}\frac{\partial v_\theta}{\partial\phi}+\frac{v_rv_\theta}{r}-\frac{v_\phi^2\cot\theta}{r}\right)=-\frac{1}{r}\frac{\partial p}{\partial\theta}$$
$$+\mu\left[\nabla^2v_\theta+\frac{2}{r^2}\frac{\partial v_r}{\partial\theta}-\frac{v_\theta}{r^2\sin^2\theta}-\frac{2\cos\theta}{r^2\sin^2\theta}\frac{\partial v_\phi}{\partial\phi}\right]+\rho g_\theta$$

$$\rho\left(\frac{\partial v_\phi}{\partial t}+v_r\frac{\partial v_\phi}{\partial r}+\frac{v_\theta}{r}\frac{\partial v_\phi}{\partial\theta}+\frac{v_\phi}{r\sin\theta}\frac{\partial v_\phi}{\partial\phi}+\frac{v_\phi v_r}{r}+\frac{v_\theta v_\phi}{r}\cot\theta\right)=-\frac{1}{r\sin\theta}\frac{\partial p}{\partial\phi}$$
$$+\mu\left[\nabla^2v_\phi-\frac{v_\phi}{r^2\sin^2\theta}+\frac{2}{r^2\sin\theta}\frac{\partial v_r}{\partial\phi}+\frac{2\cos\theta}{r^2\sin^2\theta}\frac{\partial v_\theta}{\partial\phi}\right]+\rho g_\phi$$

$$\nabla^2=\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right)+\frac{1}{r^2\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right)+\frac{1}{r^2\sin^2\theta}\frac{\partial^2}{\partial\phi^2}$$

**TABLE 6-1 Differential Equations of Motion, Newtonian Stress Constitutive Equation and Rate of Deformation Tensor, in Cartesian, Cylindrical, and Spherical Coordinates** (*Continued*)

Rate of deformation tensor $\Gamma = (1/2)[\nabla \mathbf{v} + (\Delta \mathbf{v})^T]$ and its magnitude $\Gamma = \sqrt{\frac{1}{2}\Gamma : \Gamma}$.
The rate of deformation is $\dot{\gamma} = 2\Gamma$.

Cartesian

$$\Gamma_{xx} = \frac{\partial v_x}{\partial x} \qquad \Gamma_{xy} = \Gamma_{yx} = \frac{1}{2}\left(\frac{\partial v_x}{\partial y} + \frac{\partial v_y}{\partial x}\right) \qquad \Gamma_{xz} = \Gamma_{zx} = \frac{1}{2}\left(\frac{\partial v_x}{\partial z} + \frac{\partial v_z}{\partial x}\right)$$

$$\Gamma_{yy} = \frac{\partial v_y}{\partial y} \qquad \Gamma_{zy} = \Gamma_{yz} = \frac{1}{2}\left(\frac{\partial v_z}{\partial y} + \frac{\partial v_y}{\partial z}\right) \qquad \Gamma_{zz} = \frac{\partial v_z}{\partial z}$$

$$(2\Gamma)^2 = 2\left[\left(\frac{\partial v_x}{\partial x}\right)^2 + \left(\frac{\partial v_y}{\partial y}\right)^2 + \left(\frac{\partial v_z}{\partial z}\right)^2\right] + \left[\frac{\partial v_y}{\partial x} + \frac{\partial v_x}{\partial y}\right]^2 + \left[\frac{\partial v_z}{\partial y} + \frac{\partial v_y}{\partial z}\right]^2 + \left[\frac{\partial v_x}{\partial z} + \frac{\partial v_z}{\partial x}\right]^2$$

Cylindrical

$$\Gamma_{rr} = \frac{\partial v_r}{\partial r} \qquad \Gamma_{r\theta} = \Gamma_{\theta r} = \frac{1}{2}\left[r\frac{\partial}{\partial r}\left(\frac{v_\theta}{r}\right) + \frac{1}{r}\frac{\partial v_r}{\partial \theta}\right] \qquad \Gamma_{rz} = \Gamma_{zr} = \frac{1}{2}\left[\frac{\partial v_r}{\partial z} + \frac{\partial v_z}{\partial r}\right]$$

$$\Gamma_{\theta\theta} = \frac{1}{r}\frac{\partial v_\theta}{\partial \theta} + \frac{v_r}{r} \qquad \Gamma_{z\theta} = \Gamma_{\theta z} = \frac{1}{2}\left[\frac{1}{r}\frac{\partial v_z}{\partial \theta} + \frac{\partial v_\theta}{\partial z}\right] \qquad \Gamma_{zz} = \frac{\partial v_z}{\partial z}$$

$$(2\Gamma)^2 = 2\left[\left(\frac{\partial v_r}{\partial r}\right)^2 + \left(\frac{1}{r}\frac{\partial v_\theta}{\partial \theta} + \frac{v_r}{r}\right)^2 + \left(\frac{\partial v_z}{\partial z}\right)^2\right] + \left[r\frac{\partial}{\partial r}\left(\frac{v_\theta}{r}\right) + \frac{1}{r}\frac{\partial v_r}{\partial \theta}\right]^2 + \left[\frac{1}{r}\frac{\partial v_z}{\partial \theta} + \frac{\partial v_\theta}{\partial z}\right]^2 + \left[\frac{\partial v_r}{\partial z} + \frac{\partial v_z}{\partial r}\right]^2$$

Spherical

$$\Gamma_{rr} = \frac{\partial v_r}{\partial r} \qquad \Gamma_{r\theta} = \Gamma_{\theta r} = \frac{1}{2}\left[r\frac{\partial}{\partial r}\left(\frac{v_\theta}{r}\right) + \frac{1}{r}\frac{\partial v_r}{\partial \theta}\right] \qquad \Gamma_{r\phi} = \Gamma_{\phi r} = \frac{1}{2}\left[\frac{1}{r\sin\theta}\frac{\partial v_r}{\partial \phi} + r\frac{\partial}{\partial r}\left(\frac{v_\phi}{r}\right)\right]$$

$$\Gamma_{\theta\theta} = \frac{1}{r}\frac{\partial v_\theta}{\partial \theta} + \frac{v_r}{r} \qquad \Gamma_{\phi\theta} = \Gamma_{\theta\phi} = \frac{1}{2}\left[\frac{1}{r\sin\theta}\frac{\partial v_\theta}{\partial \phi} + \frac{\sin\theta}{r}\frac{\partial}{\partial \theta}\left(\frac{v_\phi}{\sin\theta}\right)\right]$$

$$\Gamma_{\phi\phi} = \frac{1}{r\sin\theta}\frac{\partial v_\phi}{\partial \phi} + \frac{v_r}{r} + \frac{v_\theta \cot\theta}{r}$$

$$(2\Gamma)^2 = 2\left[\left(\frac{\partial v_r}{\partial r}\right)^2 + \left(\frac{1}{r}\frac{\partial v_\theta}{\partial \theta} + \frac{v_r}{r}\right)^2 + \left(\frac{1}{r\sin\theta}\frac{\partial v_\phi}{\partial \phi} + \frac{v_r}{r} + \frac{v_\theta \cot\theta}{r}\right)^2\right] + \left[r\frac{\partial}{\partial r}\left(\frac{v_\theta}{r}\right) + \frac{1}{r}\frac{\partial v_r}{\partial \theta}\right]^2 + \left[\frac{\sin\theta}{r}\frac{\partial}{\partial \theta}\left(\frac{v_\phi}{\sin\theta}\right) + \frac{1}{r\sin\theta}\frac{\partial v_\theta}{\partial \phi}\right]^2 + \left[\frac{1}{r\sin\theta}\frac{\partial v_r}{\partial \phi} + r\frac{\partial}{\partial r}\left(\frac{v_\phi}{r}\right)\right]^2$$

The equations for $(2\Gamma)^2$ are taken from Deen, *Analysis of Transport Phenomena,* 2d ed., Oxford University Press, New York, 2012, p. 241.

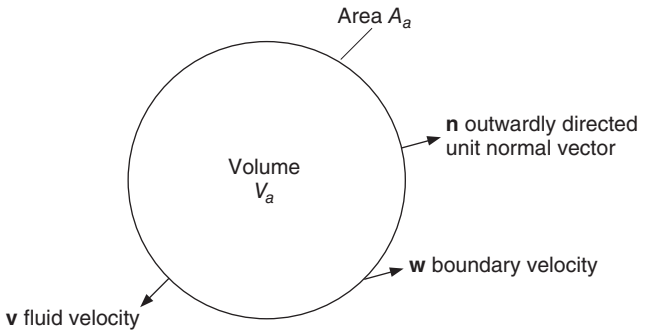

**FIG. 6-3** Arbitrary control volume for application of conservation equations.

Simplified forms of Eq. (6-10) apply to special cases frequently found in practice. For a control volume fixed in space with one inlet of area $A_1$ through which an incompressible fluid enters the control volume at an average velocity $V_1$, and one outlet of area $A_2$ through which fluid leaves at an average velocity $V_2$, as shown in Fig. 6-4, the continuity equation becomes

$$V_1 A_1 = V_2 A_2 \tag{6-11}$$

The average velocity across a surface is given by

$$V = (1/A)\int_A v\, dA \tag{6-12}$$

where $v$ is the local velocity component perpendicular to the surface. The volumetric flow rate $Q$ is the product of average velocity and the cross-sectional area, $Q = VA$. The average *mass velocity* is $G = \rho V$. For steady flows through fixed control volumes with multiple inlets and/or outlets, conservation of mass requires that the sum of inlet mass flow rates equals the sum of outlet mass flow rates. For incompressible flows through fixed control volumes, the sum of inlet flow rates (mass or volumetric) equals the sum of exit flow rates, whether the flow is steady or unsteady.

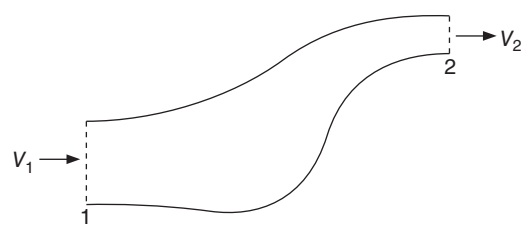

**FIG. 6-4** Fixed control volume with one inlet and one outlet.

**Momentum Balance** Momentum is a vector quantity, and the momentum balance is a vector equation. It (and the energy balance, see below) are written in inertial reference frames. Where gravity is the only body force acting on the fluid, the linear momentum principle, applied to the arbitrary control volume of Fig. 6-3, results in the following expression.

$$\frac{d}{dt}\int_{V_a} \rho \mathbf{v}\, dV + \int_{A_a} \rho \mathbf{v}(\mathbf{v} - \mathbf{w}) \cdot \mathbf{n}\, dA = \int_{V_a} \rho \mathbf{g}\, dV + \int_{A_a} \mathbf{n} \cdot \boldsymbol{\sigma}\, dA \tag{6-13}$$

Here $\mathbf{g}$ is the gravity vector and $\mathbf{n} \cdot \boldsymbol{\sigma}$ is the force per unit area exerted by the surroundings on the fluid in the control volume. The total stress tensor $\sigma$ includes both pressure and viscous stress (see below). For the special case of steady flow at a mass flow rate $\dot{m}$ through a control volume fixed in space with one inlet and one outlet (Fig. 6-4), with the inlet and outlet velocity vectors perpendicular to planar inlet and outlet surfaces, giving average velocity vectors $\mathbf{V}_1$ and $\mathbf{V}_2$, the momentum equation becomes

$$\dot{m}(\beta_2 \mathbf{V}_2 - \beta_1 \mathbf{V}_1) = -p_1 \mathbf{A}_1 - p_2 \mathbf{A}_2 + \mathbf{F} + M\mathbf{g} \tag{6-14}$$

where $M$ is the total mass of fluid in the control volume. The factor $\beta$ arises from the averaging of the velocity across the area of the inlet or outlet surface. It is the ratio of the area average of the square of velocity magnitude to the square of the area average velocity magnitude. For a uniform velocity, $\beta = 1$. For turbulent flow, $\beta$ is nearly unity, while for laminar pipe flow with a parabolic velocity profile, $\beta = 4/3$. Vectors $\mathbf{A}_1$ and $\mathbf{A}_2$ have magnitude equal to the areas of the inlet and outlet surfaces, respectively, and are outwardly directed normal to the surfaces. Vector $\mathbf{F}$ is the force exerted on the fluid by the nonflow boundaries of the control volume. Viscous contributions to the stress vector $\mathbf{n} \cdot \boldsymbol{\sigma}$ are neglected at the inlet and outlet surfaces, leaving only pressure forces there. Equation (6-14) may be generalized to multiple inlets and/or outlets. In such cases, a distinct flow rate $\dot{m}_i$ applies to each inlet or outlet *i*. To generalize the equation, $-p\mathbf{A}$ terms for each inlet and outlet, $-\dot{m}_i \beta_i \mathbf{V}_i$ terms for each inlet, and $\dot{m}_i \beta_i \mathbf{V}_i$ terms for each outlet are included.

Balance equations for angular momentum, or moment of momentum, may also be written. They are used less frequently than the linear momentum equations. See S. Whitaker [*Introduction to Fluid Mechanics,* Krieger, Huntington, N.Y., 1981]; J. O. Wilkes [*Fluid Mechanics for Chemical Engineers,* 2d ed., Prentice-Hall, Upper Saddle River, N.J., 2006]; and N. de Nevers [*Fluid Mechanics for Chemical Engineers,* 3d ed., McGraw-Hill, New York, 2005].

**Total Energy Balance** The total energy balance derives from the first law of thermodynamics. Applied to the arbitrary control volume of Fig. 6-3, it leads to an equation for the rate of change of the sum of internal, kinetic, and gravitational potential energy. Energy input to the control volume

comes from work and heat flux at the boundary. The balance also includes energy input by relatively uncommon volumetric sources such as inductive heating, expressed as energy input per unit volume $Q_V$. In this equation, $u$ is the internal energy per unit mass, $\upsilon$ is the magnitude of the velocity vector $\mathbf{v}$, $Z$ is elevation, $g$ is the gravitational acceleration, and $\mathbf{q}$ is the heat flux vector:

$$\frac{d}{dt}\int_{V_a}\rho\left(u+\frac{v^2}{2}+gZ\right)dV+\int_{A_a}\rho\left(u+\frac{v^2}{2}+gZ\right)(\mathbf{v}-\mathbf{w})\cdot\mathbf{n}\,dA = \int_{A_a}(\mathbf{v}\cdot\mathbf{n}\cdot\boldsymbol{\sigma})\,dA-\int_{A_a}(\mathbf{q}\cdot\mathbf{n})dA+\int_{V_a}Q_V\,dV \tag{6-15}$$

The first integral on the right-hand side is the rate of work done on the fluid in the control volume by forces at the boundary. It includes both work done by moving solid boundaries and work done at flow entrances and exits. The work done by moving solid boundaries also includes that by surfaces such as pump impellers; this work is called *shaft work*; its rate is $\dot{W}_S$.

A useful simplification of the total energy equation applies to a particular set of assumptions. These are a control volume with fixed solid boundaries, except for those producing shaft work, steady-state conditions, and mass flow at a rate $\dot{m}$ through a single planar entrance and a single planar exit (Fig. 6-4), to which the velocity vectors are perpendicular and $Q_V = 0$. As with Eq. (6-14), viscous contributions to the stress vector $\mathbf{n}\cdot\boldsymbol{\sigma}$ are neglected at the entrance and exit surfaces.

$$h_1+\alpha_1\frac{V_1^2}{2}+gz_1=h_2+\alpha_2\frac{V_2^2}{2}+gz_2-\delta Q-\delta W_S \tag{6-16}$$

Here $h$ is the enthalpy per unit mass, $h = u + p/\rho$. The shaft work per unit of mass flowing through the control volume is $\delta W_S = \dot{W}_S/\dot{m}$. Similarly, $\delta Q$ is the heat input per unit of mass. The factor $\alpha$ is the ratio of the cross-sectional area average of the cube of the velocity to the cube of the average velocity. For a uniform velocity profile, $\alpha = 1$. In turbulent flow, $\alpha$ is usually assumed to equal unity; in turbulent pipe flow, it is typically about 1.07. For laminar flow in a circular pipe with a parabolic velocity profile, $\alpha = 2$.

**Mechanical Energy Balance, Bernoulli Equation** A balance equation for the sum of kinetic and potential energy may be obtained from the momentum balance by forming the scalar product with the velocity vector. The resulting equation, called the mechanical energy balance, contains a term accounting for the dissipation of mechanical energy into thermal energy by viscous forces. It is also derivable from the total energy equation in a way that reveals the relationship between the dissipation and entropy generation. The macroscopic mechanical energy balance for the arbitrary control volume of Fig. 6-3 may be written, with $p$ = thermodynamic pressure, as

$$\frac{d}{dt}\int_{V_a}\rho\left(\frac{v^2}{2}+gZ\right)dV+\int_{A_a}\rho\left(\frac{v^2}{2}+gZ\right)(\mathbf{v}-\mathbf{w})\cdot\mathbf{n}\,dA = \int_{V_a}p\nabla\cdot\mathbf{v}\,dV+\int_{A_a}(\mathbf{v}\cdot\mathbf{n}\cdot\boldsymbol{\sigma})dA-\int_{V_a}\Phi dV \tag{6-17}$$

The last term is the rate of viscous energy dissipation to internal energy, also called the rate of viscous losses. These losses are the origin of frictional pressure drop in fluid flow. S. Whitaker [*Introduction to Fluid Mechanics*, Krieger, Huntington N.Y., 1981]; R. B. Bird, W. E. Stewart, and E. N. Lightfoot [*Transport Phenomena,* 2d ed., Wiley, New York, 2002]; and W. M. Deen [*Analysis of Transport Phenomena*, 2d ed., Oxford University Press, Oxford, UK, 2012] provide expressions for the dissipation function $\Phi$ for newtonian fluids in terms of the local velocity gradients. However, when one is using macroscopic balance equations, the local velocity field within the control volume is usually unknown. For such cases additional information, which may come from empirical correlations, is needed.

For the same special conditions as for Eq. (6-16), except for the $Q_V = 0$ restriction, the mechanical energy equation reduces to

$$\alpha_1\frac{V_1^2}{2}+gZ_1+\delta W_S=\alpha_2\frac{V_2^2}{2}+gZ_2+\int_{p_1}^{p_2}\frac{dp}{\rho}+l_v \tag{6-18}$$

Here $l_v$ is the energy dissipation per unit mass. This equation has been called the *engineering Bernoulli equation.* For an incompressible flow, Eq. (6-18) becomes

$$\frac{p_1}{\rho}+\alpha_1\frac{V_1^2}{2}+gZ_1+\delta W_S=\frac{p_2}{\rho}+\alpha_2\frac{V_2^2}{2}+gZ_2+l_v \tag{6-19}$$

The Bernoulli equation can be written for incompressible, inviscid flow along a streamline:

$$\frac{p_1}{\rho}+\frac{V_1^2}{2}+gZ_1=\frac{p_2}{\rho}+\frac{V_2^2}{2}+gZ_2 \tag{6-20}$$

Unlike the momentum equation, Eq. (6-14), the Bernoulli equation does not generalize to multiple inlets or outlets by mere addition of terms.

**Microscopic Balance Equations** Partial differential balance equations express the conservation principles at a point in space. The two most used equations, for mass and momentum, are presented here.

**Mass Balance, Continuity Equation** The continuity equation, expressing conservation of mass, may be written in vector notation as

$$\frac{\partial\rho}{\partial t}+\nabla\cdot(\rho\mathbf{v})=0 \tag{6-21}$$

In terms of the *substantial derivative,* $D/Dt = \partial/\partial t + \mathbf{v}\cdot\nabla$,

$$\frac{D\rho}{Dt}=-\rho\nabla\cdot\mathbf{v} \tag{6-22}$$

Also called the *material derivative,* $D/Dt$ is the rate of change in a lagrangian reference frame, that is, following a material particle. For incompressible flow,

$$\nabla\cdot\mathbf{v}=0 \tag{6-23}$$

Equation (6-22) in cartesian, cylindrical, and spherical coordinates may be found in Table 6-1.

**Stress Tensor** The stress tensor is needed to completely describe the stress state for microscopic momentum balances in multidimensional flows. The components of the stress tensor $\sigma_{ij}$ give the force in the $j$ direction on a plane perpendicular to the $i$ direction, using a sign convention defining a positive stress as one where the fluid with the greater $i$ coordinate value exerts a force in the positive $j$ direction on the fluid with the lesser $i$ coordinate. Several references in fluid mechanics and continuum mechanics provide discussions, to various levels of detail, of stress in a fluid, e.g., R. Aris [*Vectors, Tensors and the Basic Equations of Fluid Mechanics*, Dover, New York, 1962]; W. M. Deen [*Analysis of Transport Phenomena*, 2d ed., Oxford University Press, Oxford, UK, 2012]; and J. C. Slattery [*Advanced Transport Phenomena*, Cambridge University Press, Cambridge, UK, 1999].

The stress has an isotropic contribution due to fluid pressure and a *deviatoric* contribution due to viscous deformation. The total stress is

$$\boldsymbol{\sigma}=-p\boldsymbol{\delta}+\boldsymbol{\tau} \tag{6-24}$$

where $p$ is the pressure. The deviatoric stress for a newtonian fluid is

$$\boldsymbol{\tau}=2\mu\Gamma+\left(\kappa-\frac{2}{3}\mu\right)(\nabla\cdot\mathbf{v})\,\boldsymbol{\delta} \tag{6-25}$$

The identity tensor components $\delta_{ij}$ are zero for $i \neq j$ and unity for $i = j$. There is uncertainty about the value of the *bulk viscosity* $\kappa$. Traditionally, Stokes' hypothesis, $\kappa = 0$, has been invoked. For incompressible flow, the value of bulk viscosity is immaterial as Eq. (6-25) reduces to Eq. (6-7).

Similar generalizations to multidimensional flow are necessary for nonnewtonian constitutive equations. The components of the stress constitutive equation in cartesian, cylindrical, and spherical coordinates for newtonian and generalized newtonian fluids are shown in Table 6-1.

**Cauchy Momentum and Navier-Stokes Equations** The differential equation for conservation of momentum is called the Cauchy momentum equation.

$$\rho\frac{D\mathbf{v}}{Dt}=\rho\left[\frac{\partial\mathbf{v}}{\partial t}+\mathbf{v}\cdot\nabla\mathbf{v}\right]=-\nabla p+\nabla\cdot\boldsymbol{\tau}+\rho\mathbf{g} \tag{6-26}$$

For an incompressible newtonian fluid with constant viscosity, substitution of Eqs. (6-7) and (6-6) into Eq. (6-26) gives the *Navier-Stokes equation*

$$\rho\frac{D\mathbf{v}}{Dt}=\rho\left[\frac{\partial\mathbf{v}}{\partial t}+\mathbf{v}\cdot\nabla\mathbf{v}\right]=-\nabla p+\mu\nabla^2\mathbf{v}+\rho\mathbf{g} \tag{6-27}$$

The pressure and gravity terms in Eq. (6-27) may be combined by replacing the pressure $p$ by the equivalent pressure $P = p + \rho gZ$, where $Z$ is elevation. The left-hand side terms of the Navier-Stokes equation are the *inertial terms,* while the terms including viscosity $\mu$ are the *viscous terms.* Limiting cases under which the Navier-Stokes equations may be simplified include *creeping flows* in which the inertial terms are neglected, *inviscid flows* in which the viscous terms are neglected, and *boundary layer* and *lubrication* flows in which certain terms are neglected based on scaling arguments. Creeping flows are described by J. Happel and H. Brenner [*Low Reynolds Number Hydrodynamics,* Prentice-Hall, Englewood Cliffs, N.J., 1965] and L. G. Leal [*Advanced Transport Phenomena*, Cambridge University Press, Cambridge, UK, 2007]; inviscid flows by H. Lamb [*Hydrodynamics,* 6th ed., Dover, New York, 1945] and L. M. Milne-Thompson [*Theoretical Hydrodynamics,* 5th ed., Macmillan, New York, 1968]; boundary layer theory by H. Schlichting and K. Gersten [*Boundary Layer Theory,* 8th ed rev., Springer-Verlag, Berlin, 2003] and lubrication theory by G. K. Batchelor [*An Introduction to Fluid Dynamics,* Cambridge University, Cambridge, UK, 1967], M. M. Denn [*Process Fluid Mechanics,* Prentice-Hall, Englewood Cliffs, N.J., 1979], and

W. M. Deen [*Analysis of Transport Phenomena*, 2d ed., Oxford University Press, Oxford, UK, 2012].

Because the Navier-Stokes equations are first-order in pressure and second-order in velocity, their solution requires one pressure boundary condition and two velocity boundary conditions ( for each velocity component) to completely specify the solution for a steady flow. The *no-slip* condition, which requires that the fluid velocity equal the velocity of any bounding solid surface, occurs in most problems. Specification of velocity is a type of boundary condition sometimes called a *Dirichlet condition.* Often boundary conditions involve stresses, and thus velocity gradients, rather than the velocities themselves. Specification of velocity derivatives is a *Neumann condition.* For example, at the boundary between a viscous liquid and a gas, it is often assumed that the liquid shear stresses are zero. In numerical solution of the Navier-Stokes equations, Dirichlet and Neumann, or *essential* and *natural,* boundary conditions may be satisfied by different means.

*Fluid statics,* discussed in Sec. 10 in reference to pressure measurement, is the branch of fluid mechanics in which the fluid velocity either is zero or is uniform and constant relative to an inertial reference frame. With velocity gradients equal to zero, the momentum equation reduces to a simple expression for the pressure field, $\nabla p = \rho \mathbf{g}$. Letting $z$ be directed vertically upward, so that $g_z = -g$ where $g$ is the gravitational acceleration (9.807 m/s$^2$ or 32.17 ft/s$^2$), the pressure field is given by

$$\frac{dp}{dz} = -\rho g \tag{6-28}$$

This equation applies to any incompressible or compressible static fluid. For an incompressible liquid, pressure varies linearly with depth.

The *force exerted on a submerged planar surface* of area $A$ is given by $F = p_c A$ where $p_c$ is the pressure at the geometric *centroid* of the surface. The *center of pressure,* the point of application of the net force, is always lower than the centroid. For details see, for example, I. H. Shames [*Mechanics of Fluids,* 3d ed., McGraw-Hill, New York, 1992] where may also be found discussion of forces on *curved surfaces*, *buoyancy*, and *stability of floating bodies.*

**Examples** Four examples follow, illustrating the application of the conservation equations.

***Example 6-1 Force Exerted on a Reducing Bend*** An incompressible fluid flows through a reducing elbow (Fig. 6-5) situated in a horizontal plane. The inlet velocity $V_1$ is given, and pressures $p_1$ and $p_2$ are measured. By selecting the inlet and outlet surfaces 1 and 2 as shown, the continuity equation, Eq. (6-11), can be used to find the exit velocity $V_2 = V_1 A_1 / A_2$. The mass flow rate is obtained by $\dot{m} = \rho V_1 A_1$.

Assume that the velocity profile is nearly uniform so that $\beta$ is approximately unity. The force exerted on the fluid by the bend has $x$ and $y$ components; these can be found from Eq. (6-14). The $x$ component gives

$$F_x = \dot{m}(V_{2x} - V_{1x}) + p_1 A_{1x} + p_2 A_{2x}$$

while the $y$ component gives

$$F_y = \dot{m}(V_{2y} - V_{1y}) + p_1 A_{1y} + p_2 A_{2y}$$

The velocity components are $V_{1x} = V_1$, $V_{1y} = 0$, $V_{2x} = V_2 \cos\theta$, and $V_{2y} = V_2 \sin\theta$. The area vector components are $A_{1x} = -A_1$, $A_{1y} = 0$, $A_{2x} = A_2 \cos\theta$, and $A_{2y} = A_2 \sin\theta$. Therefore, the force components may be calculated from

$$F_x = \dot{m}(V_2 \cos\theta - V_1) - p_1 A_1 + p_2 A_2 \cos\theta$$
$$F_y = \dot{m} V_2 \sin\theta + p_2 A_2 \sin\theta$$

The force acting on the fluid is **F;** the force exerted by the fluid on the bend is **–F.**

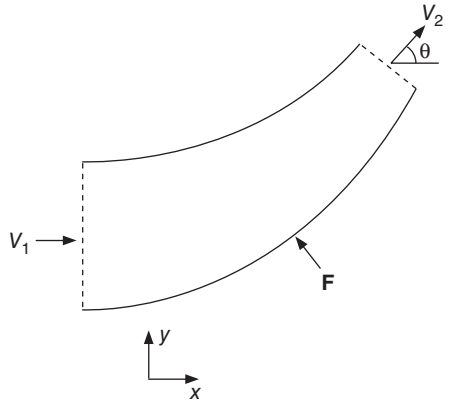

**FIG. 6-5** Force at a reducing bend. **F** is the force exerted by the bend on the fluid. The force exerted by the fluid on the bend is **–F.**

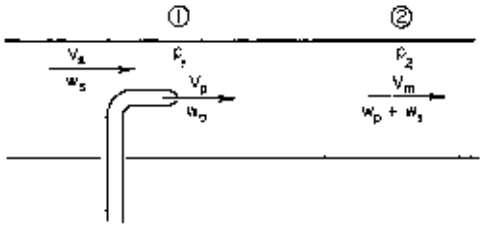

**FIG. 6-6** Simplified ejector.

***Example 6-2 Simplified Ejector*** Figure 6-6 shows a very simplified sketch of an ejector, a device that uses a high-velocity primary fluid to pump another (secondary) fluid. The continuity and momentum equations may be applied on the control volume with inlet and outlet surfaces 1 and 2, as indicated in the figure. The cross-sectional area is uniform, $A_1 = A_2 = A$. Let the mass flow rates and velocities of the primary and secondary fluids be $\dot{m}_p$, $\dot{m}_s$, $V_p$, and $V_s$. Assume for simplicity that the density is uniform. Conservation of mass gives $\dot{m}_2 = \dot{m}_p + \dot{m}_s$. The exit velocity is $V_2 = \dot{m}_2 / (\rho A)$. The principal momentum exchange in the ejector occurs between the two fluids. Relative to this exchange, the force exerted by the walls of the device is small. Therefore, the force term $F$ is neglected from the momentum equation. Written in the flow direction, assuming uniform velocity profiles, and using the extension of Eq. (6-14) for multiple inlets, it gives the pressure rise developed by the device:

$$(p_2 - p_1)A = (\dot{m}_p + \dot{m}_s)V_2 - \dot{m}_p V_p - \dot{m}_s V_s$$

Application of the momentum equation to ejectors of other types is discussed in C. E. Lapple (*Fluid and Particle Dynamics,* University of Delaware, Newark, 1951) and in Sec. 10 of this handbook.

***Example 6-3 Venturi Flowmeter*** An incompressible fluid flows through the venturi flowmeter in Fig. 6-7. An equation is needed to relate the flow rate $Q$ to the pressure drop measured by the manometer. This problem can be solved using the mechanical energy balance. In a well-made venturi, viscous losses are negligible, the pressure drop is the result of acceleration into the throat, and the flow rate predicted neglecting losses is quite accurate. The inlet area is $A$ and the throat area is $a$. Gravity may be neglected even if the venturi is not horizontal, due to the small elevation change.

With control surfaces at 1 and 2 as shown in the figure, Eq. (6-19) in the absence of losses and shaft work gives

$$\frac{p_1}{\rho} + \frac{V_1^2}{2} = \frac{p_2}{\rho} + \frac{V_2^2}{2}$$

The continuity equation gives $V_2 = V_1 A / a$, and $V_1 = Q/A$. The pressure drop measured by the manometer is $p_1 - p_2 = (\rho_m - \rho) g \Delta Z$. By substituting these relations into the energy balance and rearranging, the desired expression for the flow rate is found.

$$Q = \frac{1}{A}\sqrt{\frac{2(\rho_m - \rho) g \Delta Z}{\rho[(A/a)^2 - 1]}}$$

***Example 6-4 Plane Poiseuille Flow*** Driven by a pressure gradient, an incompressible newtonian fluid with constant viscosity flows at a steady rate in the $x$ direction between two very large stationary plates, as shown in Fig. 6-8. The flow is laminar. Cartesian coordinates are used for this rectangular geometry. The *fully developed* velocity profile is to be found. This is the velocity field in the region sufficiently far from the inlet and exit that the velocity is independent of $x$.

This problem requires use of the microscopic balance equations because the velocity is to be determined as a function of position. The boundary conditions result from the no-slip condition. All three velocity components must be zero at the plate surfaces $y = H/2$ and $y = -H/2$.

For fully developed flow, all velocity derivatives in the $x$ direction vanish. Since the flow field is infinite in the $z$ direction, all velocity derivatives in the $z$ direction are zero. Therefore, velocity components are a function of $y$ alone. It is also assumed that there is

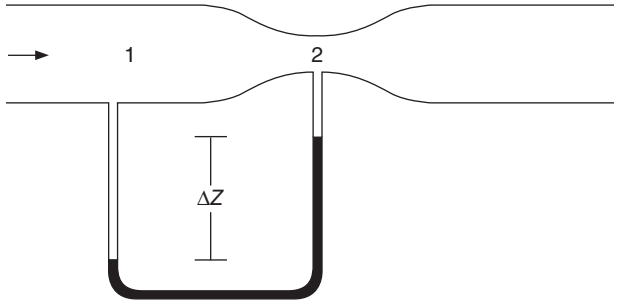

**FIG. 6-7** Venturi flowmeter.

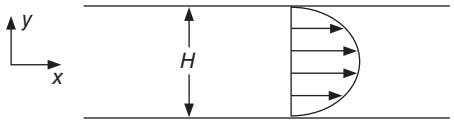

**FIG. 6-8** Plane Poiseuille flow.

no flow in the $z$ direction, so $\upsilon_z = 0$. The continuity equation from Table 6-1, with $\upsilon_z = 0$ and $\partial\upsilon_x/\partial_x = 0$, reduces to

$$\frac{dv_y}{dy} = 0$$

Since $\upsilon_y = 0$ at $y = \pm H/2$, the continuity equation integrates to $\upsilon_y = 0$. This is a direct result of the assumption of fully developed flow. The only nonzero velocity component is $v_x$, and it is a function only of $y$. The flow is one-dimensional.

The Navier-Stokes equations are greatly simplified with $\upsilon_y$, $\upsilon_z$, $\partial\upsilon_x/\partial x$, $\partial\upsilon_x/\partial z$, and $\partial\upsilon_x/\partial t$ all being zero. The three cartesian components from Table 6-1 are written in terms of the equivalent pressure $P$:

$$0 = -\frac{\partial P}{\partial x} + \mu\frac{\partial^2 v_x}{\partial y^2}$$

$$0 = -\frac{\partial P}{\partial y}$$

$$0 = -\frac{\partial P}{\partial z}$$

The latter two equations require that $P$ be a function only of $x$, and therefore $\partial P/\partial x = dP/dx$. Inspection of the first equation then shows one term that is a function of only $x$ and one that is a function of only $y$. This requires that both terms be constant. The pressure gradient $-dP/dx$ is constant. The $x$-component equation becomes

$$\frac{d^2 v_x}{dy^2} = \frac{1}{\mu}\frac{dP}{dx}$$

Two integrations give

$$v_x = \frac{1}{2\mu}\frac{dP}{dx}y^2 + C_1 y + C_2$$

The integration constants $C_1$ and $C_2$ are evaluated from the boundary conditions $\upsilon_x = 0$ at $y = \pm H/2$. The result is

$$v_x = \frac{H^2}{8\mu}\left(-\frac{dP}{dx}\right)\left[1 - \left(\frac{2y}{H}\right)^2\right]$$

This is a *parabolic* velocity distribution. The average velocity $V = (1/H)\int_{-H/2}^{H/2} v_x\, dy$ is

$$V = \frac{H^2}{12\mu}\left(-\frac{dP}{dx}\right)$$

## INCOMPRESSIBLE FLOW IN PIPES AND CHANNELS

**Mechanical Energy Balance** The mechanical energy balance, Eq. (6-19), for *fully developed* incompressible flow in a straight circular pipe of constant diameter $D$ reduces to

$$\frac{p_1}{\rho} + gZ_1 = \frac{p_2}{\rho} + gZ_2 + l_v \tag{6-29}$$

In terms of the equivalent pressure $P = p + \rho gZ$,

$$P_1 - P_2 = \rho l_v \tag{6-30}$$

The pressure drop due to frictional losses $l_v$ is proportional to pipe length $L$ for fully developed flow and may be denoted as the (positive) quantity $\Delta P \equiv P_1 - P_2$.

**Friction Factor and Reynolds Number** For a newtonian fluid in a smooth pipe, dimensional analysis relates the frictional pressure drop per unit length $\Delta P/L$ to the pipe diameter $D$, density $\rho$, viscosity $\mu$, and average velocity $V$ through two dimensionless groups, the *Fanning friction factor* $f$ and the *Reynolds number* Re.

$$f \equiv \frac{D\Delta P}{2\rho V^2 L} \tag{6-31}$$

$$\mathrm{Re} \equiv \frac{DV\rho}{\mu} \tag{6-32}$$

For smooth pipe, the friction factor is a function of only the Reynolds number. In rough pipe, the relative roughness $\varepsilon/D$ also affects the friction factor. Figure 6-9 plots $f$ as a function of Re and $\varepsilon/D$. Values of $\varepsilon$ for various

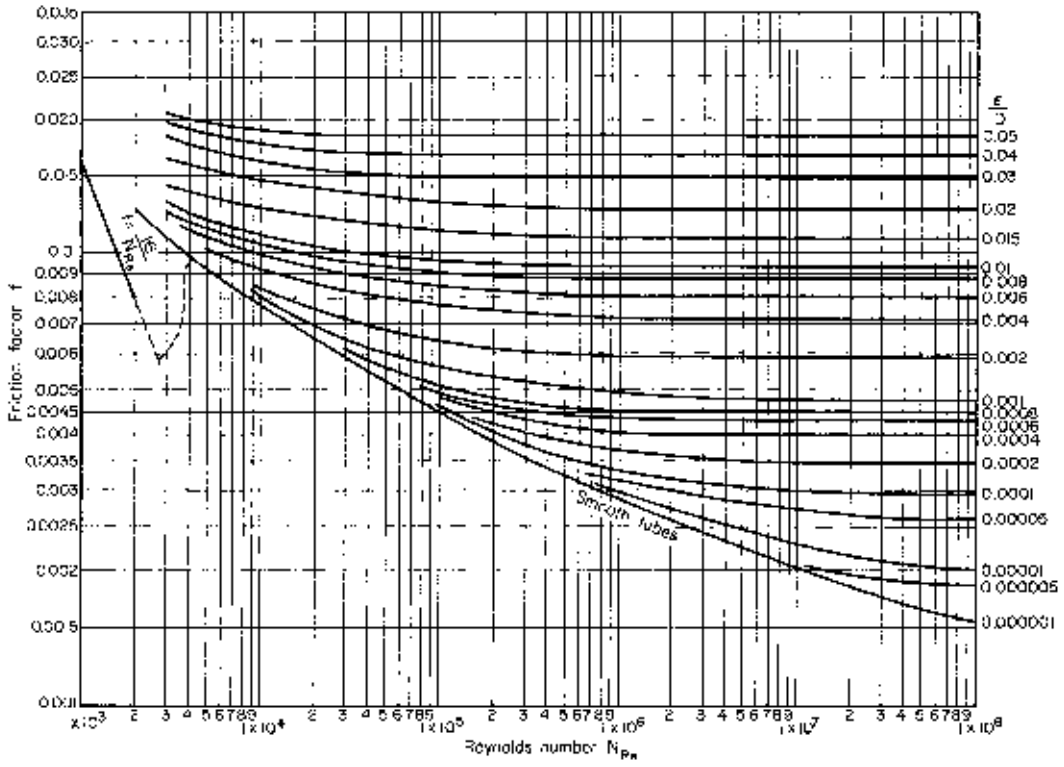

**FIG. 6-9** Fanning friction factors. Reynolds number Re = $DV\rho/\mu$, where $D$ = pipe diameter, $V$ = velocity, $\rho$ = fluid density, and $\mu$ = fluid viscosity. [Based on L. F. Moody, *Trans. ASME*, **66:** 671 (1944).]

**TABLE 6-2 Values of Surface Roughness for Various Materials***

| Material | Surface roughness ε, mm |
|---|---|
| Drawn tubing (brass, lead, glass, and the like) | 0.00152 |
| Commercial steel or wrought iron | 0.0457 |
| Asphalted cast iron | 0.122 |
| Galvanized iron | 0.152 |
| Cast iron | 0.259 |
| Wood stave | 0.183–0.914 |
| Concrete | 0.305–3.05 |
| Riveted steel | 0.914–9.14 |

*From Moody, *Trans. Am. Soc. Mech. Eng.* **66:** 671–684 (1944); *Mech. Eng.* **69:** 1005–1006 (1947). Additional values of ε for various types or conditions of concrete wrought-iron, welded steel, riveted steel, and corrugated-metal pipes are given in Brater and King, *Handbook of Hydraulics,* 6th ed., McGraw-Hill, New York, 1976, pp. 6-12–6-13. To convert millimeters to feet, multiply by $3.281 \times 10^{-3}$.

materials are given in Table 6-2. The Fanning friction factor should not be confused with the Darcy friction factor used by L. F. Moody [*Trans. ASME,* **66:** 671 (1944)], which is four times greater. The Darcy-Weisbach equation is equivalent to Eq. (6-31). Using the momentum equation, the stress at the wall of the pipe may be expressed in terms of the friction factor:

$$\tau_w = f\frac{\rho V^2}{2} \tag{6-33}$$

**Laminar and Turbulent Flow** Below a *critical Reynolds number* of about 2100, the flow is laminar; over the range 2100 < Re < 5000 there is a transition to turbulent flow. Reliable correlations for the friction factor in transitional flow are not available. For laminar flow, the Hagen-Poiseuille equation

$$f = \frac{16}{\mathrm{Re}} \quad \mathrm{Re} \le 2100 \tag{6-34}$$

may be derived from the Navier-Stokes equation and is in excellent agreement with experimental data. It may be rewritten in terms of volumetric flow rate $Q = V\pi D^2/4$ as

$$Q = \frac{\pi \Delta P D^4}{128\mu L} \quad \mathrm{Re} \le 2100 \tag{6-35}$$

For turbulent flow in smooth tubes, the Blasius equation gives the friction factor accurately for a wide range of Reynolds number.

$$f = \frac{0.079}{\mathrm{Re}^{0.25}} \quad 4000 < \mathrm{Re} < 10^5 \tag{6-36}$$

The Colebrook formula [C. F. Colebrook, *J. Inst. Civ. Eng.* (*London*), **11:** 133–156 (1938–39)] gives a good approximation for the *f*-Re-(ε/*D*) data for rough pipes over the entire turbulent flow range:

$$\frac{1}{\sqrt{f}} = -4\log\left[\frac{\varepsilon}{3.7D} + \frac{1.256}{\mathrm{Re}\sqrt{f}}\right] \quad \mathrm{Re} > 4000 \tag{6-37}$$

Equation (6-37) was used to construct the curves in the turbulent flow regime in Fig. 6-9. An equation by S. W. Churchill [*Chem. Eng.* **84**(24): 91–92 (Nov. 7, 1977)] closely approximating the Colebrook formula offers the advantage of being explicit in *f:*

$$\frac{1}{\sqrt{f}} = -4\log\left[\frac{0.27\varepsilon}{D} + \left(\frac{7}{\mathrm{Re}}\right)^{0.9}\right] \quad \mathrm{Re} > 4000 \tag{6-38}$$

Churchill also provided a single equation that may be used for Reynolds numbers in laminar, transitional, and turbulent flow, closely fitting $f = 16/\mathrm{Re}$ in the laminar regime and the Colebrook formula in the turbulent regime, and giving reasonable values in the transition regime, where the friction factor is uncertain.

$$f = 2\left[\left(\frac{8}{\mathrm{Re}}\right)^{12} + \frac{1}{(A+B)^{3/2}}\right]^{1/12}$$

where

$$A = \left[2.457\ln\frac{1}{(7/\mathrm{Re})^{0.9} + 0.27\varepsilon/D}\right]^{16} \tag{6-39}$$

and

$$B = \left(\frac{37{,}530}{\mathrm{Re}}\right)^{16}$$

In laminar flow, *f* is independent of ε/*D*. In turbulent flow, the friction factor for rough pipe follows the smooth tube curve for a range of Reynolds numbers (hydraulically smooth flow). For greater Reynolds numbers, *f* deviates from the smooth pipe curve, eventually becoming independent of Re. This region, often called *complete turbulence,* is frequently encountered in commercial pipe flows.

Two common pipe flow problems are calculation of pressure drop given the flow rate (or velocity) and calculation of flow rate (or velocity) given the pressure drop. When the flow rate is given, the Reynolds number may be calculated directly to determine the flow regime, so that the appropriate relations between *f* and Re can be selected. When the flow rate is specified and the flow is turbulent, Eq. (6-38), being explicit in *f,* may be preferable to Eq. (6-37), which is implicit in *f* and pressure drop.

When the pressure drop is given and the velocity and flow rate are to be determined, the Reynolds number cannot be computed directly, since the velocity is unknown. For such problems, it is useful to note that $\mathrm{Re}\sqrt{f} = (D^{3/2}/\mu)\sqrt{\rho\Delta P/(2L)}$, appearing in the Colebrook equation (6-37), does not include velocity and so can be computed directly, so that *f* may be computed without iteration. Thus Eq. (6-37) is preferable to Eq. (6-38) or Eq. (6-39) when the pressure drop is given.

**Velocity Profiles** In laminar flow, the solution of the Navier-Stokes equation, corresponding to the Hagen-Poiseuille equation, gives the velocity *v* as a function of radial position *r* in a circular pipe of radius *R* in terms of the average velocity $V = Q/A$. The *parabolic* profile, with centerline velocity twice the average velocity, is shown in Fig. 6-10.

$$v = 2V\left(1 - \frac{r^2}{R^2}\right) \tag{6-40}$$

In turbulent flow, the velocity profile is more blunt, with a lower velocity gradient near the center and a steeper gradient near the wall. The region near the wall is described by a *universal* velocity profile, characterized by a *viscous sublayer,* a *buffer zone,* and a *turbulent core.*

Viscous sublayer

$$u_+ = y_+ \qquad \text{for} \qquad y_+ < 5 \tag{6-41}$$

Buffer zone

$$u_+ = 5.00\ln y_+ - 3.05 \qquad \text{for} \qquad 5 < y_+ < 30 \tag{6-42}$$

Turbulent core

$$u_+ = 2.5\ln y_+ + 5.5 \qquad \text{for} \qquad y_+ > 30 \tag{6-43}$$

Here, $u_+ = v/u_*$ is the dimensionless, time-averaged axial velocity, $u_* = \sqrt{\tau_w/\rho}$ is the *friction velocity,* and $\tau_w = f\rho V^2/2$ is the wall stress. The friction velocity is of the order of the root mean square velocity fluctuation perpendicular to the wall in the turbulent core. The dimensionless distance from the wall is $y_+ = yu_*\rho/\mu$. At sufficient Re, the universal velocity profile is valid in the wall region for any cross-sectional channel shape. For incompressible flow in constant-diameter circular pipes, $\tau_w = D\Delta P/4L$ where $\Delta P$ is the equivalent pressure drop in length *L*.

For rough pipes, the velocity profile in the turbulent core is given by

$$u_+ = 2.5\ln y/\varepsilon + 8.5 \qquad \text{for} \qquad y_+ > 30 \tag{6-44}$$

when the dimensionless roughness $\varepsilon_+ = \varepsilon u_*\rho/\mu$ is greater than about 5 to 10; for smaller $\varepsilon_+$, the velocity profile in the turbulent core is unaffected by roughness.

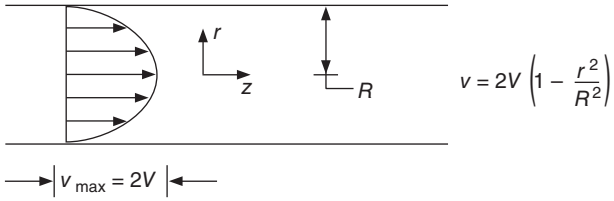

**FIG. 6-10** Parabolic velocity profile for laminar flow in a pipe, with average velocity *V.*

For velocity profiles in the transition region, see Patel and Head [*J. Fluid Mech.* **38:** part 1, 181–201 (1969)] where profiles over the range $1500 < \mathrm{Re} < 10{,}000$ are reported.

**Entrance and Exit Effects** In the entrance region of a pipe, some distance is required for the flow to adjust from upstream conditions to the fully developed velocity profile. This distance depends on the Reynolds number and on the flow conditions upstream. For a uniform velocity profile at the pipe entrance, the computed length in laminar flow required for the centerline velocity to reach 99 percent of its fully developed value is [N. Dombrowski et al., *Can. J. Chem. Engr.* **71:** 472–476 (1993)]

$$L_{\mathrm{ent}}/D = 0.370 \exp(-0.148\ \mathrm{Re}) + 0.0550\ \mathrm{Re} + 0.260 \tag{6-45}$$

In turbulent flow, the entrance length is about

$$L_{\mathrm{ent}}/D = 40 \tag{6-46}$$

The frictional losses in the entrance region are larger than those for the same length of fully developed flow. (See the subsection Frictional Losses in Pipeline Elements later.) At the pipe exit, the velocity profile also undergoes rearrangement, but the exit length is much shorter than the entrance length. At low Re, it is about one pipe radius. At $\mathrm{Re} > 100$, the exit length is negligible.

**Residence Time Distribution** For the parabolic profile for laminar flow in a pipe, neglecting diffusion, the cumulative residence time distribution $F(\theta)$ is given by

$$\begin{aligned} F(\theta) &= 0 \quad \text{for} \quad \theta < \frac{\theta_{\mathrm{avg}}}{2} \\ F(\theta) &= 1 - \frac{1}{4}\left(\frac{\theta_{\mathrm{avg}}}{\theta}\right)^2 \quad \text{for} \quad \theta \ge \frac{\theta_{\mathrm{avg}}}{2} \end{aligned} \tag{6-47}$$

where $F(\theta)$ is the fraction of material that resides in the pipe for less than time $\theta$ and $\theta_{\mathrm{avg}}$ is the average residence time, $\theta = L/V$.

The residence time distribution in long transfer lines may be made narrower (more uniform) with the use of *flow inverters* or *static mixing elements.* These devices exchange fluid between the wall and central regions. Variations on the concept may be used to provide effective mixing of the fluid. See J. C. Godfrey ["Static Mixers," in N. Harnby et al., *Mixing in the Process Industries,* 2d ed., Butterworth Heinemann, Oxford, UK, 1992] and A. W. Etchells and C. F. Meyer ["Mixing in Pipelines," in E. L. Paul et al., *Handbook of Industrial Mixing,* Wiley Interscience, Hoboken, N.J., 2004].

The residence time distribution is narrower for helical coils than for straight pipes, because of the secondary flow which exchanges fluid between the wall and center regions. An equation for laminar flow in helical pipe coils by D. M. Ruthven [*Chem. Eng. Sci.* **26:** 1113–1121 (1971); **33:** 628–629 (1978)] gives

$$F(\theta) = 1 - \left(\frac{1}{4}\right)\left[\frac{\theta_{\mathrm{avg}}}{\theta}\right]^{2.81} \quad \text{for} \quad 0.5 < \frac{\theta_{\mathrm{avg}}}{\theta} < 1.63 \tag{6-48}$$

and agrees with the results of R. N. Trivedi and K. Vasudeva [*Chem. Eng. Sci.* **29:** 2291–2295 (1974)] for $0.6 < \mathrm{De} < 6$ and $0.0036 < D/D_c < 0.097$ where $\mathrm{De} = \mathrm{Re}\sqrt{D/D_c}$ is the *Dean number* and $D_c$ is the diameter of curvature of the coil. Measurements by A. K. Saxena and K. D. P. Nigam [*Chem. Eng. Sci.* **34:** 425–426 (1979)] indicate that such a distribution will hold for $\mathrm{De} > 1$.

In turbulent flow, axial mixing is usually described in terms of turbulent diffusion or dispersion coefficients, from which cumulative residence time distribution functions can be computed. J. T. Davies [*Turbulence Phenomena,* Academic, New York, 1972, p. 93] gives $D_L = 1.01\nu\mathrm{Re}^{0.875}$ for the longitudinal dispersion coefficient. O. Levenspiel [*Chemical Reaction Engineering,* 2d ed., Wiley, New York, 1972, pp. 253–278] discusses the relations among various residence time distribution functions and the relation between dispersion coefficient and residence time distribution.

**Noncircular Channels** Calculation of frictional pressure drop in noncircular channels depends on whether the flow is laminar or turbulent and whether the channel is full or open. For *turbulent flow* in *ducts running full,* the *hydraulic diameter* $D_H$ should be substituted for $D$ in the friction factor and Reynolds number definitions, Eqs. (6-31) and (6-32). The hydraulic diameter is defined as four times the channel cross-sectional area divided by the wetted perimeter. For example, the hydraulic diameter for a circular pipe is $D_H = D$, for an annulus of inner diameter $d$ and outer diameter $D$, $D_H = D - d$, for a rectangular duct of sides $a$, $b$, $D_H = ab/[2(a + b)]$. The **hydraulic radius** $R_H$ is defined as *one-fourth* of the hydraulic diameter.

With the hydraulic diameter substituted for $D$ in $f$ and Re, Eqs. (6-36) through (6-38) are good approximations. Note that $V$ appearing in $f$ and Re is the actual average velocity $V = Q/A$; for noncircular pipes, it is *not* $Q/(\pi D_H^2/4)$. The pressure drop should be calculated from the friction factor for noncircular pipes. Equations relating $Q$ to $\Delta P$ and $D$ for circular pipes *may not be used* for noncircular pipes with $D$ replaced by $D_H$ because $V \ne Q/(\pi D_H^2/4)$.

Turbulent flow in noncircular channels is often accompanied by secondary flows perpendicular to the axial flow direction. These flows may cause the pressure drop to be slightly greater than that computed using the hydraulic diameter method. For data on pressure drop in annuli, see J. A. Brighton and J. B. Jones [*J. Basic Eng.* **86:** 835–842 (1964)]; T. H. Okiishi and G. K. Serovy [*J. Basic Eng.* **89:** 823–836 (1967)]; and C. J. Lawn and C. J. Elliot [*J. Mech. Eng. Sci.* **14:** 195–204 (1972)]. For rectangular ducts of large aspect ratio, R. B. Dean [*J. Fluids Eng.* **100:** 215–233 (1978)] found that the numerator of the exponent in the Blasius equation (6-37) should be increased to 0.0868. O. C. Jones [*J. Fluids Eng.* **98:** 173–181 (1976)] presents a method to improve the estimation of friction factors for rectangular ducts using a modification of the hydraulic diameter–based Reynolds number.

The hydraulic diameter method does not work well for *laminar flow* because the shape affects the flow resistance in a way that cannot be expressed as a function of only the ratio of cross-sectional area to wetted perimeter. For some shapes, the Navier-Stokes equations have been integrated to yield relations between flow rate and pressure drop. These relations may be expressed in terms of *equivalent diameters* $D_E$ defined to make the relations reduce to the second form of the Hagen-Poiseuille equation, Eq. (6-35), that is, $D_E \equiv (128Q\mu L/\pi\,\Delta P)^{1/4}$. *Equivalent diameters are not the same as hydraulic diameters.* Equivalent diameters yield the correct relation between flow rate and pressure drop when substituted into Eq. (6-35), but not Eqs. (6-36) to (6-38) because $V \ne Q/(\pi D_E/4)$.

*Ellipse,* semiaxes $a$ and $b$ [H. Lamb, *Hydrodynamics,* 6th ed., Dover, New York, 1945, p. 587]:

$$D_E = \left(\frac{32a^3b^3}{a^2 + b^2}\right)^{1/4} \tag{6-49}$$

*Rectangle*, width $a$, height $b$ [Owen, *Trans. Am. Soc. Civ. Eng.* **119:** 1157–1175 (1954)]:

$$D_E = \left(\frac{128ab^3}{\pi K}\right)^{1/4} \tag{6-50}$$

| $a/b =$ | 1 | 1.5 | 2 | 3 | 4 | 5 | 10 | ∞ |
|---|---|---|---|---|---|---|---|---|
| $K =$ | 28.45 | 20.43 | 17.49 | 15.19 | 14.24 | 13.73 | 12.81 | 12 |

*Annulus*, inner diameter $D_1$, outer diameter $D_2$ [H. Lamb, *Hydrodynamics,* 6th ed., Dover, New York, 1945, p. 587]:

$$D_E = \left\{\left(D_2^2 - D_1^2\right)\left[D_2^2 + D_1^2 - \frac{D_2^2 - D_1^2}{\ln(D_2/D_1)}\right]\right\}^{1/4} \tag{6-51}$$

For isosceles triangles and regular polygons, see E. M. Sparrow [*AIChE J.* **8:** 599–605 (1962)], L. W. Carlson and T. F. Irvine [*J. Heat Transfer* **83:** 441–444 (1961)], K. C. Cheng [*Proc. Third Int. Heat Transfer Conf.,* New York, **1:** 64–76 (1966)], and F. S. Shit [*Can. J. Chem. Eng.* **45:** 285–294 (1967)].

The critical Reynolds number for *transition from laminar to turbulent flow* in noncircular channels varies with channel shape. In rectangular ducts, $1900 < \mathrm{Re}_c < 2800$ [R. W. Hanks and H.-C. Ruo, *Ind. Eng. Chem. Fundam.* **5:** 558–561 (1966)]. In triangular ducts, $1600 < \mathrm{Re}_c < 1800$ [R. C. Cope and R. W. Hanks, *Ind. Eng. Chem. Fundam.* **11:** 106–117 (1972); P. Bandopadhayay and J. Hinwood, *J. Fluid Mech.* **59:** 775–783 (1973)].

**Nonisothermal Flow** For nonisothermal flow of *liquids,* the friction factor may be increased if the liquid is being cooled or may be decreased if the liquid is being heated, because of the effect of temperature on viscosity near the wall. In shell and tube heat-exchanger design, the recommended practice is to first estimate $f$ using the bulk mean liquid temperature over the tube length. Then, in laminar flow, the result is divided by $(\mu_a/\mu_w)^{0.23}$ in the case of cooling or by $(\mu_a/\mu_w)^{0.38}$ in the case of heating. For turbulent flow, $f$ is divided by $(\mu_a/\mu_w)^{0.11}$ in the case of cooling or by $(\mu_a/\mu_w)^{0.17}$ in case of heating. Here, $\mu_a$ is the viscosity at the average bulk temperature and $\mu_w$ is the viscosity at the average wall temperature [E. N. Seider and G. E. Tate, *Ind. Eng. Chem.* **28:** 1429–1435 (1936)]. In the case of rough commercial pipes, rather than heat-exchanger tubing, it is common for flow to be in the "complete" turbulence regime where $f$ is independent of Re. In such cases, the friction factor should not be corrected for wall temperature. If the liquid density varies with temperature, the average bulk density should

be used to calculate the pressure drop from the friction factor. In addition, a (usually small) correction may be applied for acceleration effects by adding the term $G^2[(1/\rho_2) - (1/\rho_1)]$ from the mechanical energy balance to the frictional pressure drop, where $G$ is the mass velocity. This acceleration results from small compressibility effects associated with temperature-dependent density. E. B. Christiansen and G. E. Gordon [*AIChE J.* **15:** 504–507 (1969)] present equations and charts for frictional loss in laminar nonisothermal flow of newtonian and nonnewtonian liquids heated or cooled with constant wall temperature.

Frictional dissipation of mechanical energy can result in significant heating of fluids, particularly for very viscous liquids in small channels. Under adiabatic conditions, the bulk liquid temperature rise is given by $\Delta T = \Delta P/C_v\rho$ for incompressible flow through a channel of constant cross-sectional area. For flow of polymers, this amounts to about 4°C per 10 MPa (1500 psi) pressure drop, while for hydrocarbon liquids it is about 6°C per 10 MPa. The temperature rise in laminar flow is highly nonuniform, being concentrated near the pipe wall where most of the dissipation occurs. This may result in significant viscosity reduction near the wall, and greatly increased flow or reduced pressure drop, and a flattened velocity profile. Compensation should generally be made for the heat effect when $\Delta P$ exceeds 1.4 MPa (200 psi) for adiabatic walls or 3.5 MPa (500 psi) for isothermal walls [J. E. Gerrard et al., *Ind. Eng. Chem. Fundam.* **4:** 332–339 (1969)].

**Open-Channel Flow** For flow in *open channels,* the data are largely from experiments with water in turbulent flow, in channels of sufficient roughness that there is no Reynolds number effect. The hydraulic radius approach may be used to estimate a friction factor with which to compute friction losses. Under conditions of *uniform flow* where liquid depth and cross-sectional area do not vary significantly with position in the flow direction, there is a balance between gravitational forces and wall stress, or equivalently between frictional losses and potential energy change. The mechanical energy balance in terms of the friction factor and hydraulic diameter or hydraulic radius becomes

$$l_v = \frac{2fV^2L}{D_H} = \frac{fV^2L}{2R_H} = g(Z_1 - Z_2) \tag{6-52}$$

The hydraulic radius is the cross-sectional area divided by the wetted perimeter, where the wetted perimeter *does not include the free surface.* Letting $S = \sin\theta$ = channel slope (elevation loss per unit length of channel, $\theta$ = angle between channel and horizontal), Eq. (6-52) reduces to

$$V = \sqrt{\frac{2gSR_H}{f}} \tag{6-53}$$

The most often used friction correlation for open-channel flows is due to R. Manning [*Trans. Inst. Civ. Engrs. Ireland* **20:** 161 (1891)] and is equivalent to

$$f = \frac{29n^2}{R_H^{1/3}} \tag{6-54}$$

where $n$ is the channel roughness, with dimensions of (length)$^{1/6}$. Table 6-3 gives roughness values for several channel types.

**TABLE 6-3 Average Values of *n* for Manning Formula, Eq. (6-54)**

| Surface | $n$, m$^{1/6}$ | $n$, ft$^{1/6}$ |
|---|---|---|
| Cast-iron pipe, fair condition | 0.014 | 0.011 |
| Riveted steel pipe | 0.017 | 0.014 |
| Vitrified sewer pipe | 0.013 | 0.011 |
| Concrete pipe | 0.015 | 0.012 |
| Wood-stave pipe | 0.012 | 0.010 |
| Planed-plank flume | 0.012 | 0.010 |
| Semicircular metal flumes, smooth | 0.013 | 0.011 |
| Semicircular metal flumes, corrugated | 0.028 | 0.023 |
| Canals and ditches | | |
| Earth, straight and uniform | 0.023 | 0.019 |
| Winding sluggish canals | 0.025 | 0.021 |
| Dredged earth channels | 0.028 | 0.023 |
| Natural-stream channels | | |
| Clean, straight bank, full stage | 0.030 | 0.025 |
| Winding, some pools and shoals | 0.040 | 0.033 |
| Same, but with stony sections | 0.055 | 0.045 |
| Sluggish reaches, very deep pools, rather weedy | 0.070 | 0.057 |

SOURCE: Brater and King, *Handbook of Hydraulics,* 6th ed., McGraw-Hill, New York, 1976, p. 7-22. For detailed information, see Chow, *Open-Channel Hydraulics,* McGraw-Hill, New York, 1959, pp. 110–123.

For gradual changes in channel cross section and liquid depth, and for slopes less than 10°, the momentum equation for a rectangular channel of width $b$ and liquid depth $h$ may be written as a differential equation in the flow direction $x$.

$$\frac{dh}{dx}(1 - \mathrm{Fr}) - \mathrm{Fr}\left(\frac{h}{b}\right)\frac{db}{dx} = S - \frac{fV^2(b+2h)}{2gbh} \tag{6-55}$$

For a given fixed flow rate $Q = Vbh$ and channel width profile $b(x)$, Eq. (6-55) may be integrated to determine the liquid depth profile $h(x)$. The dimensionless Froude number is $\mathrm{Fr} = V^2/gh$. When Fr = 1, the flow is *critical*; when Fr < 1, the flow is *subcritical*; and when Fr > 1, the flow is *supercritical.* Surface disturbances move at a wave velocity $c = \sqrt{gh}$; they cannot propagate upstream in supercritical flows. The *specific energy* $E_{sp}$ is nearly constant.

$$E_{sp} = h + \frac{V^2}{2g} \tag{6-56}$$

This equation is cubic in liquid depth. Below a minimum value of $E_{sp}$ there are no real positive roots; above the minimum value there are two positive real roots. At this minimum value of $E_{sp}$ the flow is critical; that is, Fr = 1, $V = \sqrt{gh}$, and $E_{sp} = (3/2)h$. Near critical flow conditions, wave motion and sudden depth changes called *hydraulic jumps* are likely. V. T. Chow [*Open Channel Hydraulics,* McGraw-Hill, New York, 1959] discusses the numerous surface profile shapes which may exist in nonuniform open-channel flows.

For flow over a *sharp-crested weir* of width $b$ and height $L$, from a liquid depth $H$, the flow rate is given approximately by

$$Q = \frac{2}{3}C_d b\sqrt{2g}(H - L)^{3/2} \tag{6-57}$$

where $C_d \approx 0.6$ is a discharge coefficient. Flow through notched weirs is described under flowmeters in Sec. 10 of this handbook.

**Nonnewtonian Flow** For *isothermal laminar flow* of time-independent nonnewtonian liquids, integration of the Cauchy momentum equation yields the fully developed velocity profile and flow rate–pressure drop relations. For the *Bingham plastic* fluid described by Eq. (6-3), in a pipe of diameter $D$ and a pressure drop per unit length of $\Delta P/L$, the flow rate is given by

$$Q = \frac{\pi D^3\tau_w}{32\mu_\infty}\left[1 - \frac{4\tau_y}{3\tau_w} + \frac{\tau_y^4}{3\tau_w^4}\right] \tag{6-58}$$

where the wall stress is $\tau_w = D\Delta P/(4L)$. The velocity profile consists of a central nondeforming plug of radius $r_P = 2\tau_y/(\Delta P/L)$ and an annular deforming region. The velocity profile in the annular region is given by

$$v_z = \frac{1}{\mu_\infty}\left[\frac{\Delta P}{4L}(R^2 - r^2) - \tau_y(R - r)\right] \quad r_P \le r \le R \tag{6-59}$$

where $r$ is the radial coordinate and $R$ is the pipe radius. The velocity of the central, nondeforming plug is obtained by setting $r = r_P$ in Eq. (6-59). When $Q$ is given and Eq. (6-58) is to be solved for $\tau_w$ and the pressure drop, multiple positive roots for the pressure drop may be found. The root corresponding to $\tau_w < \tau_y$ is physically unrealizable, as it corresponds to $r_P > R$ and the pressure drop is insufficient to overcome the yield stress.

For a *power law fluid,* Eq. (6-4), with constant properties $K$ and $n$, the flow rate is given by

$$Q = \pi\left(\frac{\Delta P}{2KL}\right)^{1/n}\left(\frac{n}{1+3n}\right)R^{(1+3n)/n} \tag{6-60}$$

and the velocity profile by

$$v_z = \left(\frac{\Delta P}{2KL}\right)^{1/n}\left(\frac{n}{1+n}\right)[R^{(1+n)/n} - r^{(1+n)/n}] \tag{6-61}$$

Similar relations for other nonnewtonian fluids may be found in G. W. Govier and K. Aziz [*The Flow of Complex Mixtures in Pipes,* Krieger, Huntington, N.Y., 1977] and in R. B. Bird, R. C. Armstrong, and O. Hassager [*Dynamics of Polymeric Liquids,* vol. 1: *Fluid Mechanics,* Wiley, New York, 1977].

For steady laminar flow of any time-independent viscous fluid, at average velocity $V$ in a pipe of diameter $D$, the Rabinowitsch-Mooney equation gives the shear rate at the pipe wall.

$$\dot{\gamma}_w = \frac{8V}{D}\left(\frac{1+3n'}{4n'}\right) \tag{6-62}$$

where $n'$ is the slope of a plot of $D\Delta P/(4L)$ versus $8V/D$ on logarithmic coordinates,

$$n' = \frac{d \ln [D\Delta P/(4L)]}{d \ln (8V/D)} \tag{6-63}$$

By plotting capillary viscometry data in this way, they can be used directly for pressure drop design calculations, or to construct the rheogram for the fluid. For pressure drop calculation, the flow rate and diameter determine the velocity, from which $8V/D$ is calculated and $D\ \Delta P/(4L)$ read from the plot. For a newtonian fluid, $n' = 1$ and the shear rate at the wall is $\dot{\gamma} = 8V/D$. For a power law fluid, $n' = n$. To construct a rheogram, $n'$ is obtained from the slope of the experimental plot at a given value of $8V/D$. The shear rate at the wall is given by Eq. (6-62), and the corresponding shear stress at the wall is $\tau_w = D\Delta P/(4L)$ read from the plot. By varying the value of $8V/D$, the shear stress versus shear rate plot can be constructed.

The generalized approach of A. B. Metzner and J. C. Reed [*AIChE J.* **1:** 434 (1955)] for time-independent nonnewtonian fluids uses a modified Reynolds number

$$\mathrm{Re}_{\mathrm{MR}} \equiv \frac{D^{n'} V^{2-n'} \rho}{K' 8^{n'-1}} \tag{6-64}$$

where $K'$ satisfies

$$\frac{D\Delta P}{4L} = K' \left( \frac{8V}{D} \right)^{n'} \tag{6-65}$$

With this definition, $f = 16/\mathrm{Re}_{\mathrm{MR}}$ is automatically satisfied at the value of $8V/D$ where $K'$ and $n'$ are evaluated. For newtonian fluids, $K' = \mu$ and $n' = 1$; for power law fluids, $K' = K[(1 + 3n)/(4n)]^n$ and $n' = n$. For Bingham plastics, $K'$ and $n'$ are variable, given as a function of $\tau_w$ (A. B. Metzner, *Ind. Eng. Chem.* **49:** 1429–1432 [1957]).

$$K' = \tau_w^{1-n'} \left[ \frac{\mu_\infty}{1 - 4\tau_y/3\tau_w + (\tau_y/\tau_w)^4/3} \right]^{n'} \tag{6-66}$$

$$n' = \frac{1 - 4\tau_y/(3\tau_w) + (\tau_y/\tau_w)^4/3}{1 - (\tau_y/\tau_w)^4} \tag{6-67}$$

For laminar flow of power law fluids in channels of noncircular cross section, see R. S. Schechter [*AIChE J.* **7:** 445–448 (1961)]; J. A. Wheeler and E. H. Wissler [*AIChE J.* **11:** 207–212 (1965)]; R. B. Bird, R. C. Armstrong, and O. Hassager [*Dynamics of Polymeric Liquids,* vol. 1: *Fluid Mechanics,* Wiley, New York, 1977]; and A. H. P. Skelland [*Nonnewtonian Flow and Heat Transfer,* Wiley, New York, 1967].

Steady, fully developed laminar flows of viscoelastic fluids in straight, constant-diameter pipes show no effects of viscoelasticity. The viscous component of the constitutive equation may be used to develop the flow rate–pressure drop relations, which apply downstream of the entrance region after viscoelastic effects have disappeared. A similar situation exists for time-dependent fluids in pipes of sufficient length.

The *transition to turbulent flow* begins at $\mathrm{Re}_{\mathrm{MR}}$ in the range of 2000 to 2500 [A. B. Metzner and J. C. Reed, *AIChE J.* **1:** 434 (1955)]. For Bingham plastic materials, $K'$ and $n'$ must be evaluated for the $\tau_w$ condition in question in order to determine $\mathrm{Re}_{\mathrm{MR}}$ and establish whether the flow is laminar. An alternative method for Bingham plastics is by R. W. Hanks [*AIChE J.* **9:** 306 (1963); **14:** 691 (1968)]; R. W. Hanks and D. R. Pratt [*Soc. Petrol. Engrs. J.* **7:** 342 (1967)]; and G. W. Govier and K. Aziz [*The Flow of Complex Mixtures in Pipes*, Krieger, Huntington, N.Y., 1977, pp. 213–215]. The transition from laminar to turbulent flow is influenced by *viscoelastic* properties [A. B. Metzner and M. G. Park, *J. Fluid Mech.* **20:** 291 (1964)] with the critical value of $\mathrm{Re}_{\mathrm{MR}}$ increased to beyond 10,000 for some materials. As a rough guide, the lower limit for the Fanning friction factor in laminar flow is ~0.01 for a wide range of rheological behavior.

For *turbulent flow of nonnewtonian fluids,* the design chart of D. W. Dodge and A. B. Metzner [*AIChE J.* **5:** 189 (1959)], Fig. 6-11, is widely used. K. C. Wilson and A. D. Thomas [*Can. J. Chem. Eng.* **63:** 539–546 (1985)] give friction factor equations for turbulent flow of power law fluids and Bingham plastic fluids.

Power law fluids:

$$\frac{1}{\sqrt{f}} = \frac{1}{\sqrt{f_N}} + 8.2\frac{1-n}{1+n} + 1.77 \ln \left( \frac{1+n}{2} \right) \tag{6-68}$$

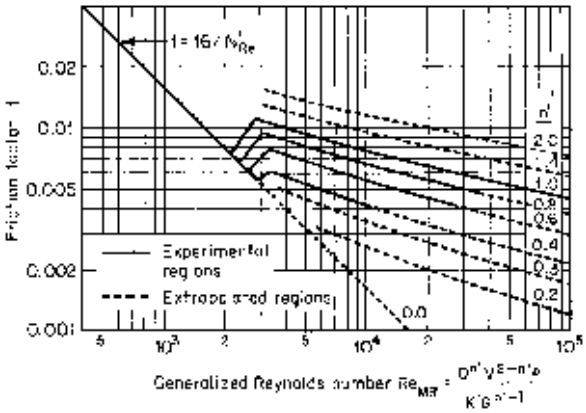

**FIG. 6-11** Fanning friction factor for nonnewtonian flow. The abscissa is defined in Eq. (6-65). [From D. W. Dodge and A. B. Metzner, *Am. Inst. Chem. Eng. J.,* **5:** 189 (1959).]

where $f_N$ is the friction factor for newtonian fluid evaluated at $\mathrm{Re} = DV\rho/\mu_{\mathrm{eff}}$ and where the effective viscosity is

$$\mu_{\mathrm{eff}} = K \left( \frac{3n+1}{4n} \right)^{n-1} \left( \frac{8V}{D} \right)^{n-1} \tag{6-69}$$

Bingham fluids:

$$\frac{1}{\sqrt{f}} = \frac{1}{\sqrt{f_N}} + 1.77 \ln \left( \frac{(1-\xi)^2}{1+\xi} \right) + \xi(10 + 0.884\xi) \tag{6-70}$$

where $f_N$ is evaluated at $\mathrm{Re} = DV\rho/\mu_\infty$ and $\xi = \tau_y/\tau_w$. Iteration is required to use this equation since $\tau_w = f\rho V^2/2$.

**Drag Reduction** In turbulent flow, drag reduction can be achieved by adding soluble high-molecular-weight polymers even in extremely low concentration to newtonian liquids. The reduction in friction is generally believed to be associated with the extensional thickening viscoelastic nature of the solutions effective in the wall region. For a given polymer, there is a minimum molecular weight necessary to initiate drag reduction at a given flow rate, and a critical concentration above which drag reduction will not occur [O. K. Kim, R. C. Little, and R. Y. Ting, *J. Colloid Interface Sci.* **47:** 530–535 (1974)]. Drag reduction is reviewed by J. W. Hoyt [*J. Basic Eng.* **94:** 258–285 (1972)]; R. C. Little et al. [*Ind. Eng. Chem. Fundam.* **14:** 283–296 (1975)]; and P. S. Virk [*AIChE J.* **21:** 625–656 (1975)]. At maximum possible drag reduction in smooth pipes,

$$\frac{1}{\sqrt{f}} = -19 \log \left( \frac{50.73}{\mathrm{Re}\sqrt{f}} \right) \tag{6-71}$$

or approximately,

$$f = \frac{0.58}{\mathrm{Re}^{0.58}} \tag{6-72}$$

for $4000 < \mathrm{Re} < 40{,}000$. The actual drag reduction depends on the polymer system. For further details, see P. S. Virk [*AIChE J.* **21:** 625–656 (1975)]. More recently, K. D. Housiadas and A. N. Beris [*Int. J. Heat Fluid Flow* **42:** 49–67 (2013)] analyzed direct numerical simulation results to develop an expression for the drag reduction, defined as $1 - (f/f_s)$ where $f$ and $f_s$ are the Fanning friction factors for the polymer solution and the pure solvent, respectively, at the same Reynolds number. The expression depends on two parameters, a Weissenberg number and a limiting drag reduction (LDR). The *Weissenberg number* is the ratio of polymer relaxation time to a wall friction time scale. The LDR characterizes the extensional characteristics of the polymer solution rheology, and it depends on the polymer, polymer molecular weight, and polymer concentration. Note that the Reynolds number is defined based on the wall shear viscosity, which can be approximated by the laminar shear viscosity evaluated under the same shear rate conditions [K. D. Housiadas and A. N. Beris, *Int. J. Heat Fluid Flow* **42:** 49–67 (2013) and *Phys. Fluids* **16:** 1581–1586 (2004)].

**Economic Pipe Diameter, Turbulent Flow** The economic optimum pipe diameter may be computed so that the last increment of investment reduces the operating cost enough to produce the required minimum return on investment. For long cross-country pipelines, either alloy pipes of appreciable length and complexity or pipelines with control valves, detailed

analyses of investment, and operating costs should be made. M. Peters and K. Timmerhaus [*Plant Design and Economics for Chemical Engineers,* 4th ed., McGraw-Hill, New York, 1991] provide a detailed method for determining the economic optimum size. For pipelines of the lengths usually encountered in chemical plants and petroleum refineries, simplified selection charts are often adequate. In many cases there is an economic optimum velocity that is nearly independent of diameter, which may be used to estimate the economic diameter from the flow rate. For low-viscosity liquids in Schedule 40 steel pipe, economic optimum velocity is typically in the range of 1.8 to 2.4 m/s (6 to 8 ft/s). For gases with density ranging from 0.2 to 20 kg/m$^3$ (0.012 to 1.2 lbm/ft$^3$), the economic optimum velocity is about 40 to 9 m/s (130 to 30 ft/s). Charts and rough guidelines for economic optimum size do not apply to multiphase flows.

**Economic Pipe Diameter, Laminar Flow** Pipelines for the transport of high-viscosity liquids are seldom designed purely on the basis of economics. More often the size is dictated by operability considerations such as available pressure drop, shear rate, or residence time distribution. M. Peters and K. Timmerhaus [*Plant Design and Economics for Chemical Engineers,* 4th ed., McGraw-Hill, New York, 1991] provide an economic pipe diameter chart for laminar flow. For nonnewtonian fluids, see A. H. P. Skelland [*Nonnewtonian Flow and Heat Transfer,* Wiley, New York, 1967].

**Vacuum Flow** When gas flows under high vacuum conditions or through very small openings, the continuum hypothesis is no longer appropriate if the channel dimension is not very large compared to the mean free path of the gas. When the mean free path is comparable to the channel dimension, flow is dominated by collisions of molecules with the wall, rather than by collisions between molecules. An approximate expression based on G. P. Brown et al. [*J. Appl. Phys.* **17:** 802–813 (1946)] for the mean free path is

$$\lambda = \left(\frac{2\mu}{p}\right)\sqrt{\frac{8RT}{\pi M_w}} \tag{6-73}$$

The Knudsen number Kn is the ratio of the mean free path to the channel dimension. For pipe flow, Kn = $\lambda/D$. *Molecular flow* is characterized by Kn > 1.0; *continuum viscous* (laminar or turbulent) flow is characterized by Kn < 0.01. *Transition* or *slip* flow applies over the range 0.01 < Kn < 1.0.

Vacuum flow is usually described with flow variables different from those used for normal pressures, often leading to confusion. *Pumping speed S* is the actual volumetric flow rate of gas through a flow cross section. *Throughput Q* is the product of pumping speed and absolute pressure. In SI, $Q$ has units of Pa · m$^3$/s.

$$Q = Sp \tag{6-74}$$

The mass flow rate $w$ is related to the throughput by using the ideal gas law.

$$w = \frac{M_w}{RT}Q \tag{6-75}$$

The relation between throughput and pressure drop $\Delta p = p_1 - p_2$ across a flow element is written in terms of the *conductance C. Resistance* is the reciprocal of conductance. Conductance has dimensions of volume per time.

$$Q = C\,\Delta p \tag{6-76}$$

The conductance of a series of flow elements is given by

$$\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} + \cdots \tag{6-77}$$

while for elements in parallel,

$$C = C_1 + C_2 + C_3 + \cdots \tag{6-78}$$

For a vacuum pump of speed $S_p$ withdrawing from a vacuum vessel through a connecting line of conductance $C$, the pumping speed at the vessel is

$$S = \frac{S_p C}{S_p + C} \tag{6-79}$$

**Molecular Flow** Under molecular flow conditions, conductance is independent of pressure. It is proportional to $\sqrt{T/M_w}$, with the proportionality constant a function of geometry. For fully developed pipe flow,

$$C = \frac{\pi D^3}{8L}\sqrt{\frac{RT}{M_w}} \tag{6-80}$$

**TABLE 6-4 Constants for Circular Annuli**

| $D_2/D_1$ | $K$ | $D_2/D_1$ | $K$ |
|---|---|---|---|
| 0 | 1.00 | 0.707 | 1.254 |
| 0.259 | 1.072 | 0.866 | 1.430 |
| 0.500 | 1.154 | 0.966 | 1.675 |

For an orifice of area $A$,

$$C = 0.40A\sqrt{\frac{RT}{M_w}} \tag{6-81}$$

Conductance equations for several other geometries are given by J. L. Ryans and D. L. Roper [*Process Vacuum System Design and Operation,* chap. 2, McGraw-Hill, New York, 1986]. For a circular annulus of outer and inner diameters $D_1$ and $D_2$ and length $L$, the method of A. Guthrie and R. K. Wakerling [*Vacuum Equipment and Techniques,* McGraw-Hill, New York, 1949] may be written

$$C = 0.42K\frac{(D_1 - D_2)^2\,(D_1 + D_2)}{L}\sqrt{\frac{RT}{M_w}} \tag{6-82}$$

where $K$ is a dimensionless constant with values given in Table 6-4.

For a short pipe of circular cross section, the conductance as calculated for an orifice from Eq. (6-81) is multiplied by a correction factor $K$ which may be approximated as [E. H. Kennard, *Kinetic Theory of Gases,* McGraw-Hill, New York, 1938, pp. 306–308]

$$K = \frac{1}{1 + (L/D)} \qquad \text{for} \qquad 0 \le L/D \le 0.75 \tag{6-83}$$

$$K = \frac{1 + 0.8(L/D)}{1 + 1.90(L/D) + 0.6(L/D)^2} \qquad \text{for} \qquad L/D > 0.75 \tag{6-84}$$

For $L/D > 100$, the error in neglecting the end correction by using the fully developed pipe flow equation, Eq. (6-80), is less than 2 percent. For rectangular channels, see C. E. Normand [*Ind. Eng. Chem.* **40:** 783–787 (1948)].

H. S. Yu and E. M. Sparrow [*J. Basic Eng.* **70:** 405–410 (1970)] give a chart for slot seals with or without a sheet located in or passing through the seal, giving the mass flow rate as a function of the ratio of seal plate thickness to gap opening.

**Slip Flow** In the transition region between molecular flow and continuum viscous flow, the conductance for fully developed pipe flow is most easily obtained by the method of G. P. Brown et al. [*J. Appl. Phys.* **17:** 802–813 (1946)] which uses the parameter

$$X = \sqrt{\frac{8}{\pi}}\left(\frac{\lambda}{D}\right) = \left(\frac{2\mu}{p_m D}\right)\sqrt{\frac{RT}{M}} \tag{6-85}$$

where $p_m$ is the arithmetic mean absolute pressure. A correction factor $F$, read from Fig. 6-12 as a function of $X$, is applied to the conductance for viscous flow.

$$C = F\frac{\pi D^4 p_m}{128\,\mu L} \tag{6-86}$$

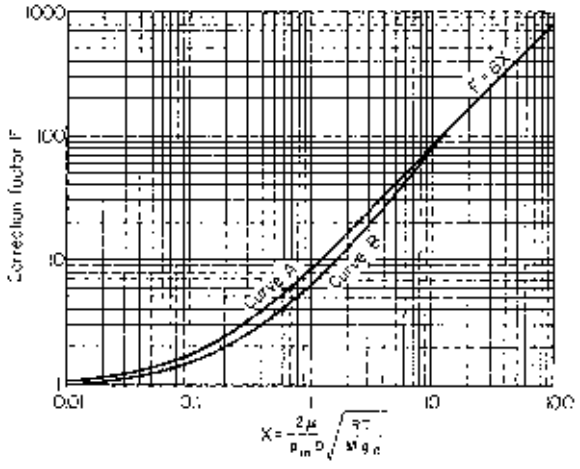

**FIG. 6-12** Correction factor for Poiseuille's equation at low pressures. Curve *A:* experimental curve for glass capillaries and smooth metal tubes. [From G. P. Brown, et al., *J. Appl. Phys.*, **17,** 802 (1946).] Curve *B:* experimental curve for iron pipe. [From Riggle, *courtesy of E. I. du Pont de Nemours & Co.*]

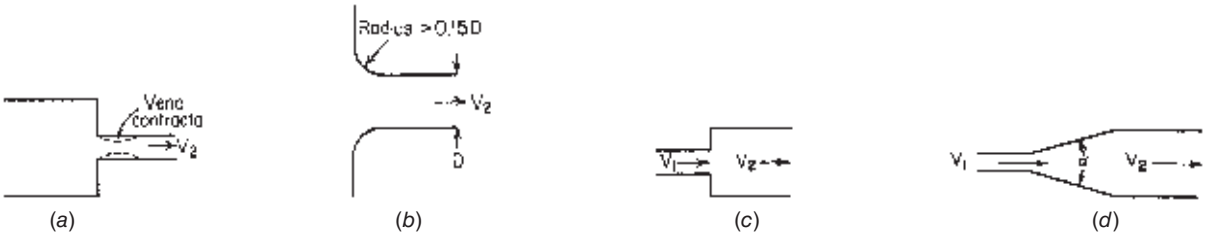

**FIG. 6-13** Contractions and enlargements: (*a*) sudden contraction, (*b*) rounded contraction, (*c*) sudden enlargement, and (*d*) uniformly diverging duct.

For slip flow through *square channels,* see M. W. Milligan and H. J. Wilkerson [*J. Eng. Ind.* **95:** 370–372 (1973)]. For slip flow through *annuli,* see W. J. Maegley and A. S. Berman [*Phys. Fluids* **15:** 780–785 (1972)].

The *pump-down time* θ for evacuating a vessel in the absence of air in-leakage is given approximately by

$$\theta = \left(\frac{V_t}{S_0}\right) \ln\left(\frac{p_1 - p_0}{p_2 - p_0}\right) \tag{6-87}$$

where $V_t$ = volume of vessel plus volume of piping between vessel and pump; $S_0$ = system speed as given by Eq. (6-79), assumed independent of pressure; $p_1$ = initial vessel pressure; $p_2$ = final vessel pressure; and $p_0$ = lowest pump intake pressure attainable with the pump in question. See S. Dushman and J. M. Lafferty [*Scientific Foundations of Vacuum Technique,* 2d ed., Wiley, New York, 1962].

The rate at which inert materials must be removed by a pumping system after the pump-down stage depends on the in-leakage of air at the various fittings, connections, etc. Air leakage is often correlated with system volume and pressure, but this approach is uncertain because the number and size of leaks may not correlate with system volume, and leakage is sensitive to maintenance quality. J. L. Ryans and D. L. Roper [*Process Vacuum System Design and Operation,* chap. 2, McGraw-Hill, New York, 1986] present a thorough discussion of air leakage.

## FRICTIONAL LOSSES IN PIPELINE ELEMENTS

The viscous loss term in the mechanical energy balance for most cases is obtained experimentally. For many common fittings found in piping systems, such as expansions, contractions, elbows, and valves, data are available to estimate the losses. Substitution into the energy balance allows calculation of pressure drop. A common error is to assume that pressure drop and frictional losses are equivalent. Equation (6-19) shows that in addition to frictional losses, other factors such as shaft work and velocity or elevation change influence pressure drop.

Losses $l_v$ for incompressible flow in sections of straight pipe of constant diameter may be calculated as previously described, using the Fanning friction factor:

$$l_v = \frac{\Delta P}{\rho} = \frac{2fV^2L}{D} \tag{6-88}$$

where $\Delta P$ = drop in equivalent pressure, $P = p + \rho gZ$, with $p$ = pressure, ρ = fluid density, $g$ = acceleration of gravity, and $Z$ = elevation. Losses in the fittings of a piping network are frequently termed *minor losses* or *miscellaneous losses.* These descriptions are misleading because in process piping fitting losses may be greater than the losses in straight piping sections.

**Equivalent Length and Velocity Head Methods** Two methods are in common use for estimating fitting loss. The *equivalent length* method reports the losses in a piping element as the length of straight pipe which would have the same loss. For turbulent flows, the equivalent length is usually reported as a number of diameters of pipe of the same size as the fitting connection; $L_e/D$ is given as a fixed quantity, independent of $D$. This approach tends to be most accurate for a single fitting size and loses accuracy with deviation from this size. For laminar flows, $L_e/D$ correlations normally have size dependence through a Reynolds number term.

The other method is the *velocity head* method. The term $V^2/2g$ has dimensions of length and is commonly called a *velocity head* but this name is also used for $\rho V^2/2$. In the velocity head method, the losses are reported as a number of velocity heads $K$. Then the engineering Bernoulli equation for an incompressible fluid can be written as

$$p_1 - p_2 = \alpha_2 \frac{\rho V_2^2}{2} - \alpha_1 \frac{\rho V_1^2}{2} + \rho g(Z_2 - Z_1) + K\frac{\rho V^2}{2} \tag{6-89}$$

where $V$ is the reference velocity upon which the velocity head loss coefficient $K$ is based. For a section of straight pipe, $K = 4fL/D$.

**Contraction and Entrance Losses** For a *sudden contraction* at a sharp-edged entrance to a pipe or sudden reduction in cross-sectional area of a channel, as shown in Fig. 6-13*a,* the loss coefficient based on the downstream velocity $V_2$ is given for *turbulent flow* in Crane Co. [Tech. Paper 410 1980] approximately by

$$K = 0.5\left(1 - \frac{A_2}{A_1}\right) \tag{6-90}$$

***Example 6-5 Entrance Loss*** Water, ρ = 1000 kg/m$^3$, flows from a large vessel through a sharp-edged entrance into a pipe at a velocity in the pipe of 2 m/s. The flow is turbulent. Estimate the pressure drop from the vessel into the pipe.

With $A_2/A_1 \sim 0$, the viscous loss coefficient is $K = 0.5$ from Eq. (6-90). The mechanical energy balance, Eq. (6-19) with $V_1 = 0$ and $Z_2 - Z_1 = 0$ and assuming uniform flow ($\alpha_2 = 1$), becomes

$$p_1 - p_2 = \frac{\rho V_2^2}{2} + 0.5\frac{\rho V_2^2}{2} = 2000 + 1000 = 3000 \text{ Pa}$$

Note that the total pressure drop consists of 0.5 velocity head of frictional loss, and 1 velocity head of acceleration. The frictional contribution is a permanent loss of mechanical energy. The acceleration contribution is reversible; if the fluid were subsequently decelerated in a frictionless diffuser, a pressure rise would occur.

For a *trumpet-shaped* rounded entrance, with a radius of rounding greater than about 15 percent of the pipe diameter (Fig. 6-13*b*), the turbulent flow loss coefficient $K$ is only about 0.1 [J. F. Vennard and R. L. Street, *Elementary Fluid Mechanics,* 5th ed., Wiley, New York, 1975, pp. 420–421]. Rounding of the inlet prevents formation of the *vena contracta,* reducing the resistance to flow.

For *laminar flow* the losses in sudden contraction may be estimated for area ratios $A_2/A_1 < 0.2$ by an equivalent additional pipe length $L_e$ given by

$$L_e/D = 0.3 + 0.04\,\text{Re} \tag{6-91}$$

where $D$ is the diameter of the smaller pipe and Re is the Reynolds number in the smaller pipe. For laminar flow in the entrance to rectangular ducts, see R. K. Shah [*J. Fluids Eng.* **100:** 177–179 (1978)]. For creeping flow, Re < 1, of power law fluids, the entrance loss is approximately $L_e/D = 0.3/n$ [D. V. Boger et al., *J. Nonnewtonian Fluid Mech.* **4:** 239–248 (1978)]. For viscoelastic fluid flow in circular channels with sudden contraction, a toroidal vortex forms upstream of the contraction plane. Such flows are reviewed by D. V. Boger [*Ann. Review Fluid Mech.* **19:** 157–182 (1987)].

For creeping flow through *conical converging channels,* the viscous pressure drop $\Delta p = \rho l_v$ may be computed by integration of the differential form of the Hagen-Poiseuille equation, Eq. (6-35), provided the angle of convergence is small. The result for a power law fluid is

$$\Delta p = 4K\left(\frac{3n+1}{4n}\right)^n \left(\frac{8V_2}{D_2}\right)^n \left\{\frac{1}{6n\tan(\alpha/2)}\left[1 - \left(\frac{D_2}{D_1}\right)^{3n}\right]\right\} \tag{6-92}$$

where $D_1$ = inlet diameter
$D_2$ = exit diameter
$V_2$ = velocity at the exit
α = total included angle

Equation (6-92) agrees with experimental data [Z. Kemblowski and T. Kiljanski, *Chem. Eng. J.* (*Lausanne*), **9:** 141–151 (1975)] for α < 11°. For newtonian liquids, Eq. (6-95) simplifies to

$$\Delta p = \mu\left(\frac{32V_2}{D_2}\right)\left\{\frac{1}{6\tan(\alpha/2)}\left[1 - \left(\frac{D_2}{D_1}\right)^3\right]\right\} \tag{6-93}$$

For creeping flow through noncircular converging channels, the differential form of the Hagen-Poiseuille equation with equivalent diameter given by Eqs. (6-49) to (6-51) may be used, provided the convergence is gradual.

**Expansion and Exit Losses** For ducts of any cross section, the frictional loss for a *sudden enlargement* (Fig. 6-13*c*) with turbulent flow is given by the Borda-Carnot equation:

$$l_v = \frac{V_1^2 - V_2^2}{2} = \frac{V_1^2}{2}\left(1 - \frac{A_1}{A_2}\right)^2 \tag{6-94}$$

where $V_1$ = velocity in smaller duct
$V_2$ = velocity in larger duct
$A_1$ = cross-sectional area of smaller duct
$A_2$ = cross-sectional area of larger duct

Equation (6-94) is valid for incompressible flow. For compressible flows, see R. P. Benedict et al. [*J. Eng. Power* **98:** 327–334 (1976)]. For an infinite expansion, $A_1/A_2 = 0$, Eq. (6-97) shows that the *exit loss* from a pipe is 1 velocity head. This exit loss is due to the dissipation of the discharged jet; there is no pressure drop at the exit.

For creeping newtonian flow (Re < 1), the frictional loss due to a sudden enlargement should be obtained from the same equation for a sudden contraction, Eq. (6-91). Note, however, that D. V. Boger et al. [*J. Nonnewtonian Fluid Mech.* **4:** 239–248 (1978)] give an exit friction equivalent length of 0.12 diameter, increasing for power law fluids as the exponent decreases. For laminar flows at higher Reynolds numbers, the pressure drop is twice that given by Eq. (6-91). This results from the velocity profile factor $\alpha$ in the mechanical energy balance being 2.0 for the parabolic laminar velocity profile.

If the transition from a small to a large duct of any cross-sectional shape is accomplished by a *uniformly diverging duct* (see Fig. 6-13*d*) with a straight axis, the total frictional pressure drop can be computed by integrating the differential form of Eq. (6-88), $dl_v/dx = 2fV^2/D$ over the length of the expansion, provided the total angle $\alpha$ between the diverging walls is less than 7°. For angles between 7° and 45°, the loss coefficient may be estimated as 2.6 sin ($\alpha$/2) times the loss coefficient for a sudden expansion; see W. B. Hooper [*Chem. Eng.* Nov. 7, 1988]. A. H. Gibson [*Hydraulics and Its Applications,* 5th ed., Constable, London, 1952, p. 93] recommends multiplying the sudden enlargement loss by 0.13 for $5° < \alpha < 7.5°$ and by $0.0110\alpha^{1.22}$ for $7.5° < \alpha < 35°$. For angles greater than 35° to 45°, the losses are normally considered equal to those for a sudden expansion, although in some cases the losses may be greater. Expanding flow through standard pipe reducers should be treated as sudden expansions.

*Trumpet-shaped enlargements* for *turbulent flow* designed for constant decrease in velocity head per unit length were found by A. H. Gibson [*Hydraulics and Its Applications,* 5th ed., Constable, London, 1952, p. 95] to give 20 to 60 percent less frictional loss than straight taper pipes of the same length.

When *viscoelastic* liquids are extruded through a die at a low Reynolds number, the extrudate may expand to a diameter several times greater than the die diameter, whereas for a newtonian fluid the diameter expands only 10 percent. This phenomenon, called *die swell,* is most pronounced with short dies [W. W. Graessley et al., *Trans. Soc. Rheol.* **14:** 519–544 (1970)]. For velocity distribution measurements near the die exit, see D. D. Goulden and W. C. MacSporran [*J. Nonnewtonian Fluid Mech.* **1:** 183–198 (1976)] and B. A. Whipple and C. T. Hill [*AIChE J.* **24:** 664–671 (1978)]. At high flow rates, the extrudate becomes distorted, suffering *melt fracture,* a phenomenon reviewed by M. M. Denn [*Ann. Review Fluid Mech.* **22:** 13–34 (1990)]. A. V. Ramamurthy [*J. Rheol.* **30:** 337–357 (1986)] found a dependence of apparent stick-slip behavior in melt fracture to be dependent on the material of construction of the die.

**Fittings and Valves** For *turbulent flow,* the frictional loss for fittings and valves can be expressed by the equivalent length or velocity head methods. As fitting size is varied, $K$ values are relatively more constant than $L_e/D$ values, but since fittings generally do not achieve geometric similarity between sizes, $K$ values tend to decrease with increasing fitting size. Table 6-5 gives $K$ values for many types of fittings and valves.

Manufacturers of valves, especially control valves, express valve capacity in terms of a flow coefficient $C_v$, which gives the flow rate through the valve in gallons per minute of water at 60°F under a pressure drop of 1 lbf/in$^2$. It is related to $K$ by

$$C_v = \frac{C_1 d^2}{\sqrt{K}} \tag{6-95}$$

where $C_1$ is a dimensional constant equal to 29.9 and $d$ is the diameter of the valve connections in inches.

**TABLE 6-5 Additional Frictional Loss for Turbulent Flow Through Fittings and Valves[a]**

| Type of fitting or valve | Additional friction loss, equivalent no. of velocity heads, $K$ |
|---|---|
| 45° ell, standard[b,c,d,e,f] | 0.35 |
| 45° ell, long radius[c] | 0.2 |
| 90° ell, standard[b,c,e,f,g,h] | 0.75 |

For *laminar* and *turbulent flow,* the "2K" method of W. B. Hooper [*Chem. Eng.* **88**(17), 96–100 (August 1981)] yields approximate fitting losses accounting for Re and fitting size of

$$K = \frac{K_1}{\mathrm{Re}} + K_\infty\left(1 + \frac{1}{d}\right) \tag{6-96}$$

where $d$ is the fitting size in inches and $K_1$ and $K_\infty$ are shown in length and homogeneous equilibrium flow at 100.

Methods to calculate losses in *tee and wye junctions* for dividing and combining flow are given by D. S. Miller [*Internal Flow Systems,* 2d ed., chap. 13, British Hydrodynamics Research Association, Cranfield, UK, 1990], including effects of Reynolds number, angle between legs, area ratio, and radius. Junctions with more than three legs are also discussed. The sources of data for the loss coefficient charts are F. W. Blaisdell and P. W. Manson [*U.S. Dept. Agric. Res. Serv. Tech. Bull.* 1283 (August 1963)] for combining flow and A. Gardel [*Bull. Tech. Suisses Romande* **85**(9): 123–130 (1957); **85**(10): 143–148 (1957)] together with additional unpublished data for dividing flow.

D. S. Miller [*Internal Flow Systems,* 2d ed., chap. 13, British Hydrodynamics Research Association, Cranfield, UK, 1990] gives the most complete information on losses in *bends and curved pipes.* For turbulent flow in circular cross-section bends of constant area, as shown in Fig. 6-14*a,* a more accurate estimate of the loss coefficient $K$ than that given in Tables 6-5 and 6-6 is

$$K = K^* C_{\mathrm{Re}} C_o C_f \tag{6-97}$$

where $K^*$, given in Fig. 6-14*b*, is the loss coefficient for a smooth-walled bend at a Reynolds number of $10^6$. The Reynolds number correction factor $C_{\mathrm{Re}}$ is given in Fig. 6-14*c*. For $0.7 < r/D < 1$ or for $K^* < 0.4$, use the $C_{\mathrm{Re}}$ value for $r/D = 1$. Otherwise, if $r/D < 1$, obtain $C_{\mathrm{Re}}$ from

$$C_{\mathrm{Re}} = \frac{K^*}{K^* + 0.2(1 - C_{\mathrm{Re},\,r/D=1})} \tag{6-98}$$

The correction $C_o$ (Fig. 6-14*d*) accounts for the extra losses due to developing flow in the outlet tangent of the pipe, of length $L_o$. The total loss for the bend plus outlet pipe includes the bend loss $K$ plus the straight pipe frictional loss in the outlet pipe $4fL_o/D$. Note that $C_o = 1$ for $L_o/D$ greater than the termination of the curves on Fig. 6-14*d*, which indicate the distance at which fully developed flow in the outlet pipe is reached. Finally, the roughness correction is

$$C_f = \frac{f_{\mathrm{rough}}}{f_{\mathrm{smooth}}} \tag{6-99}$$

where $f_{\mathrm{rough}}$ is the friction factor for a pipe of diameter $D$ with the roughness of the bend, at the bend inlet Reynolds number. Similarly, $f_{\mathrm{smooth}}$ is the friction factor for smooth pipe. For $\mathrm{Re} > 10^6$ and $r/D \geq 1$, use the value of $C_f$ for $\mathrm{Re} = 10^6$.

***Example 6-6 Losses with Fittings and Valves*** It is desired to calculate the liquid level in the vessel shown in Fig. 6-15 required to produce a discharge velocity of 2 m/s. The fluid is water at 20°C with $\rho = 1000$ kg/m$^3$ and $\mu = 0.001$ Pa · s, and the butterfly valve is at $\theta = 10°$. The pipe is 2-in Schedule 40, with an inner diameter of 0.0525 m. The pipe roughness is 0.046 mm. Assuming the flow is turbulent and taking the velocity profile factor $\alpha = 1$, the engineering Bernoulli equation, Eq. (6-19), written between surfaces 1 and 2, where the pressures are both atmospheric and the fluid velocities are zero and $V = 2$ m/s, respectively, and there is no shaft work, simplifies to

$$gZ = \frac{V^2}{2} + l_v$$

Contributing to $l_v$ are losses for the entrance to the pipe, the three sections of straight pipe, the butterfly valve, and the 90° bend. Note that no exit loss is used because the discharged jet is outside the control volume. Instead, the $V^2/2$ term accounts for the kinetic energy of the discharging stream. The Reynolds number in the pipe is

$$\mathrm{Re} = \frac{DV\rho}{\mu} = \frac{0.0525 \times 2 \times 1000}{0.001} = 1.05 \times 10^5$$

From Fig. 6-9 or Eq. (6-37), at $\varepsilon/D = 0.046 \times 10^{-3}/0.0525 = 0.00088$, the friction factor is about 0.0054. The straight pipe losses are then

$$l_{v(\mathrm{sp})} = \left(\frac{4fL}{D}\right)\frac{V^2}{2} = \left(\frac{4 \times 0.0054 \times (1+1+1)}{0.0525}\right)\frac{V^2}{2} = 1.23\frac{V^2}{2}$$

The losses from Table 6-5 in terms of velocity heads $K$ are $K = 0.5$ for the sudden contraction and $K = 0.52$ for the butterfly valve. For the 90° standard radius ($r/D = 1$), the table gives $K = 0.75$. The value calculated using Table 6-6 is 0.38. The method of Eq. (6-97), using Fig. 6-14, gives

$$K = K^* C_{\mathrm{Re}} C_o C_f = 0.24 \times 1.24 \times 1.0 \times \left(\frac{0.0054}{0.0044}\right) = 0.37$$

This value is close to the value from Table 6-6, and more accurate than the value in Table 6-5. The value $f_{\mathrm{smooth}} = 0.0044$ is obtainable from Eq. (6-36) or Fig. 6-9.

The total losses are then

$$l_v = (1.23 + 0.5 + 0.52 + 0.37)\frac{V^2}{2} = 2.62\frac{V^2}{2}$$

and the liquid level $Z$ is

$$Z = \frac{1}{g}\left(\frac{V^2}{2} + 2.62\frac{V^2}{2}\right) = 3.62\frac{V^2}{2g} = \frac{3.62 \times 2^2}{2 \times 9.807} = 0.74 \text{ m}$$

**Curved Pipes and Coils** For flow through curved pipe or coil, a secondary circulation perpendicular to the main flow called the *Dean effect* occurs. This increases the friction relative to straight pipe flow and stabilizes laminar flow, delaying the transition Reynolds number to about

$$\mathrm{Re}_{\mathrm{crit}} = 2100\left(1 + 12\sqrt{\frac{D}{D_c}}\right) \tag{6-100}$$

where $D_c$ is the coil diameter. Equation (6-100) is valid for $10 < D_c/D < 250$. The *Dean number* is defined as

$$\mathrm{De} = \frac{\mathrm{Re}}{(D_c/D)^{1/2}} \tag{6-101}$$

**TABLE 6-6 2-K Method Friction Loss Parameters**

| Fitting or valve | | | | $K_1$ | $K_\infty$ |
|---|---|---|---|---|---|
| Elbows | 45° | Standard ($R/D = 1$) screwed, flanged, or welded | | 500 | 0.20 |
| | | Long radius ($R/D = 1.5$) | | 500 | 0.15 |

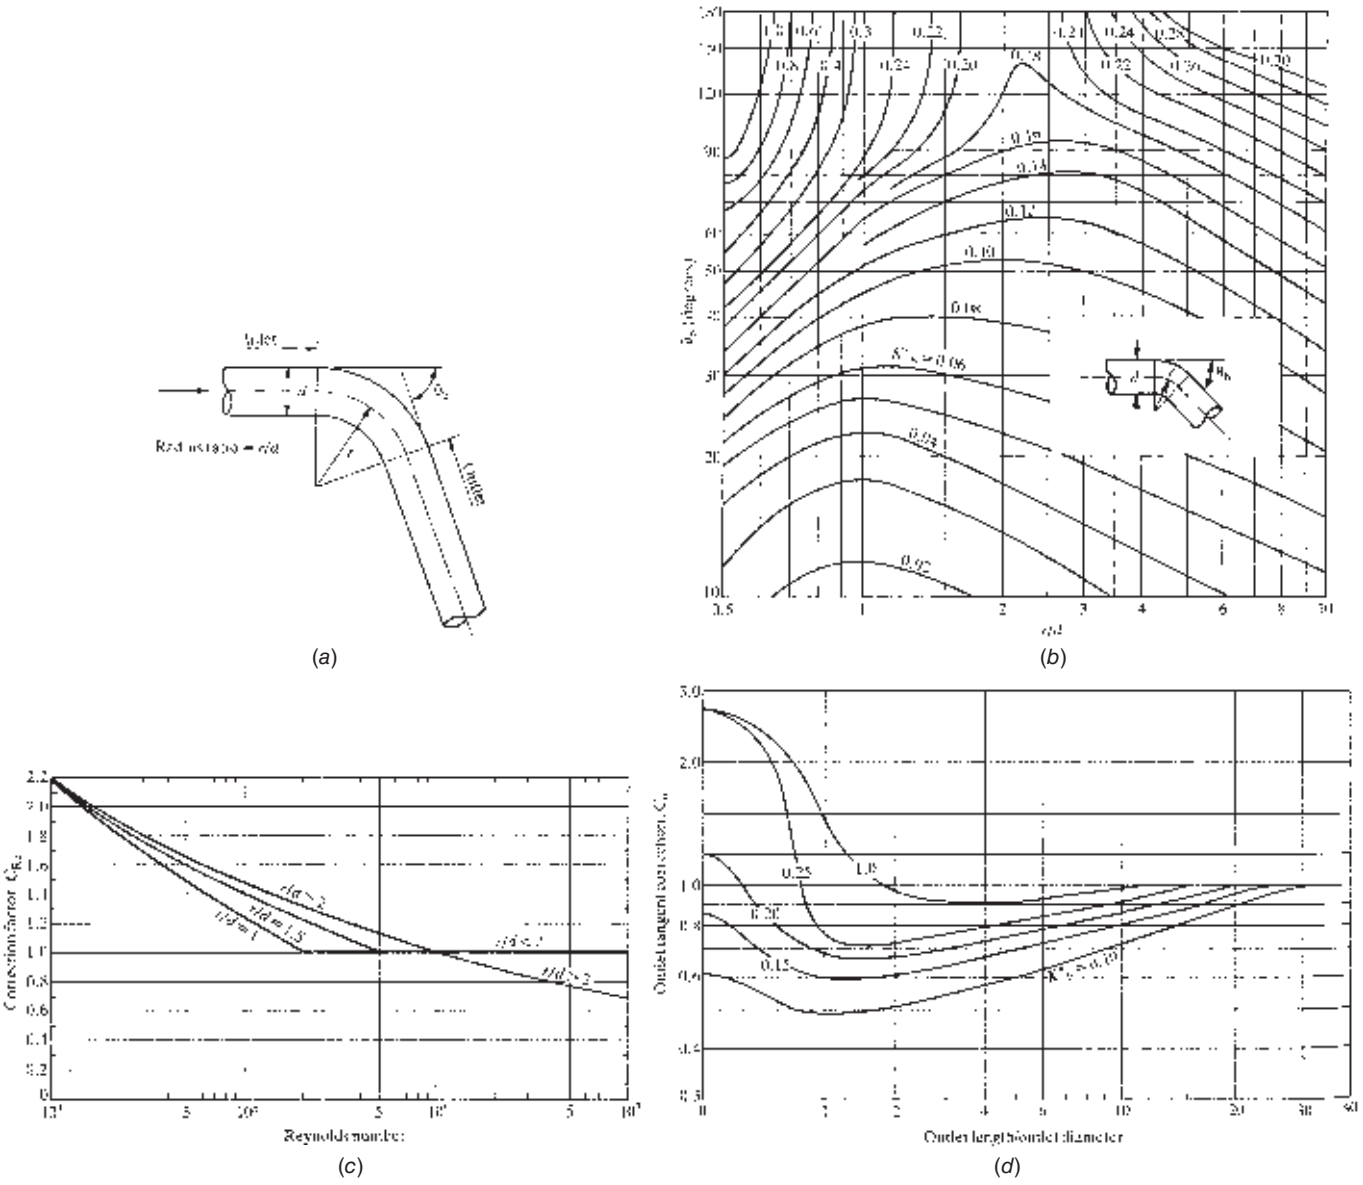

**FIG. 6-14** Loss coefficients for flow in bends and curved pipes: (*a*) flow geometry, (*b*) loss coefficient for a smooth-walled bend at Re = $10^6$, (*c*) Re correction factor, (*d*) outlet pipe correction factor. [From D. S. Miller, *Internal Flow Systems*, 2d ed., BHRA, Cranfield, U.K., 1990.]

In laminar flow, the friction factor for curved pipe $f_c$ may be expressed in terms of the straight pipe friction factor $f = 16/\mathrm{Re}$ as [J. Hart et al., *Chem. Eng. Sci.* **43:** 775–783 (1988)]

$$f_c/f = 1 + 0.090\left(\frac{\mathrm{De}^{1.5}}{70 + \mathrm{De}}\right) \tag{6-102}$$

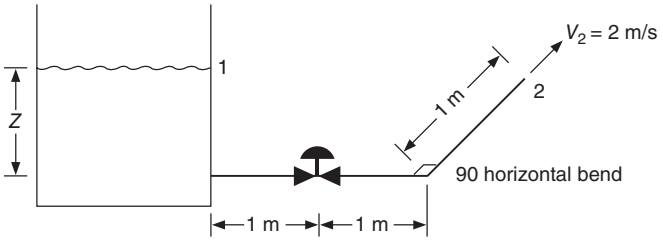

**FIG. 6-15** Tank discharge example.

For turbulent flow, equations by H. Ito [*J. Basic Eng.* **81:** 123 (1959)] and P. S. Srinivasan et al. [*Chem. Eng.* (*London*) no. 218, CE113–CE119 (May 1968)] may be used, with probable accuracy of ±15 percent. Their equations are similar to

$$f_c = \frac{0.079}{\mathrm{Re}^{0.25}} + \frac{0.0073}{\sqrt{(D_c/D)}} \tag{6-103}$$

The pressure drop for flow in *spirals* is discussed by P. S. Srinivasan et al. [*Chem. Eng.* (*London*) no. 218, CE113–CE119 (May 1968)] and S. Ali and C. V. Seshadri [*Ind. Eng. Chem. Process Des. Dev.* **10:** 328–332 (1971)]. For friction loss in laminar flow through *semicircular ducts,* see J. H. Masliyah and K. Nandakumar [*AIChE J.* **25:** 478–487 (1979)]; for curved channels of *square cross section,* see K. C. Cheng et al. [*J. Fluids Eng.* **98:** 41–48 (1976)].

For *nonnewtonian* (*power law*) *fluids* in coiled tubes, R. A. Mashelkar and G. V. Devarajan [*Trans. Inst. Chem. Eng.* (*London*), **54:** 108–114 (1976)] propose the correlation

$$f_c = (9.07 - 9.44n + 4.37n^2)(D/D_c)^{0.5}(\mathrm{De}')^{-0.768 + 0.122n} \tag{6-104}$$

where De′ is a modified Dean number given by

$$\mathrm{De}' = \frac{1}{8}\left(\frac{6n+2}{n}\right)^n \mathrm{Re}_{\mathrm{MR}}\sqrt{\frac{D}{D_c}} \tag{6-105}$$

and $\mathrm{Re}_{\mathrm{MR}}$ is the Metzner-Reed Reynolds number, Eq. (6-64). This correlation was tested for the range De′ = 70 to 400, $D/D_c = 0.01$ to 0.135, and $n = 0.35$ to 1. See also D. R. Oliver and S. M. Asghar [*Trans. Inst. Chem. Eng.* (*London*), **53:** 181–186 (1975)].

**Screens** The pressure drop for incompressible flow across a screen of fractional free area α may be computed from

$$\Delta p = K\frac{\rho V^2}{2} \tag{6-106}$$

where ρ = fluid density
$V$ = superficial velocity based on gross area of the screen
$K$ = velocity head loss

$$K = \left(\frac{1}{C^2}\right)\left(\frac{1-\alpha^2}{\alpha^2}\right) \tag{6-107}$$

The discharge coefficient for the screen $C$ with aperture $D_s$ is given as a function of screen Reynolds number $\mathrm{Re} = D_s(V/\alpha)\rho/\mu$ in Fig. 6-16 for *plain square-mesh screens,* $\alpha = 0.14$ to 0.79. This curve fits most of the data within ±20 percent. In the laminar flow region, Re < 20, the discharge coefficient can be computed from

$$C = 0.1\sqrt{\mathrm{Re}} \tag{6-108}$$

Coefficients greater than 1.0 in Fig. 6-16 probably indicate partial pressure recovery downstream of the minimum aperture, due to rounding of the wires.

P. Grootenhuis [*Proc. Inst. Mech. Eng.* (*London*), **A168:** 837–846 (1954)] presents data indicating that for a series of screens, the total pressure drop equals the number of screens times the pressure drop for one screen, and is not affected by the spacing between screens or their orientation with respect to one another, and presents a correlation for frictional losses across plain square-mesh screens and sintered gauzes. Armour and Cannon [*AIChE J.* **14:** 415–420 (1968)] give a correlation based on a packed-bed model for plain, twill, and "dutch" weaves. For losses through monofilament fabrics see G. C. Pedersen [*Filtr. Sep.* **11:** 586–589 (1975)]. For screens *inclined at an angle* θ, use the normal velocity component $V'$

$$V' = V\cos\theta \tag{6-109}$$

[P. J. D. Carothers and W. D. Baines, *J. Fluids Eng.* **97:** 116–117 (1975)] in place of $V$ in Eq. (6-109). This applies for Re > 500, $C = 1.26$, $\alpha \le 0.97$, and $0 < \theta < 45°$, for square-mesh screens and diamond-mesh netting. Screens inclined at an angle to the flow direction also experience a tangential stress.

For *nonnewtonian* fluids in creeping flow, frictional loss across a square-woven or full-twill-woven screen can be estimated by considering the screen as a set of parallel tubes, each of diameter equal to the average minimum opening between adjacent wires, and length twice the diameter, without entrance effects [J. F. Carley and W. C. Smith, *Polym. Eng. Sci.* **18:** 408–415 (1978)]. For screen stacks, the losses of individual screens should be summed.

## JET BEHAVIOR

A *free jet,* upon leaving an outlet, will entrain the surrounding fluid, expand, and decelerate. Total momentum is conserved as jet momentum is transferred to the entrained fluid. For practical purposes, a jet is considered free when its cross-sectional area is less than one-fifth of the total cross-sectional flow area of the region through which the jet is flowing [H. G. Elrod, *Heat. Piping Air Cond.* **26**(3): 149–155 (1954)], and the surrounding fluid is the same as the jet fluid. A *turbulent jet* in this discussion is considered to be a free jet issuing with Re > 2000. Additional discussion on the relation between Reynolds number and turbulence in jets is given by H. G. Elrod [*Heat. Piping Air Cond.* **26**(3): 149–155 (1954)]. G. N. Abramowitsch [*The Theory of Turbulent Jets,* MIT Press, Cambridge, Mass., 1963] and N. Rajaratnam [*Turbulent Jets,* Elsevier, Amsterdam, 1976] provide thorough discourses on turbulent jets. H. J. Hussein et al. [*J. Fluid Mech.* **258:** 31–75 (1994)] give extensive velocity data for a free jet, discussion of free jet experimentation, and comparison of data with momentum conservation equations.

A turbulent-free jet is normally considered to consist of four flow regions [G. L. Tuve, *Heat. Piping Air Cond.* **25**(1): 181–191 (1953); J. T. Davies, *Turbulence Phenomena,* Academic, New York, 1972, p. 93], as shown in Fig. 6-17:

1. Region of flow establishment, which is a short region of length about 6.4 nozzle diameters. The fluid in the conical core of the same length has a velocity about the same as the initial discharge velocity. The termination of this *potential core* occurs when the growing mixing (boundary) layer between the jet and the surroundings reaches the centerline of the jet.
2. A transition region that extends to about 8 nozzle diameters.
3. Region of established flow, which is the principal region of the jet. In this region, the velocity profile transverse to the jet is self-preserving when normalized by the decaying centerline velocity.
4. A terminal region where the residual centerline velocity reduces rapidly within a short distance. For air jets, the residual velocity will reduce to less than 0.3 m/s (1 ft/s), usually considered still air.

Several references quote 100 nozzle diameters for the length of the established flow region. However, this length is dependent on the initial velocity and Reynolds number.

Table 6-7 gives characteristics of *rounded-inlet circular jets* and *rounded-inlet infinitely wide slot jets* (aspect ratio > 15). The information in the table is for a homogeneous, incompressible air system under isothermal conditions. The table uses the following nomenclature:

$B_0$ = slot height
$D_0$ = circular nozzle opening
$q$ = total jet flow at distance $x$
$q_0$ = initial jet flow rate
$r$ = radius from circular jet centerline
$y$ = transverse distance from slot jet centerline
$V_c$ = centerline velocity
$V_r$ = circular jet velocity at $r$
$V_y$ = velocity at $y$

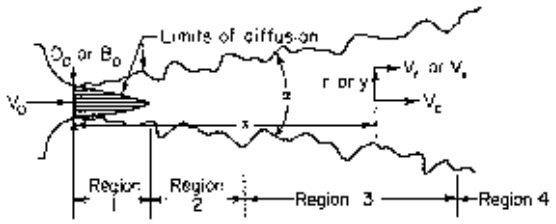

**FIG. 6-17** Configuration of a turbulent free jet.

P. O. Witze [*Am. Inst. Aeronaut. Astronaut. J.* **12:** 417–418 (1974)] gives equations for the centerline velocity decay of different types of subsonic and supersonic circular free jets. Entrainment of surrounding fluid in the region of flow establishment is lower than in the region of established flow [see B. J. Hill, *J. Fluid Mech.* **51:** 773–779 (1972)]. Data of M. B. Donald and H. Singer [*Trans. Inst. Chem. Eng.* (*London*), **37:** 255–267 (1959)] indicate that jet angle and the coefficients given in Table 6-5 depend upon the fluids; for a water system, the jet angle for a circular jet is 14° and the entrainment ratio is about 70 percent of that for an air system. Most likely these variations are due to Reynolds number effects which are not taken into account in Table 6-7. J. H. Rushton [*AIChE J.* **26:** 1038–1041 (1980)] examined available published results for circular jets and found that the centerline velocity decay is given by

$$\frac{V_c}{V_0} = 1.41\,\mathrm{Re}^{0.135}\left(\frac{D_0}{x}\right) \tag{6-110}$$

**TABLE 6-7 Turbulent Free-Jet Characteristics**

Where both jet fluid and entrained fluid are air

‡Albertson, Dai, Jensen, and Rouse, *Trans. Am. Soc. Civ. Eng.* **115:** 639–664 (1950), and Discussion, ibid., **115:** 665–697 (1950).

where $\mathrm{Re} = D_0V_0\rho/\mu$ is the initial jet Reynolds number. This result corresponds to a jet angle $\tan(\alpha/2)$ proportional to $\mathrm{Re}^{-0.135}$.

Characteristics of *rectangular jets* of various aspect ratios are given by H. G. Elrod [*Heat. Piping Air Cond.* **26**(3): 149–155 (1954)]. For *slot jets discharging into a moving fluid,* see A. S. Weinstein et al. [*J. Appl. Mech.* **23:** 437–443 (1967)]. *Coaxial jets* are discussed by W. Forstall and A. H. Shapiro [*J. Appl. Mech.* **17:** 399–408 (1950)], as are *double concentric jets* by N. A. Chigier and J. M. Beer [*J. Basic Eng.* **86:** 797–804 (1964)]. *Axisymmetric confined jets* are described by M. Barchilon and R. Curtet [*J. Basic Eng.* **86:** 777–787 (1964)]. *Restrained* turbulent jets of liquid discharging into air are described by J. T. Davies [*Turbulence Phenomena,* Academic, New York, 1972, p. 93]. These jets are inherently unstable and break up into drops after some distance. J. H. Lienhard and J. B. Day [*J. Basic Eng. Trans. ASME* pp. 515–522 (September 1970)] discuss the breakup of superheated liquid jets which flash upon discharge.

*Density gradients* affect the spread of a single-phase jet. A jet of lower density than the surroundings spreads more rapidly than a jet of the same density as the surroundings, and conversely, a denser jet spreads less rapidly. Additional details are given by W. R. Keagy and A. E. Weller [*Proc. Heat Transfer Fluid Mech. Inst.* ASME, pp. 89–98 (June 22–24, 1949)] and V. Cleeves and L. M. K. Boelter [*Chem. Eng. Prog.* **43:** 123–134 (1947)].

Few experimental data exist on *laminar jets* [see C. Gutfinger and R. Shinnar, *AIChE J.* **10:** 631–639 (1964)]. Theoretical analysis for velocity distributions and entrainment ratios in steady laminar flow is available in H. Schlichting and K. Gersten [*Boundary Layer Theory,* 8th ed rev., Springer-Verlag, Berlin, 2003] and in B. R. Morton [*Phys. Fluids* **10:** 2120–2127 (1967)]. The upper limit of the Reynolds number for stability of circular laminar jets may be in the range of 40 to 100. See, for example, P. J. Morris [*J. Fluid Mech.* **77:** 511–529 (1976)].

Theoretical analyses of jet flows for power law *nonnewtonian fluids* are given by J. Vlachopoulos and C. Stournaras [*AIChE J.* **21:** 385–388 (1975)], E. M. Mitwally [*J. Fluids Eng.* **100:** 363 (1978)], and K. Sridhar and G. W. Rankin [*J. Fluids Eng.* **100:** 500 (1978)].

## FLOW THROUGH ORIFICES

Section 10 of this handbook describes the use of orifice meters for flow measurement. In addition, **orifices** are commonly found within pipelines as flow-restricting devices, in perforated-pipe distribution and return manifolds, and in perforated plates. Incompressible flow through an orifice in a pipeline, as shown in Fig. 6-18, is commonly described by the following equation for flow rate $Q$ in terms of pressures $P_1$, $P_2$, and $P_3$; the orifice area $A_o$; the pipe cross-sectional area $A$; and the density $\rho$.

$$\begin{aligned} Q &= v_o A_o = C_o A_o \sqrt{\frac{2(P_1 - P_2)}{\rho[1 - (A_o/A)^2]}} \\ &= C_o A_o \sqrt{\frac{2(P_1 - P_3)}{\rho(1 - A_o/A)[1 - (A_o/A)^2]}} \end{aligned} \tag{6-111}$$

The velocity based on the hole area is $v_o$. Pressure $P_1$ is the pressure upstream of the orifice, typically about 1 pipe diameter upstream, pressure $P_2$ is the pressure at the *vena contracta,* where the flow passes through a minimum area which is less than the orifice area, and pressure $P_3$ is the pressure downstream of the vena contracta after pressure recovery associated with deceleration of the fluid. The velocity of approach factor $1 - (A_o/A)^2$ accounts for the kinetic energy approaching the orifice, and the *orifice coefficient* or *discharge coefficient* $C_o$ accounts for the vena contracta. The location of the vena contracta varies with $A_o/A$, but is about 0.7 pipe diameter for $A_o/A < 0.25$. The factor $1 - A_o/A$ accounts for pressure recovery. Pressure recovery is complete by about 4 to 8 pipe diameters downstream of the orifice. The permanent pressure drop is $P_1 - P_3$. When the orifice is at the end of pipe, discharging directly into a large chamber, there is negligible pressure recovery, the permanent pressure drop is $P_1 - P_2$, and the last equality in Eq. (6-111)

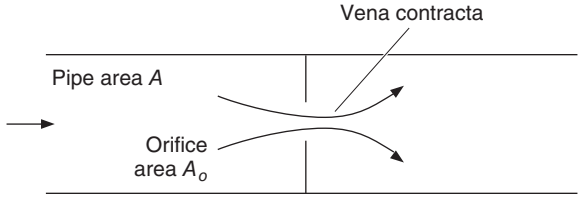

**FIG. 6-18** Flow through an orifice.

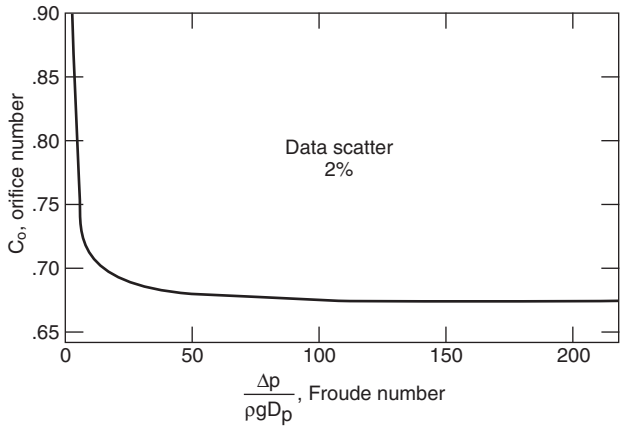

**FIG. 6-19** Orifice coefficient vs. Froude number. [*Courtesy E. I. duPont de Nemours & Co.*]

does not apply. Instead, $P_2 = P_3$. Equation (6-111) may also be used for flow across a perforated plate with open area $A_o$ and total area $A$. The location of the vena contracta and complete recovery would scale not with the vessel or pipe diameter in which the plate is installed, but with the hole diameter and pitch between holes.

The orifice coefficient has a value of about 0.62 at large Reynolds numbers ($\mathrm{Re} = D_o V_o \rho/\mu > 20{,}000$), although values ranging from 0.60 to 0.70 are frequently used. At lower Reynolds numbers, the orifice coefficient varies with both Re and the area or diameter ratio. See Sec. 10 for more details.

When liquids discharge vertically downward from a pipe of diameter $D_p$, through orifices into gas, gravity increases the discharge coefficient. Figure 6-19 shows this effect, giving the discharge coefficient in terms of a modified Froude number, $\mathrm{Fr} = \Delta p/(\rho g D_p)$.

The orifice coefficient deviates from its value for sharp-edged orifices when the orifice wall thickness exceeds about 75 percent of the orifice diameter. Some pressure recovery occurs within the orifice, and the orifice coefficient increases. Pressure drop across *segmental orifices* is roughly 10 percent greater than that for concentric circular orifices of the same open area.

## COMPRESSIBLE FLOW

Flows are typically considered *compressible* when the density varies by more than 5 to 10 percent. In practice, compressible flows are normally limited to gases, supercritical fluids, and multiphase flows containing gases. Liquid flows are normally considered incompressible, except for certain calculations involved in *hydraulic transient* analysis (see following) where compressibility effects are important even for nearly incompressible liquids. Texts on compressible gas flow include those by A. H. Shapiro [*Dynamics and Thermodynamics of Compressible Fluid Flow,* vols. 1 and 2, Ronald Press, New York, 1953] and M. J. Zucrow and J. D. Hoffman [*Gas Dynamics,* vols. 1 and 2, Wiley, New York, 1976]. The most important chemical process applications of compressible flow are one-dimensional gas flows through nozzles or orifices and in pipelines. Multidimensional external flows are of interest mainly in aerodynamic applications.

**Mach Number and Speed of Sound** The *Mach number* $M = V/c$ is the ratio of fluid velocity $V$ to the *speed of sound* or *acoustic velocity* $c$. The speed of sound is the propagation velocity of infinitesimal pressure disturbances and is derived from a momentum balance. The compression caused by the pressure wave is adiabatic and frictionless, and therefore isentropic.

$$c = \sqrt{\left(\frac{\partial p}{\partial \rho}\right)_s} \tag{6-112}$$

The partial derivative is taken at constant entropy $s$. For a perfect gas (ideal gas with constant heat capacity)

$$\left(\frac{\partial p}{\partial \rho}\right)_s = \frac{kRT}{M_w} \tag{6-113}$$

where $k$ = ratio of specific heats, $C_p/C_v$
$R$ = universal gas constant (8314 J/kgmol · K)
$T$ = absolute temperature
$M_w$ = molecular weight

Hence for a perfect gas,

$$c = \sqrt{\frac{kRT}{M_w}} \tag{6-114}$$

The Mach number is calculated by using the speed of sound evaluated at the local pressure and temperature. When $M = 1$, the flow is *critical* or *sonic,* and the velocity equals the local speed of sound. For *subsonic* flows, $M < 1$ while *supersonic* flows have $M > 1$. Compressibility effects are always important when the Mach number exceeds 0.1 to 0.2, but they may be important at lower Mach number; large density changes can occur in long pipelines at low velocity, for example.

**Isothermal Gas Flow in Pipes and Channels** Isothermal compressible flow is often approximated in long transport lines. Mach numbers are usually small, yet compressibility effects are important when the total pressure drop is a significant fraction of the absolute pressure. For an ideal gas, integration of the differential form of the momentum or mechanical energy balance equations, assuming a constant friction factor $f$ over a length $L$ of a channel of constant cross section and hydraulic diameter $D_H$, yields

$$p_1^2 - p_2^2 = G^2 \frac{RT}{M_w}\left[\frac{4fL}{D_H} + 2\ln\left(\frac{p_1}{p_2}\right)\right] \tag{6-115}$$

where the mass velocity $G = w/A = \rho V$ is the mass flow rate per unit cross-sectional area of the channel. The logarithmic term on the right-hand side accounts for the pressure change caused by acceleration of gas as its density decreases, while the first term is equivalent to the calculation of frictional losses using the density evaluated at the average pressure $(p_1 + p_2)/2$.

Solution of Eq. (6-115) for $G$ and differentiation with respect to $p_2$ reveal a maximum mass flux $G_{\max} = p_2\sqrt{M_w/(RT)}$ and a corresponding exit velocity $V_{2,\max} = \sqrt{RT/M_w}$ and exit Mach number $M_2 = 1/\sqrt{k}$. This apparent *choking* condition is not physically meaningful because at such high velocities, and high rates of expansion, isothermal conditions are not maintained.

**Adiabatic Frictionless Nozzle Flow** In process plant pipelines, compressible flows are usually more nearly adiabatic than isothermal. Solutions for adiabatic flows through frictionless nozzles and in channels with constant cross section and constant friction factor are readily available.

Figure 6-20 illustrates adiabatic discharge of a perfect gas through a frictionless nozzle from a large chamber where velocity is effectively zero. The subscript 0 refers to the *stagnation* conditions in the chamber. More generally, stagnation conditions are the conditions that would be obtained by isentropically decelerating a gas flow to zero velocity. The minimum area section, or *throat,* of the nozzle is at the nozzle exit. The flow through the nozzle is isentropic because it is assumed frictionless (reversible) and adiabatic. In terms of the exit Mach number $M_1$, the following ratios between stagnation and exit conditions occur.

$$\frac{p_0}{p_1} = \left(1 + \frac{k-1}{2}M_1^2\right)^{k/(k-1)} \tag{6-116}$$

$$\frac{T_0}{T_1} = 1 + \frac{k-1}{2}M_1^2 \tag{6-117}$$

$$\frac{\rho_0}{\rho_1} = \left(1 + \frac{k-1}{2}M_1^2\right)^{1/(k-1)} \tag{6-118}$$

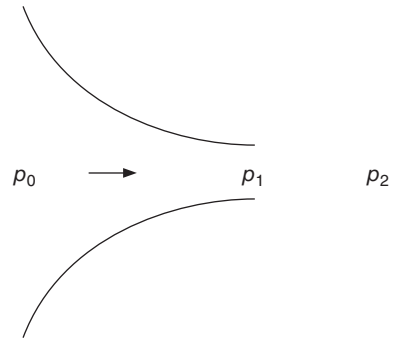

**FIG. 6-20** Isentropic flow through a nozzle.

The mass velocity $G = w/A$ at the nozzle exit is given by

$$G = p_0\sqrt{\frac{kM_w}{RT_0}}\frac{M_1}{\left(1+\frac{k-1}{2}M_1^2\right)^{(k+1)/2(k-1)}} \tag{6-119}$$

These equations are consistent with the isentropic relations for a perfect gas $p/p_0 = (\rho/\rho_0)^k$, $T/T_0 = (p/p_0)^{(k-1)/k}$. Equation (6-117) is valid for adiabatic flows with or without friction; it does not require isentropic flow. Equations (6-116), (6-118), and (6-119) do require isentropic flow.

The *exit Mach number $M_1$ may not exceed unity.* At $M_1 = 1$, the flow is said to be *choked, sonic,* or *critical.* When the flow is choked, the pressure at the exit is greater than the pressure of the surroundings into which the gas flow discharges. The pressure drops from the exit pressure to the pressure of the surroundings in the jet beyond the nozzle exit. Sonic flow conditions are denoted by *; sonic exit conditions are found by substituting $M_1 = M_1{}^* = 1$ into Eqs. (6-116) to (6-119).

$$\frac{p^*}{p_0} = \left(\frac{2}{k+1}\right)^{k/(k-1)} \tag{6-120}$$

$$\frac{T^*}{T_0} = \frac{2}{k+1} \tag{6-121}$$

$$\frac{\rho^*}{\rho_0} = \left(\frac{2}{k+1}\right)^{1/(k-1)} \tag{6-122}$$

$$G^* = p_0\sqrt{\left(\frac{2}{k+1}\right)^{(k+1)/(k-1)}\left(\frac{kM_w}{RT_0}\right)} \tag{6-123}$$

Under choked conditions, the exit velocity is $V = V^* = c^* = \sqrt{kRT^*/M_w}$, with sonic velocity evaluated at the exit temperature. For air ($k = 1.4$) the critical pressure ratio $p^*/p_0$ is 0.5283 and the critical temperature ratio $T^*/T_0 = 0.8333$. Thus, for air discharging from 300 K, the temperature drops by 50 K in accelerating to sonic velocity. This large temperature decrease results from the conversion of enthalpy into kinetic energy. With sufficient humidity, condensation could occur, invalidating the perfect gas analysis. As the discharged jet decelerates in the external stagnant gas, it recovers its initial enthalpy.

To determine the discharge conditions and rate through a nozzle from upstream pressure $p_0$ to external pressure $p_2$, as shown in Fig. 6-20, Eqs. (6-116) through (6-123) are used as follows. The critical pressure is first determined from Eq. (6-120). If $p_2 > p^*$, then the flow is subsonic (subcritical, unchoked). Then $p_1 = p_2$ and $M_1$ may be obtained from Eq. (6-116). Substitution of $M_1$ into Eqs. (6-117) through (6-120) then gives the exit temperature, density, and mass velocity. The exit velocity can be obtained from $V_1 = G/\rho_1$ or $V_1 = M_1c_1$ with $c_1$ evaluated at $T_1$.

On the other hand, if $p_2 \le p^*$, then the flow is choked, $M_1 = 1$, and $p_1 = p^*$. The temperature and density, respectively, are equal to $T^*$ and $\rho^*$ from Eqs. (6-121) and (6-122); the mass velocity is $G^*$ obtained from Eq. (6-123). When the flow is choked, $G = G^*$ is independent of external downstream pressure. Reducing the downstream pressure will not increase the flow. The mass flow rate under choking conditions is directly proportional to the upstream pressure $p_0$.

***Example 6-7 Flow Through Frictionless Nozzle*** Dry air at temperature $T_0 = 293$ K discharges through a frictionless nozzle to atmospheric pressure. Compute the discharge mass flux $G$, pressure, temperature, Mach number, and velocity at the exit. Consider two cases: (1) $p_0 = 7.0 \times 10^5$ Pa absolute and (2) $p_0 = 1.5 \times 10^5$ Pa absolute.

1. $p_0 = 7.0 \times 10^5$ Pa. For air with $k = 1.4$, the critical pressure ratio from Eq. (6-120) is $p^*/p_0 = 0.5283$ and $p^* = 0.5283 \times 7.0 \times 10^5 = 3.70 \times 10^5$ Pa. Since this is greater than the external atmospheric pressure $p_2 = 1.01 \times 10^5$ Pa, the flow is choked and the exit pressure is $p_1 = 3.70 \times 10^5$ Pa. The exit Mach number is 1.0, and the mass flux is equal to $G^*$, given by Eq. (6-123).

$$G^* = 7.0\times10^5 \times \sqrt{\left(\frac{2}{1.4+1}\right)^{(1.4+1)/(1.4-1)}\left(\frac{1.4\times29}{8314\times293}\right)} = 1650 \text{ kg/m}^2\cdot\text{s}$$

The exit temperature, because the flow is choked, is

$$T^* = \left(\frac{T^*}{T_0}\right)T_0 = \left(\frac{2}{1.4+1}\right)\times293 = 244 \text{ K}$$

The exit velocity is $V = Mc = c^* = \sqrt{kRT^*/M_w} = 313$ m/s.

2. $p_0 = 1.5 \times 10^5$ Pa. In this case $p^* = 0.79 \times 10^5$ Pa, which is less than $p_2$. Hence, $p_1 = p_2 = 1.01 \times 10^5$ Pa. The flow is unchoked (subsonic). Equation (6-116) is solved for the Mach number.

$$\frac{1.5\times10^5}{1.01\times10^5} = \left(1+\frac{1.4-1}{2}M_1^2\right)^{1.4/(1.4-1)}$$
$$M_1 = 0.773$$

Substitution into Eq. (6-119) gives $G$.

$$G = 1.5\times10^5\times\sqrt{\frac{1.4\times29}{8,314\times293}} \times\frac{0.773}{\left(1+\left(\frac{1.4-1}{2}\right)\times0.773^2\right)^{(1.4+1)/2(1.4-1)}} = 337 \text{ kg/m}^2\cdot\text{s}$$

The exit temperature is found from Eq. (6-117) to be 261.6 K. The exit velocity is

$$V = Mc = 0.773\times\sqrt{\frac{1.4\times8314\times261.6}{29}} = 250 \text{ m/s}$$

**Adiabatic Flow with Friction in a Duct of Constant Cross Section** Integration of the differential forms of the continuity, momentum, and total energy equations for a perfect gas, assuming a constant friction factor, leads to a set of simultaneous algebraic equations. These may be found in A. H. Shapiro [*Dynamics and Thermodynamics of Compressible Fluid Flow,* vols. 1 and 2, Ronald Press, New York, 1953] or M. J. Zucrow and J. D. Hoffman [*Gas Dynamics,* vols. 1 and 2, Wiley, New York, 1976]. C. E. Lapple's [*Trans. AIChE.* **39:** 395–432 (1943)] widely cited graphical presentation of the solution of these equations contained a subtle error, which was corrected by O. Levenspiel [*AIChE J.* **23:** 402–403 (1977)]. Levenspiel's graphical solutions are presented in Fig. 6-21. These charts refer to the physical situation illustrated in Fig. 6-22, where a perfect gas discharges from stagnation conditions in a large chamber through an isentropic nozzle followed by a duct of length $L$. The resistance parameter is $N = 4fL/D_H$, where $f$ = Fanning friction factor and $D_H$ = hydraulic diameter.

The exit Mach number $M_2$ may not exceed unity. $M_2 = 1$ corresponds to choked flow; sonic conditions may exist only at the pipe exit. The mass velocity $G^*$ in the charts is the choked *mass flux for an isentropic nozzle* given by Eq. (6-123). For a pipe of finite length, the mass flux is less than $G^*$ under choking conditions. The curves in Fig. 6-21 become vertical at the choking point, where flow becomes independent of downstream pressure.

The equations for nozzle flow, Eqs. (6-116) through (6-119), remain valid for the nozzle section even in the presence of the discharge pipe. The graphs in Fig. 6-21 are based on accurate calculations, but are difficult to interpolate precisely. While they are quite useful for qualitative insight and rough estimates, precise calculations are best done using the equations for one-dimensional adiabatic flow with friction, which are suitable for computer programming. Let subscripts 1 and 2 denote two points along a pipe of diameter $D$, point 2 being downstream of point 1. From a given point in the pipe, where the Mach number is $M$, the additional length of pipe required to accelerate the flow to sonic velocity ($M = 1$) is denoted $L_{max}$ and may be computed from

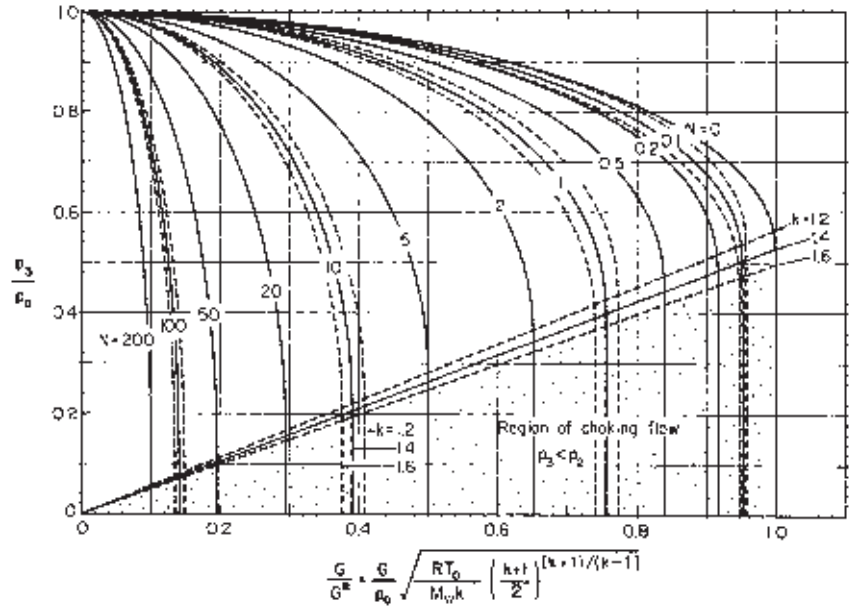
$$\frac{4fL_{max}}{D_H} = \frac{1-M^2}{kM^2} + \frac{k+1}{2k}\ln\left(\frac{\frac{k+1}{2}M^2}{1+\frac{k-1}{2}M^2}\right) \tag{6-124}$$

With $L$ = length of pipe between points 1 and 2, the change in Mach number may be computed from

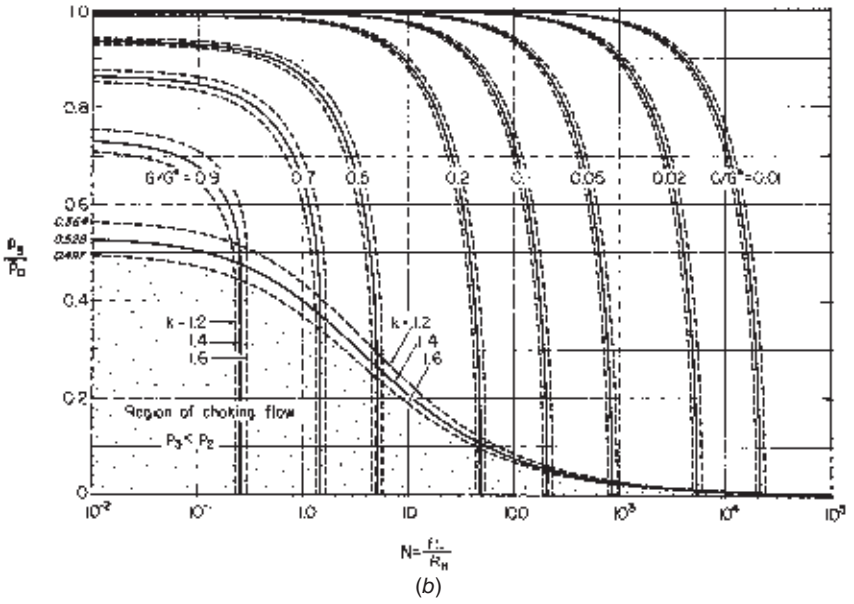
$$\frac{4fL}{D_H} = \left(\frac{4fL_{max}}{D}\right)_1 - \left(\frac{4fL_{max}}{D}\right)_2 \tag{6-125}$$

and the pressures $p_1$ and $p_2$ are related to the pressure $p^*$ where $M = 1$ by

$$\frac{p}{p^*} = \frac{1}{M}\sqrt{\frac{k+1}{2\left(1+\frac{k-1}{2}M^2\right)}} \tag{6-126}$$



(*a*)



(*b*)

**FIG. 6-21** Design charts for adiabatic flow of gases (*a*) useful for finding the allowable pipe length for given flow rate; (*b*) useful for finding the discharge rate in a given piping system. [From O. Levenspiel, *Am. Inst. Chem. Eng. J.*, **23:** 402 (1977).]

The additional frictional losses due to pipe fittings such as elbows may be added to the velocity head loss $N = 4fL/D_H$, using the same velocity head loss values as for incompressible flow. This works well for fittings that do not significantly reduce the channel cross-sectional area, but may cause large errors when the flow area is greatly reduced, for example, by restricting orifices. Compressible flow across restricting orifices is discussed in Sec. 10 of this handbook. An elbow near the exit of a pipeline may choke the flow even though the Mach number is less than unity due to the nonuniform velocity profile in the elbow. For an abrupt contraction rather than rounded nozzle inlet, an additional 0.5 velocity head should be added to *N*. This is a reasonable approximation for determining *G*, but note that it allocates the additional losses to the pipeline, even though they are actually incurred in the entrance. Do not include one velocity head exit loss in *N*. The kinetic energy at the exit is already accounted for in the integration of the balance equations.

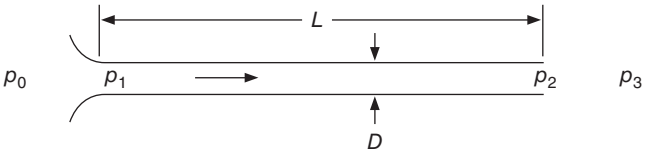


**FIG. 6-22** Adiabatic compressible flow in a pipe with a well-rounded entrance.

***Example 6-8 Compressible Flow with Friction Losses*** Calculate the discharge rate of air to the atmosphere from a reservoir at $10^6$ Pa gauge and 20°C through 10 m of straight 2-in Schedule 40 steel pipe (inside diameter = 0.0525 m), and three 90° elbows. Assume 0.5 velocity head is lost for the elbows.

For commercial steel pipe, with a roughness of 0.046 mm, the friction factor for fully rough flow is about 0.00476, from Eq. (6-38). It remains to be verified that the Reynolds number is sufficiently large to assume fully rough flow. Assuming an abrupt entrance with 0.5 velocity head lost,

$$N = 4 \times 0.00476 \times \frac{10}{0.0525} + 0.5 + 3 \times 0.5 = 5.6$$

The pressure ratio $p_3/p_0$ is

$$\frac{1.01 \times 10^5}{1 \times 10^6 + 1.01 \times 10^5} = 0.092$$

From Fig. 6-21*a* at $N = 5.6$, $p_3/p_0 = 0.092$, and $k = 1.4$ for air, the flow is seen to be choked. At the choke point with $N = 5.6$ the critical pressure ratio $p_2/p_0$ is about 0.25 and $G/G^*$ is about 0.48. Equation (6-123) gives

$$G^* = 1.101 \times 10^6 \sqrt{\left(\frac{2}{1.4+1}\right)^{(1.4+1)/(1.4-1)} \left(\frac{1.4 \times 29}{8,314 \times 293.15}\right)} = 2600 \text{ kg/m}^2 \cdot \text{s}$$

Multiplying by $G/G^* = 0.48$ yields $G = 1250$ kg/m$^2 \cdot$ s. The discharge rate is $w = GA = 1250 \times \pi \times 0.0525^2/4 = 2.7$ kg/s. Numerical solution based on the isentropic nozzle equations and Eqs. (6-124) through (6-126) for the pipe gives $w = 2.71$ kg/s.

Before this solution is accepted, the Reynolds number should be checked. At the pipe exit, the temperature is given by Eq. (6-121) since the flow is choked. $T_2 = T^* = 244.6$ K. The viscosity of air at this temperature is about $1.6 \times 10^{-5}$ Pa $\cdot$ s. Then

$$\text{Re} = \frac{DV\rho}{\mu} = \frac{DG}{\mu} = \frac{0.0525 \times 1,250}{1.6 \times 10^{-5}} = 4.1 \times 10^6$$

At the beginning of the pipe, the temperature is greater, giving greater viscosity and a Reynolds number of $3.6 \times 10^6$. Over the entire pipe length, the Reynolds number is very large and the complete turbulence friction factor choice was indeed valid.

Once the mass flux $G$ has been determined, Fig. 6-21*a* or 6-21*b* or Eqs. (6-124) through (6-126) can be used to determine the pressure at any point along the pipe.

**Convergent/Divergent Nozzles (De Laval Nozzles)** During frictionless adiabatic one-dimensional flow with changing cross-sectional area $A$, the following relations are obeyed:

$$\frac{dA}{A} = \frac{dp}{\rho V^2}(1 - M^2) = \frac{1 - M^2}{M^2}\frac{d\rho}{\rho} = -(1 - M^2)\frac{dV}{V} \tag{6-127}$$

Equation (6-127) implies that in converging channels, subsonic flows are accelerated and the pressure and density decrease. In diverging channels, subsonic flows are decelerated as the pressure and density increase. In supersonic flows, the opposite is true. Diverging channels accelerate the flow, while converging channels decelerate the flow.

Figure 6-23 shows a converging/diverging nozzle. When $p_2/p_0$ is less than the critical pressure ratio ($p^*/p_0$), the flow will be subsonic in the converging portion of the nozzle, sonic at the throat, and supersonic in the diverging portion. At the throat, where the flow is critical and the velocity is sonic, the area is denoted $A^*$. The cross-sectional area and pressure vary with Mach number along the converging/diverging flow path according to the following equations for isentropic flow of a perfect gas:

$$\frac{A}{A^*} = \frac{1}{M}\left[\frac{2}{k+1}\left(1 + \frac{k-1}{2}M^2\right)\right]^{(k+1)/2(k-1)} \tag{6-128}$$

$$\frac{p_0}{p} = \left(1 + \frac{k-1}{2}M^2\right)^{k/(k-1)} \tag{6-129}$$

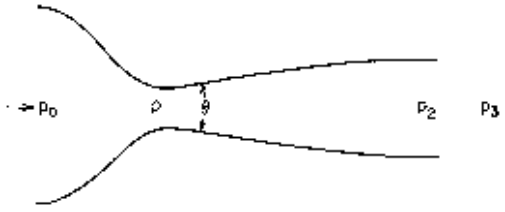

**FIG. 6-23** Converging/diverging nozzle.

The temperature obeys the adiabatic flow equation for a perfect gas

$$\frac{T_0}{T} = 1 + \frac{k-1}{2}M^2 \tag{6-130}$$

Equation (6-130) does not require frictionless (isentropic) flow. The sonic mass flux through the throat is given by Eq. (6-123). With $A$ set equal to the nozzle exit area, the exit Mach number, pressure, and temperature may be calculated. Only if the exit pressure equals the ambient discharge pressure is the maximum possible expansion velocity reached in the nozzle. Expansion will be incomplete if the exit pressure exceeds the ambient discharge pressure. If the calculated exit pressure is less than the ambient discharge pressure, the nozzle is overexpanded and shocks within the expanding portion will result.

The shape of the converging section is a smooth trumpet shape similar to the simple converging nozzle. Special shapes of the diverging section are required to produce the maximum supersonic exit velocity. Shocks result if the divergence is too rapid, and excessive boundary layer friction occurs if the divergence is too shallow. See H. W. Liepmann and A. Roshko [*Elements of Gas Dynamics,* Wiley, New York, 1957, p. 284]. If the nozzle is to be used as a thrust device, the diverging section can be conical with a total included angle of 30° [G. P. Sutton and O. Biblarz, *Rocket Propulsion Elements,* 9th ed., Wiley, Hoboken, N.J., 2017]. To obtain large exit Mach numbers, slot-shaped rather than axisymmetric nozzles are used.

## MULTIPHASE FLOW

Multiphase flows, even when restricted to simple pipeline geometry, are in general quite complex, with several features making them more complicated than single-phase flow. Flow pattern description is not merely an identification of laminar or turbulent flow. The relative quantities of the phases and the topology of the interfaces must be described. Because of phase density differences, vertical flow patterns are different from horizontal flow patterns, and horizontal flows are usually asymmetric. Even when phase equilibrium is achieved by good mixing in two-phase flow, the changing equilibrium state as pressure drops with distance, or as heat is added or lost, may require that interphase mass transfer, and changes in the relative amounts of the phases, be considered. C. T. Crowe [ed., *Multiphase Flow Handbook*, CRC Press, Boca Raton, Fla., 2006] presents multiphase flow fundamentals as well as information on flow in pipelines and process equipment.

G. B. Wallis [*One-dimensional Two-phase Flow,* McGraw-Hill, New York, 1969] and G. W. Govier and K. Aziz [*The Flow of Complex Mixtures in Pipes*, Krieger, Huntington, N.Y., 1977] present one-dimensional mass, momentum, mechanical energy, and total energy balance equations for two-phase flows. Such equations, for the most part, are used as a framework in which to interpret experimental data. Reliable prediction of multiphase flow behavior generally requires use of data or correlations. *Two-fluid modeling,* in which three-dimensional partial differential equations of motion are written for each phase, treating each as a continuum, occupying a volume fraction which is a continuous function of position, is a developing technique made possible by improved computational methods. For some relatively simple examples not requiring numerical computation, see J. R. A. Pearson [*Chem. Engr. Sci.* **49:** 727–732 (1994)]. Constitutive equations for two-fluid models are not yet sufficiently robust for accurate general-purpose two-phase flow computation, but may be quite good for particular classes of flows.

**Liquids and Gases** For cocurrent flow of liquids and gases in vertical (upflow), horizontal, and inclined pipes, a very large literature of experimental and theoretical work has been published, with less work on countercurrent and cocurrent vertical downflow. Much of the effort has been devoted to predicting flow patterns, pressure drop, and volume fractions of the phases, with emphasis on fully developed flow. In practice, many two-phase flows in process plants are not fully developed.

The most reliable methods for fully developed gas/liquid flows use *mechanistic models* to predict flow pattern, and they use different pressure drop and void fraction estimation procedures for each flow pattern. Such methods are too lengthy to include here and are well suited to incorporation into computer programs; commercial codes for gas/liquid pipeline flows are available. Some key references for mechanistic methods for flow pattern transitions and flow regime–specific pressure drop and void fraction methods include Y. Taitel and A. E. Dukler [*AIChE J.* **22:** 47–55 (1976)], D. Barnea et al. [*Int. J. Multiphase Flow* **6:** 217–225 (1980)], D. Barnea [*Int. J. Multiphase Flow* **12:** 733–744 (1986)], Y. Taitel et al. [*AIChE J.* **26:** 345–354 (1980)], G. B. Wallis [*One-dimensional Two-phase Flow,* McGraw-Hill, New York, 1969], and A. E. Dukler and M. G. Hubbard [*Ind. Eng. Chem. Fundam.* **14:** 337–347 (1975)]. See R. V. A. Oliemans and B. F. Pots in C. T. Crowe [ed., *Multiphase Flow Handbook*, CRC Press, Boca Raton, Fla., 2006] for a recent summary. For preliminary or approximate calculations, *flow pattern maps* and flow regime–independent empirical correlations are simpler and faster to use. Such methods for horizontal and vertical flows are provided in the following.

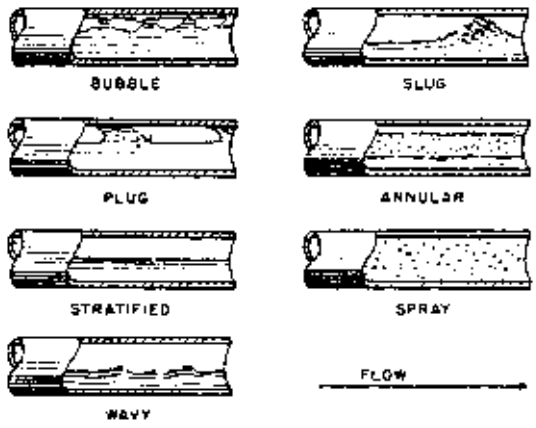

**FIG. 6-24** Gas/liquid flow patterns in horizontal pipes. [From G. E. Alves, *Chem. Eng. Progr.,* **50**, 449–456 (1954).]

In *horizontal pipe,* flow patterns for fully developed flow have been reported in numerous studies. Transitions between flow patterns are gradual, and subjective owing to the visual interpretation of individual investigators. In some cases, statistical analysis of pressure fluctuations has been used to distinguish flow patterns. Figure 6-24 [G. E. Alves, *Chem. Eng. Progr.* **50:** 449–456 (1954)] shows seven flow patterns for horizontal gas/liquid flow. *Bubble flow* is prevalent at high ratios of liquid to gas flow rates. The gas is dispersed as bubbles which move at velocity similar to that of the liquid and tend to concentrate near the top of the pipe at lower liquid velocities. *Plug flow* describes a pattern in which alternate plugs of gas and liquid move along the upper part of the pipe. In *stratified flow,* the liquid flows along the bottom of the pipe, and the gas flows over a smooth liquid/gas interface. Similar to stratified flow, *wavy flow* occurs at greater gas velocities and has waves moving in the flow direction. When wave crests are sufficiently high to bridge the pipe, they form frothy slugs which move at much greater than the average liquid velocity. *Slug flow* can cause severe and sometimes dangerous vibrations in equipment because of impact of the high-velocity slugs against bends or other fittings. Slugs may also flood gas/liquid separation equipment.

In *annular flow,* liquid flows as a thin film along the pipe wall and gas flows in the core. Some liquid is entrained as droplets in the gas core. At very high gas velocities, nearly all the liquid is entrained as small droplets. This pattern is called *spray, dispersed,* or *mist flow.*

Approximate prediction of flow pattern may be quickly done using *flow pattern maps,* an example of which is shown in Fig. 6-25 [O. Baker, *Oil Gas J.* **53**(12): 185–190, 192–195 (1954)]. The Baker chart remains widely used; however, for critical calculations, the mechanistic model methods referenced previously or commercial software based on large proprietary databases, are generally preferred for their greater accuracy, especially for large pipe diameters and fluids with physical properties different from air/water at atmospheric pressure. In the chart,

$$\lambda = (\rho'_G \rho'_L)^{1/2} \tag{6-131}$$

$$\psi = \frac{1}{\sigma'}\left[\frac{\mu'_L}{(\rho'_L)^2}\right]^{1/3} \tag{6-132}$$

Here $G_L$ and $G_G$ are the liquid and gas mass velocities, respectively, $\mu'_L$ is the ratio of liquid viscosity to water viscosity, $\rho'_G$ is the ratio of gas density to air density, $\rho'_L$ is the ratio of liquid density to water density, and $\sigma'$ is the ratio of liquid surface tension to water surface tension. The reference properties are at 20°C and atmospheric pressure, water density 1000 kg/m$^3$ (62.3 lbm/ft$^3$), air density 1.20 kg/m$^3$ (0.075 lbm/ft$^3$), water viscosity 0.001 Pa · s (1 cP), and surface tension 0.073 N/m (73 dyn/cm). The empirical parameters $\lambda$ and $\psi$ provide a crude accounting for physical properties. The Baker chart is dimensionally inconsistent since the dimensional quantity $G_G/\lambda$ is plotted versus a dimensionless one, $G_L\lambda\psi/G_G$, and so must be used with $G_G$ in lbm/(ft$^2$ · s) units on the ordinate. To convert to kg/(m$^2$ · s), multiply by 4.8824.

Approximate predictions of *pressure drop* for fully developed, incompressible horizontal gas/liquid flow may be made by using the method of R. W. Lockhart and R. C. Martinelli [*Chem. Eng. Prog.* **45:** 39–48 (1949)]. First, the pressure drops that would be expected for each of the two phases as if flowing alone in single-phase flow are calculated. The Lockhart-Martinelli parameter $X$ is

$$X = \left[\frac{(\Delta p/L)_L}{(\Delta p/L)_G}\right]^{1/2} \tag{6-133}$$

The two-phase pressure drop may then be estimated from either of the single-phase pressure drops, using

$$\left(\frac{\Delta p}{L}\right)_{TP} = Y_L\left(\frac{\Delta p}{L}\right)_L \tag{6-134}$$

or

$$\left(\frac{\Delta p}{L}\right)_{TP} = Y_G\left(\frac{\Delta p}{L}\right)_G \tag{6-135}$$

where $Y_L$ and $Y_G$ are read from Fig. 6-26 as functions of $X$. The curve labels refer to the flow regime (laminar or turbulent) found for each of the phases flowing alone. In Fig. 6-26, the original curves for liquid viscous/gas turbulent and liquid turbulent/gas viscous have been collapsed onto a single curve. The $Y_G$ curves are well fit by the following equation [J. O. Wilkes, *Fluid Mechanics for Chemical Engineers*, 2d ed., Prentice-Hall, Upper Saddle River, N.J., 2006].

$$Y_G = (1 + X^{2/n})^n \tag{6-136}$$

where the value of $n$ is given in Table 6-8. Note that $Y_L = Y_G/X^2$.

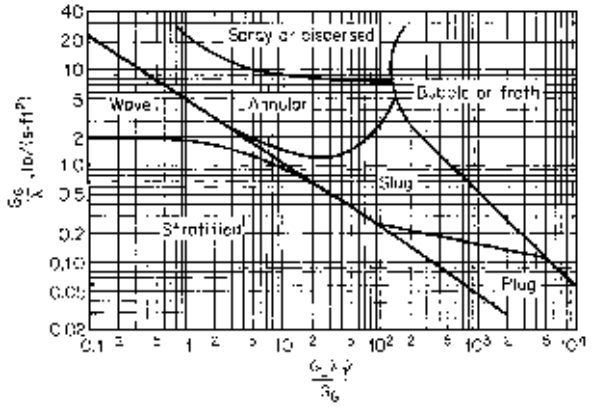

**FIG. 6-25** Flow-pattern regions in cocurrent liquid/gas flow through horizontal pipes. To convert lbm/(ft$^2$ · s) to kg/(m$^2$ · s), multiply by 4.8824. [From O. Baker, *Oil Gas J.,* **53**[12], 185–190, 192, 195 (1954).]

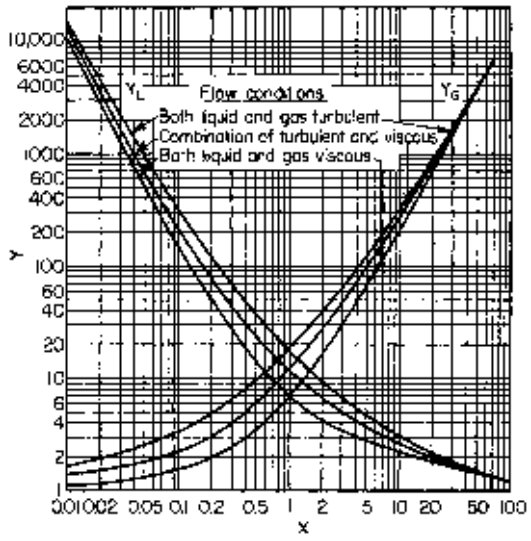

**FIG. 6-26** Parameters for pressure drop in liquid/gas flow through horizontal pipes. [Based on R. W. Lockhart and R. C. Martinelli, *Chem. Engr. Prog.*, **45,** 39 (1949).]

**TABLE 6-8 Parameter *n* for Lockhart-Martinelli Correlation**

| | Liquid | Gas | *n* |
|---|---|---|---|
| | Turbulent | Turbulent | 4.12 |
| | Viscous | Turbulent | 3.61 |
| | Turbulent | Viscous | 3.56 |
| $X < 1$ | Viscous | Viscous | 2.68 |
| $X > 1$ | Viscous | Viscous | 3.27 |

R. W. Lockhart and R. C. Martinelli [*Chem. Eng. Prog.* **45:** 39–48 (1949)] correlated pressure drop data from pipes 25 mm in diameter or less within about ±50 percent. In general, the predictions are high for stratified, wavy, and slug flows and low for annular flow. The correlation can be applied to pipe diameters up to about 0.1 m (4 in) with about the same accuracy.

The *volume fraction,* sometimes called *holdup,* of each phase in two-phase flow is generally not equal to its volumetric flow rate fraction, because of velocity differences, or *slip,* between the phases. For each phase, denoted by subscript *i,* the relations among superficial velocity $V_i$, in situ velocity $\upsilon_i$, volume fraction $R_i$, phase volumetric flow rate $Q_i$, and pipe area $A$ are

$$Q_i = V_i A = \nu_i R_i A \tag{6-137}$$

$$\nu_i = \frac{V_i}{R_i} \tag{6-138}$$

The *slip velocity* between gas and liquid is $\upsilon_s = \upsilon_G - \upsilon_L$. For two-phase gas/liquid flow, $R_L + R_G = 1$.

For fully developed incompressible horizontal gas/liquid flow, a quick estimate for $R_L$ may be obtained from Fig. 6-27, as a function of the Lockhart-Martinelli parameter $X$. Indications are that liquid volume fractions may be overpredicted for liquids more viscous than water [G. E. Alves, *Chem. Eng. Progr.* **50:** 449–456 (1954)] and underpredicted for pipes larger than 25-mm diameter [O. Baker, *Oil Gas J.* **53**(12): 185–190, 192–195 (1954)]. J. O. Wilkes [*Fluid Mechanics for Chemical Engineers*, 2d ed., Prentice-Hall, Upper Saddle River, N.J., 2006] provides an estimate for $R_L$ as a function of the Lockhart-Martinelli parameter.

$$R_L = 1 - \frac{1}{(1 + 0.0904 X^{0.548})^{2.82}} \tag{6-139}$$

A method for predicting pressure drop and volume fraction for *nonnewtonian fluids* in annular flow has been proposed by F. G. Eisenberg and C. B. Weinberger [*AIChE J.* **25:** 240–245 (1979)]. S. K. Das et al. [*Can. J. Chem. Eng.* **70:** 431–437 (1992)] studied holdup in both horizontal and vertical gas/liquid flow with nonnewtonian liquids. S. I. Farooqi and J. F. Richardson [*Trans. Inst. Chem. Engrs.* **60:** 292–305, 323–333 (1982)] developed correlations for holdup and pressure drop for gas/nonnewtonian liquid horizontal flow. They used a modified Lockhart-Martinelli parameter for nonnewtonian liquid holdup. They found that two-phase pressure drop may actually be less than the single-phase liquid pressure drop with shear-thinning liquids in laminar flow.

Pressure drop data for a 1-in *feed tee* with the liquid entering the run and gas entering the branch are given by G. E. Alves [*Chem. Eng. Progr.* **50:** 449–456 (1954)]. Pressure drop and division of two-phase *annular flow in a tee* are discussed by A. E. Fouda and E. Rhodes [*Trans. Inst. Chem. Eng.* [*London*], **52:** 354–360 (1974)]. Flow through tees can result in unexpected flow splitting. Further reading on gas/liquid flow through tees may be found in R. F. Mudde et al. [*Int. J. Multiphase Flow* **19:** 563–573 (1993)], R. I. Issa and P. J. Oliveira [*Computers and Fluids* **23:** 347–372 (1994)], and B. J. Azzopardi and P. A. Smith [*Int. J. Multiphase Flow* **18:** 861–875 (1992)].

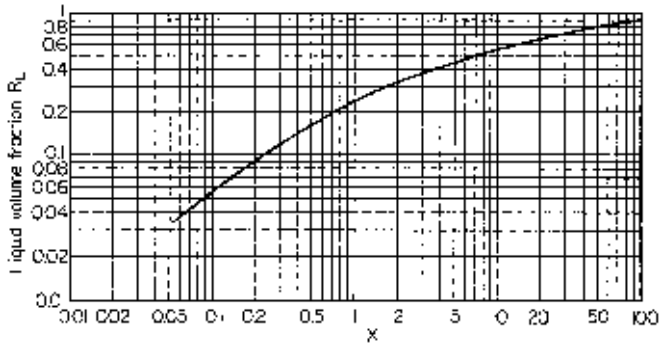

**FIG. 6-27** Liquid volume fraction in liquid/gas flow through horizontal pipes. [From Lockhart and Martinelli, *Chem. Engr. Prog.*, **45,** 39 (1949).]

Results by J. M. Chenoweth and M. W. Martin [*Pet. Refiner* **34**(10): 151–155 (1955)] indicate that single-phase data for *fittings* and *valves* can be used in their correlation for two-phase pressure drop. L. T. Smith et al. [*J. Eng. Power* **99:** 343–347 (1977)] evaluated correlations for two-phase flow of steam/water and other gas/liquid mixtures through sharp-edged *orifices* meeting ASTM standards for flow measurement. The correlation of J. W. Murdock [*J. Basic Eng.* **84:** 419–433 (1962)] may be used for these orifices. See also D. B. Collins and M. Gacesa [*J. Basic Eng.* **93:** 11–21 (1971)] for measurements with steam and water beyond the limits of this correlation.

For pressure drop and holdup in *inclined pipe* with upward or downward flow, see Beggs and Brill [*J. Pet. Technol.* **25:** 607–617 (1973)] and R. V. A. Oliemans and B. F. M. Pots [ C. T. Crowe, ed., *Multiphase Flow Handbook*, CRC Press, Boca Raton, Fla., 2006]; the mechanistic model methods referenced above may also be applied to inclined pipes. Up to 10° from horizontal, upward pipe inclination has little effect on holdup [G. A. Gregory, *Can. J. Chem. Eng.* **53:** 384–388 [1975)].

For fully developed incompressible *cocurrent upflow* of gases and liquids in *vertical pipes,* a variety of flow pattern terminologies have appeared in the literature; some of these have been summarized and compared by G. W. Govier et al. [*Can. J. Chem. Eng.* **35:** 58–70 (1957)]. One reasonable classification of patterns is illustrated in Fig. 6-28.

In *bubble flow,* gas is dispersed as bubbles throughout the liquid, with some tendency to concentrate toward the center of the pipe. In *slug flow,* the gas forms large *Taylor bubbles* of diameter nearly equal to the pipe diameter. A thin film of liquid surrounds the Taylor bubble. Between the Taylor bubbles are liquid slugs containing some bubbles. *Froth* or *churn flow* is characterized by strong intermittency and intense mixing, with neither phase easily described as continuous or dispersed. Churn flow may not be a fully developed flow pattern, but instead a large entry length for developing slug flow [L. Zao and A. E. Dukler, *Int. J. Multiphase Flow* **19:** 377–383 (1993); G. F. Hewitt and Jayanti, *Int. J. Multiphase Flow* **19:** 527–529 (1993)].

*Ripple flow* has an upward-moving wavy layer of liquid on the pipe wall; it may be thought of as a transition region to *annular, annular mist,* or *film flow,* in which gas flows in the core of the pipe while an annulus of liquid flows up the pipe wall. Some of the liquid is entrained as droplets in the gas core. *Mist flow* occurs when all the liquid is carried as fine drops in the gas phase; this pattern occurs at high gas velocities, typically 20 to 30 m/s (70 to 100 ft/s).

The correlation by Govier et al. [*Can. J. Chem. Eng.* **35:** 58–70 (1957)], Fig. 6-29, may be used for quick estimate of flow pattern. See R. V. A. Oliemans and B. F. M. Pots [C. T. Crowe, ed., *Multiphase Flow Handbook*, CRC Press, Boca Raton, Fla., 2006] for mechanistic predictions of flow pattern transitions.

*Slip,* or relative velocity between phases, occurs for both vertical and horizontal flow. No completely satisfactory, flow regime–independent correlation for volume fraction or holdup exists for vertical flow. Two frequently

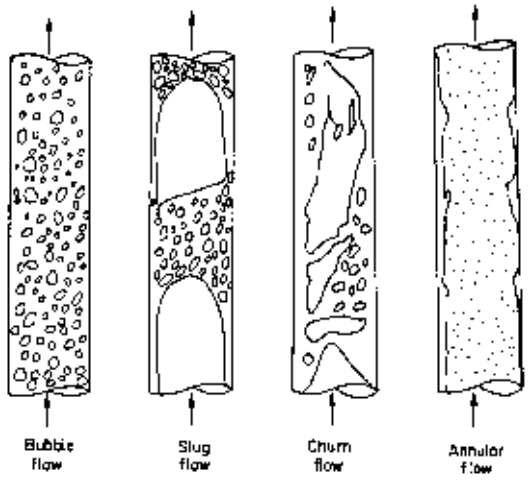

**FIG. 6-28** Flow patterns in cocurrent upward vertical gas/liquid flow. [From Y. Taitel, D. Barnea, and A. E. Dukler, *AIChE J.*, **26,** 345–354 (1980). *Reproduced by permission of the American Institute of Chemical Engineers © 1980 AIChE. All rights reserved.*]

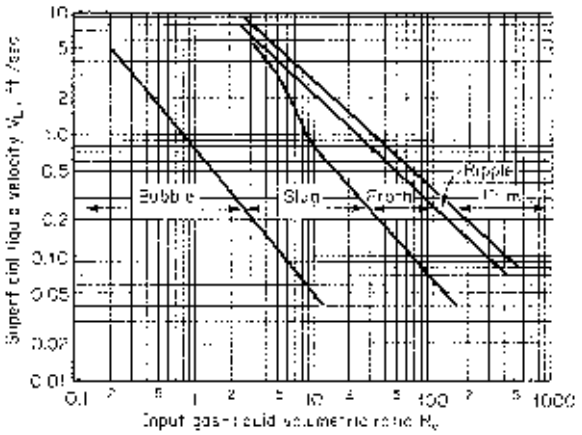

**FIG. 6-29** Flow-pattern regions in cocurrent liquid/gas flow in upflow through vertical pipes. To convert ft/s to m/s, multiply by 0.3048. [From G. W. Govier, B. A. Radford, and J. S. C. Dunn, *Can. J. Chem. Eng.*, **35,** 58–70 (1957).]

used flow regime–independent methods are those by G. A. Hughmark and B. S. Pressburg [*AIChE J.* **7:** 677 (1961)] and G. A. Hughmark [*Chem. Eng. Prog.* **58**(4): 62 (April 1962)]. *Pressure drop* in *upflow* may be calculated by the procedure described in G. A. Hughmark [*Ind. Eng. Chem. Fundam.* **2:** 315–321 (1963)]. The mechanistic, flow regime–based methods are advisable for critical applications.

For *upflow* in *helically coiled tubes,* the flow pattern, pressure drop, and holdup can be predicted by the correlations of S. Banerjee et al. [*Can. J. Chem. Eng.* **47:** 445–453 (1969)] and K. Akagawa et al. [*Bull. JSME* **14:** 564–571 (1971)]. Correlations for flow patterns in *downflow* in vertical pipe are given by T. Oshinowo and M. E. Charles [*Can. J. Chem. Eng.* **52:** 25–35 (1974)] and D. Barnea et al. [*Chem. Eng. Sci.* **37:** 741–744 (1982)]. Use of *drift flux theory* for void fraction modeling in downflow is presented by N. N. Clark and R. L. C. Flemmer [*Chem. Eng. Sci.* **39:** 170–173 (1984)]. *Downward-inclined* two-phase flow data and modeling are given by D. Barnea et al. [*Chem. Eng. Sci.* **37:** 741–744 (1982)]. Data for *downflow* in *helically coiled tubes* are presented by C. Casper [*Chem. Ing. Tech.* **42:** 349–354 (1970)].

The entrance to a *drain* is flush with a horizontal surface, while the entrance to an *overflow* pipe is above the horizontal surface. When such pipes do not run full, considerable amounts of gas can be drawn down by the liquid. The amount of gas entrained is a function of pipe diameter, pipe length, and liquid flow rate as well as the drainpipe outlet boundary condition. Extensive data on air entrainment and liquid head above the entrance as a function of water flow rate for pipe diameters from 43.9 to 148.3 mm (1.7 to 5.8 in) and lengths from about 1.22 to 5.18 m (4.0 to 17.0 ft) are reported by A. A. Kalinske [*Univ. Iowa Stud. Eng. Bull.* **26:** 26–40 (1939–1940)]. For heads greater than the critical, the pipes will run full with no entrainment. The critical head $h$ for flow of water in drains and overflow pipes is given in Fig. 6-30. Kalinske's results show little effect of the height of protrusion of overflow pipes when the protrusion height is greater than about one pipe diameter. For conservative design, N. G. McDuffie [*AIChE J.* **23:** 37–40 (1977)] recommends the following relation for minimum liquid height to prevent entrainment.

$$\mathrm{Fr} \le 1.6\left(\frac{h}{D}\right)^2 \tag{6-140}$$

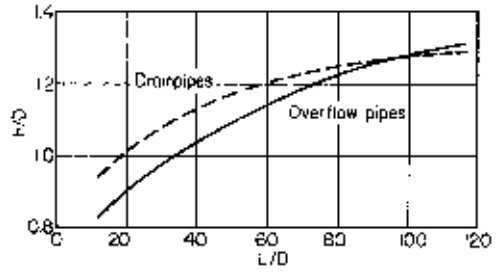

**FIG. 6-30** Critical head for drain and overflow pipes. [From A. A. Kalinske, *Univ. Iowa Stud. Eng., Bull.* **26** (1939–1940).]

where the Froude number is defined by

$$\mathrm{Fr} \equiv \frac{V_L}{\sqrt{g(\rho_L - \rho_G)D/\rho_L}} \tag{6-141}$$

where $g$ = acceleration due to gravity
$V_L$ = liquid velocity in drainpipe
$\rho_L$ = liquid density
$\rho_G$ = gas density
$D$ = pipe inside diameter
$h$ = liquid height

For additional information, see L. L. Simpson [*Chem. Eng.* **75**(6): 192–214 (1968)] and J. N. Tilton and J. A. Garcia [*5th North American Conf. on Multiphase Technology*, Banff, pp. 119–133 (2006)]. A critical Froude number of 0.31 to ensure vented flow is widely cited. Experimental results [R. B.Thorpe, *3d Int. Conf. Multi-phase Flow,* The Hague, Netherlands, May 18–20, 1987, paper K2, and *4th Int. Conf. Multi-phase Flow,* Nice, France, June 19–21, 1989, paper K4] show hysteresis, with different critical Froude numbers for flooding and unflooding of drain pipes, and the influence of end effects. G. B Wallis et al. [*Trans. ASME J. Fluids Eng.* **99:** 405–413 (June 1977)] examine the conditions for horizontal discharge pipes to run full.

*Flashing flow* and *condensing flow* are two examples of multiphase flow with *phase change.* Flashing flow occurs when pressure drops below the bubble point pressure of a flowing liquid. A frequently used one-dimensional model for flashing flow through nozzles and pipes is the *homogeneous equilibrium model,* which assumes that both phases move at the same in situ velocity and maintain vapor/liquid equilibrium. At the *critical,* or *choking flow* condition, the velocity is sonic, evaluated from the derivative of pressure $p$ with respect to mixture density at constant entropy.

$$c = \sqrt{\left(\frac{\partial p}{\partial \rho_m}\right)_s} \tag{6-142}$$

The critical velocity for flashing liquids is normally much less than that for gas flow. The critical mass flux is

$$G_{\mathrm{crit}} = \rho_m \sqrt{\left(\frac{\partial p}{\partial \rho_m}\right)_s} \tag{6-143}$$

The mixture density is given in terms of the individual phase densities and the *quality* (mass flow fraction vapor) $x$ by

$$\frac{1}{\rho_m} = \frac{x}{\rho_G} + \frac{1-x}{\rho_L} \tag{6-144}$$

Choked and unchoked flow situations arise in pipes and nozzles in the same fashion for homogeneous equilibrium flashing flow as for gas flow. For nozzle flow from stagnation pressure $p_0$ to exit pressure $p_1$, the mass flux is given by

$$G^2 = -2\rho_{m1}^2 \int_{p_0}^{p_1} \frac{dp}{\rho_m} \tag{6-145}$$

The integration is carried out over an isentropic flash path: flashes at constant entropy must be carried out to evaluate $\rho_m$ as a function of $p$. Experience shows that isenthalpic flashes provide good approximations unless the liquid mass fraction is very small. Choking occurs when $G$ obtained by Eq. (6-145) goes through a maximum at a value of $p_1$ greater than the external discharge pressure. The maximum flux will match the critical flux from Eq. (6-143). In such a case, the pressure at the nozzle exit equals the choking pressure.

For steady homogeneous flow in a pipe of diameter $D$, the differential form of the Bernoulli equation rearranges to

$$\frac{dp}{\rho_m} + g\,dz + \frac{G^2}{\rho_m} d\frac{1}{\rho_m} + 2f\frac{dx'}{D}\frac{G^2}{\rho_m^2} = 0 \tag{6-146}$$

where $x'$ is distance along the pipe. Integration over a length $L$ of pipe assuming constant friction factor $f$ yields

$$G^2 = \frac{-\int_{p_1}^{p_2} \rho_m\,dp - g\int_{z_1}^{z_2} \rho_m^2\,dz}{\ln(\rho_{m1}/\rho_{m2}) + 2fL/D} \tag{6-147}$$

Frictional pipe flow is not isentropic. Strictly speaking, the flashes must be carried out at constant $h + V^2/2 + gZ$, where $h$ is the enthalpy per unit mass of the two-phase flashing mixture. The effect of potential energy on the flashes

is normally negligible, but the kinetic energy effects are not, for high-quality, high-velocity flows. The flash calculations are fully coupled with the integration of the Bernoulli equation; the velocity $V$ must be known at every pressure $p$ to evaluate $\rho_m$. Computational routines, employing the thermodynamic and material balance features of flow sheet simulators, are the most practical way to carry out such flashing flow calculations, particularly when multicomponent systems are involved. Equation (6-146) may be rearranged to give

$$\frac{dp}{dz} = -\frac{\dfrac{2fG^2}{\rho_m D} + \rho_m g \dfrac{dZ}{dx'}}{1 - \dfrac{G^2}{\rho^2}\dfrac{dp}{d\rho_m}} \tag{6-148}$$

The derivative $dp/d\rho_m$ is carried out at constant $h+V^2/2$. A singularity occurs at critical velocity where $G = G_{crit}$ and the denominator of Eq. (6-148) is zero. At the critical point, the derivative $dp/d\rho_m$ becomes equal to the partial derivative at constant entropy. Significant simplification arises when the mass fraction of liquid is large enough to neglect the effect of the $V^2/2$ term on the flash splits.

With flashes carried out along the appropriate thermodynamic paths, the formalism of Eqs. (6-142) through (6-148) applies to all homogeneous equilibrium compressible flows, including, for example, flashing flow, perfect gas flow, and nonideal gas flow.

Various *nonequilibrium* and *slip flow* models have been proposed as improvements on the homogeneous equilibrium flow model. See, for example, R. E. Henry and H. K. Fauske [*Trans. ASME J. Heat Transfer,* 179–187 (May 1971)]. Nonequilibrium and slip effects both increase computed mass flux for fixed pressure drop, compared to homogeneous equilibrium flow. For flow paths greater than about 100 mm (4 in), homogeneous equilibrium behavior appears to be the best assumption [H. G. Fischer et al., *Emergency Relief System Design Using DIERS Technology,* AIChE, New York, 1992]. For shorter flow paths, a reasonable estimate is to linearly interpolate (as a function of length) between *frozen flow* (constant quality, no flashing) at 0 length and homogeneous equilibrium flow at 100 mm (4 in).

In a series of papers by J. C. Leung and coworkers [*AIChE J.* **32:** 1743–1746 (1986); **33:** 524–527 (1987); **34:** 688–691 (1988); *J. Loss Prevention Proc. Ind.* **2**(2): 78–86 (April 1989); **31:** 27–32 (January 1990); *Trans. ASME J. Heat Transfer* **112:** 524–528, 528–530 (1990); **113:** 269–272 (1991)], approximate techniques have been developed for homogeneous equilibrium calculations based on pseudo–equation of state methods for flashing mixtures. Collectively known as the *omega method,* these developments are discussed in Sec. 23 of this handbook.

Less work has been done on *condensing flows.* Slip effects are more important for condensing than for flashing flows. M. Soliman et al. [*J. Heat Transfer* **90:** 267–276 (1968)] give a model for condensing vapor in *horizontal pipe.* They assume the condensate flows as an annular ring. The Lockhart-Martinelli correlation is used for the frictional pressure drop. To this pressure drop is added an acceleration term based on homogeneous flow, equivalent to $G^2 d(1/\rho_m)$ in Eq. (6-146). Pressure drop is computed by integration of the incremental pressure changes along the length of pipe.

For *condensing vapor* in *vertical downflow,* in which the liquid flows as a thin annular film, the frictional contribution to the pressure drop may be estimated based on the gas flow alone, using the friction factor plotted in Fig. 6-31, where $Re_G$ is the Reynolds number for the gas flowing alone [O. P. Bergelin et al., *Proc. Heat Transfer Fluid Mech. Inst.,* ASME, June 22–24, 1949, pp. 19–28].

$$-\frac{dp}{dz} = \frac{2f'_G \rho_G V_G^2}{D} \tag{6-149}$$

To this should be added the $G_G^2\, d(1/\rho_G)/dx$ term to account for velocity change effects.

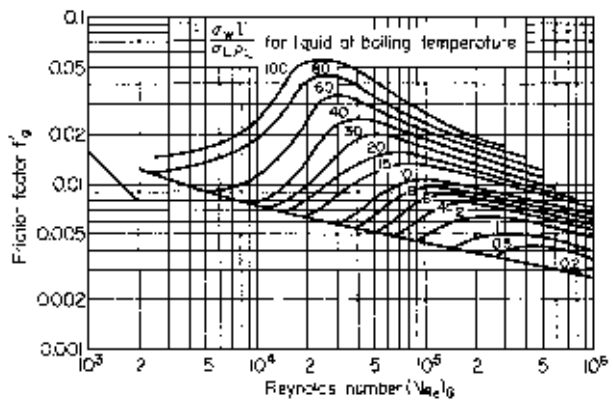

**FIG. 6-31** Friction factors for condensing liquid/gas flow downward in vertical pipe. In this correlation $\Gamma/\rho_L$ is in $ft^2/h$. To convert $ft^2/h$ to $m^2/s$, multiply by 0.00155. [From O. P. Bergelin et al., *Proc. Heat Transfer Fluid Mech. Inst.,* ASME, 1949, p. 19.]

**Gases and Solids** The flow of gases and solids (pneumatic transport) in *horizontal* pipe is usually classified as either *dilute phase* or *dense phase* flow. Unfortunately, there is no clear delineation between the two types of flow, and the *dense phase* description may take on more than one meaning, creating some confusion [T. M. Knowlton et al., *Chem. Eng. Progr.* **90**(4): 44–54 (April 1994)]. S. Dhodapkar et al. in C. T. Crowe [ed., *Multiphase Flow Handbook*, CRC Press, Boca Raton, Fla., 2006] describe pneumatic transport fundamentals and system design. For dilute phase flow, achieved at low solids-to-gas weight ratios (loadings) and high gas velocities, the solids may be fully suspended and fairly uniformly dispersed over the pipe cross section (homogeneous flow), particularly for low-density or small particle size solids. At lower gas velocities, the solids may bounce along the bottom of the pipe. With higher loadings and lower gas velocities, the particles may settle to the bottom of the pipe, forming dunes, with the particles moving from dune to dune. In dense phase conveying, solids tend to concentrate in the lower portion of the pipe at high gas velocity. As the gas velocity decreases, solids may first form dense moving strands, followed by slugs. Discrete plugs of solids may be created intentionally by timed injection of solids, or the plugs may form spontaneously. Eventually the pipe may become blocked. For more information on flow patterns, see J. M. Coulson and J. F. Richardson [*Chemical Engineering,* vol. 2, 2d ed., Pergamon, New York, 1968, p. 583]; C. Y. Wen and H. P. Simons [*AIChE J.* **5:** 263–267 (1959)]; and T. M. Knowlton et al. [*Chem. Eng. Progr.* **90**(4): 44–54 (April 1994)]. For the *minimum velocity* required to prevent formation of dunes or settled beds in *horizontal flow,* data are given by F. A. Zenz [*Ind. Eng. Chem. Fundam.* **3:** 65–75 (1964)], who presented a correlation for the minimum velocity required to keep particles from depositing on the bottom of the pipe. This rather tedious estimation procedure may also be found in G. W. Govier and K. Aziz [*The Flow of Complex Mixtures in Pipes*, Krieger, Huntington, N.Y., 1977], who provide additional references and discussion on transition velocities. In practice, the actual conveying velocities used in systems with loadings less than 10 are generally over 15 m/s (50 ft/s), while for high loadings (>20) they are generally less than 7.5 m/s (25 ft/s) and are roughly twice the actual solids velocity [C. Y. Wen and H. P. Simons [*AIChE J.* **5:** 263–267 (1959)].

Total *pressure drop* for horizontal flow includes acceleration effects at the entrance to the pipe and frictional effects beyond the entrance region. A great number of correlations for pressure gradient are available, none of which is applicable to all flow regimes. G. W. Govier and K. Aziz [*The Flow of Complex Mixtures in Pipes*, Krieger, Huntington, N.Y., 1977] review many of these and provide recommendations on when to use them. S. Dhodapkar et al. in C. T. Crowe [ed., *Multiphase Flow Handbook*, CRC Press, Boca Raton, Fla., 2006] recommend methods for computing pressure drop across the components of a pneumatic system. See also W. C. Yang [*AIChE J.* **24:** 548–552 (1978)].

For *upflow* of gases and solids in *vertical pipes,* the *minimum conveying velocity* for low loadings may be estimated as twice the terminal settling velocity of the largest particles. Equations for terminal settling velocity are found in the Particle Dynamics subsection following. *Choking* occurs as the velocity is dropped below the minimum conveying velocity and the solids are no longer transported, collapsing into solid plugs [T. M. Knowlton et al., *Chem. Eng. Progr.* **90**(4): 44–54 (April 1994)]. See T. N. Smith [*Chem. Eng. Sci.* **33:** 745–749 (1978)] for an equation to predict the onset of choking.

Total *pressure drop* for vertical upflow of gases and solids includes acceleration and frictional effects also found in horizontal flow, plus potential energy or hydrostatic effects. G. W. Govier and K. Aziz [*The Flow of Complex Mixtures in Pipes*, Krieger, Huntington, N.Y., 1977] review many of the pressure drop calculation methods and provide recommendations for their use. See also W. C. Yang [*AIChE J.* **24:** 548–552 (1978)].

*Drag reduction* has been reported for low loadings of small-diameter particles (< 60 μm), ascribed to damping of turbulence near the wall [S. J. Rossetti and R. P. Pfeffer, *AIChE J.* **18:** 31–39 (1972)].

For *dense phase* transport in *vertical pipes* of small diameter, see C. W. Sandy et al. [*Chem. Eng. Prog. Symp. Ser.* **66:** 105, 133–142 (1970)].

The *flow of bulk solids through restrictions and bins* is discussed in symposium articles [*J. Eng. Ind.* **91**(2) (1969)] and by Stepanoff [*Gravity Flow of Bulk Solids and Transportation of Solids in Suspension,* Wiley, New York, 1969]. Some problems encountered in discharge from bins include [T. M. Knowlton et al., *Chem. Eng. Progr.* **90**(4): 44–54 (April 1994)] flow stoppage due to *ratholing* or *arching, segregation* of fine and coarse particles, *flooding* upon collapse of ratholes, and poor *residence time distribution* when *funnel flow* occurs.

**Solids and Liquids** Slurry flow may be divided into two categories based on settling behavior (see A. W. Etchells in P. A. Shamlou [*Processing of Solid-Liquid Suspensions,* chap. 12, Butterworth-Heinemann, Oxford, UK, 1993]. *Nonsettling* slurries are made up of very fine, highly concentrated, or neutrally buoyant particles. These slurries are normally treated as pseudohomogeneous fluids, often quite viscous and usually nonnewtonian. Slurries of particles that tend to settle out rapidly are called *settling slurries* or *fast-settling slurries.* While in some cases positively buoyant solids are encountered, the present discussion will focus on solids which are denser than the liquid.

For *horizontal flow* of *fast-settling slurries,* the following rough description may be made [G. W. Govier and K. Aziz, *The Flow of Complex Mixtures in Pipes*, Krieger, Huntington, N.Y., 1977]. Ultrafine particles, 10 μm or smaller, are generally fully suspended, and the particle distributions are not influenced by gravity. Fine particles 10 to 100 μm are usually fully suspended, but gravity causes concentration gradients. Medium-size particles, 100 to 1000 μm, may be fully suspended at high velocity, but often form a moving deposit on the bottom of the pipe. Coarse particles, 1000 to 10,000 μm, are seldom fully suspended and are usually conveyed as a moving deposit. Ultracoarse particles larger than 10,000 μm are not suspended at normal velocities unless they are unusually light.

Figure 6-32, taken from G. W. Govier and K. Aziz [*The Flow of Complex Mixtures in Pipes*, Krieger, Huntington, N.Y., 1977] schematically indicates four flow pattern regions superimposed on a plot of pressure gradient versus mixture velocity $V_M = V_L + V_S = (Q_L + Q_S)/A$ where $V_L$ and $V_S$ are the superficial liquid and solid velocities, $Q_L$ and $Q_S$ are liquid and solid volumetric flow rates, and $A$ is the pipe cross-sectional area. Also $V_{M4}$ is the transition velocity above which a bed exists in the bottom of the pipe, part of which is stationary and part of which moves by *saltation,* with the upper particles tumbling and bouncing over one another, often with formation of dunes. With a broad particle-size distribution, the finer particles may be fully suspended. Near $V_{M4}$, the pressure gradient rapidly increases as $V_M$ decreases. Above $V_{M3}$, the entire bed moves. Above $V_{M2}$, the solids are fully suspended; that is, there is no deposit, moving or stationary, on the bottom of the pipe. However, the concentration distribution of solids is asymmetric. This flow pattern is the most frequently used for fast-settling slurry transport. Typical mixture velocities are in the range of 1 to 4 m/s (3 to 13 ft/s). The minimum in the pressure gradient is found to be near $V_{M2}$. Above $V_{M1}$, the particles are symmetrically distributed, and the pressure gradient curve is nearly parallel to that for the liquid by itself.

The most important transition velocity, often regarded as the minimum transport or conveying velocity for settling slurries, is $V_{M2}$. The Durand equation [R. Durand, Minnesota Int. Hydraulics Conf., *Proc.,* 89, Int. Assoc. for Hydraulic Research (1953); R. Durand and E. Condolios, *Proc. Colloq. on the Hyd. Transport of Solids in Pipes, Nat. Coal Board* [*UK*], Paper IV, 39–35 (1952)] gives the minimum transport velocity as

$$V_{M2} = F_L[2gD(s-1)]^{0.5} \tag{6-150}$$

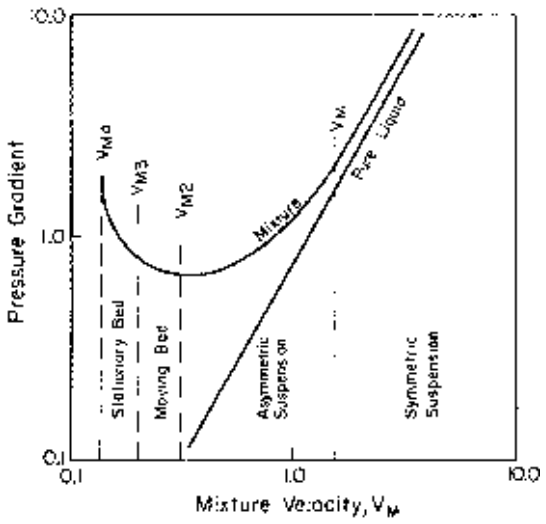

**FIG. 6-32** Flow pattern regimes and pressure gradients in horizontal slurry flow. (From G. W. Govier and K. Aziz, *The Flow of Complex Mixtures in Pipes*, Van Nostrand Reinhold, New York, 1972.]

where $g$ = acceleration of gravity
$D$ = pipe diameter
$s = \rho_S/\rho_L$ = ratio of solid to liquid density
$F_L$ = a factor influenced by particle size and concentration

Figure 6-33 gives Durand's empirical correlation for $F_L$ as a function of particle diameter and the input, feed volume fraction solids, $C_S = Q_S/(Q_S + Q_L)$. Common practice for conservative design is to use $F_L = 1.5$. R. M. Turian et al. [*Powder Technol.* **51:** 35–47 (1987)] regressed an extensive data set using up to five parameters. The five-parameter result is shown below, but inclusion of all five parameters did not show significant improvement in RMS error.

$$F_L = 1.7951 C_S^{0.1087}(1-C_S)^{0.2501}\left\{\frac{D\rho_L[gD(s-1)]^{0.5}}{\mu}\right\}^{0.00179}\left(\frac{d}{D}\right)^{0.06623} \tag{6-151}$$

See A. P. Poloski et al. [*Can. J. Chem. Engr.* **88:** 182–189 (2010)] for data regressions focusing on small-particle (Archimedes number less than 80) transport.

No single correlation for *pressure drop* in horizontal solid/liquid flow has been found satisfactory for all particle sizes, densities, concentrations, and pipe sizes. However, with reference to Fig. 6-32, the following simplifications may be considered. The minimum pressure gradient occurs near $V_{M2}$, and for conservative purposes it is generally desirable to exceed $V_{M2}$. When $V_{M2}$ is exceeded, a rough guide for pressure drop is 25 percent greater than that calculated assuming that the slurry behaves as a pseudohomogeneous fluid with the density of the mixture and the viscosity of the liquid. Above the transition velocity to symmetric suspension, $V_{M1}$, the pressure drop closely approaches the pseudohomogeneous pressure drop.

The following correlation by K. E. Spells [*Trans. Inst. Chem. Eng.* (*London*), **33:** 79–84 (1955)] may be used for $V_{M1}$.

$$V_{M1}^2 = 0.075\left(\frac{DV_{M1}\rho_M}{\mu}\right)^{0.775} gD_S(s-1) \tag{6-152}$$

where $D$ = pipe diameter
$D_S$ = particle diameter (such that 85 percent by weight of particles are smaller than $D_S$)
$\rho_M$ = slurry mixture density
$\mu$ = liquid viscosity
$s = \rho_S/\rho_L$ = ratio of solid to liquid density

Between $V_{M2}$ and $V_{M1}$ the concentration of solids gradually becomes more uniform. This transition has been modeled by several authors as a concentration gradient where turbulent diffusion balances gravitational settling. See, for example, A. J. Karabelas [*AIChE J.* **23:** 426–434 (1977)].

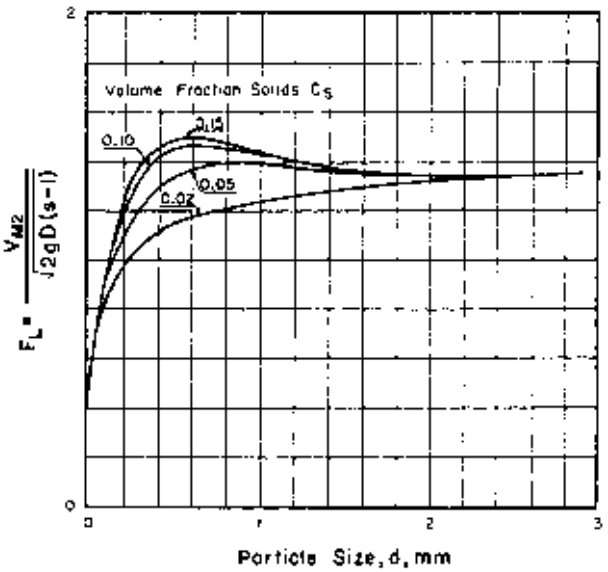

**FIG. 6-33** Durand factor for minimum suspension velocity. [From G. W. Govier and K. Aziz, *The Flow of Complex Mixtures in Pipes*, Van Nostrand Reinhold, New York, 1972.]

Published correlations for pressure drop are frequently very complicated and tedious to use and may not offer significant accuracy advantages over the simple guide given here, and many of them are applicable only for velocities above $V_{M2}$. One that does include the effect of sliding beds is due to H. Gaessler [Doctoral Dissertation, Technische Hochshule, Karlsruhe, Germany, 1967] and reproduced by G. W. Govier and K. Aziz [*The Flow of Complex Mixtures in Pipes*, Krieger, Huntington, N.Y., 1977, pp. 668–669]. R. M. Turian and Yuan [*AIChE J.* **23:** 232–243 (1977); see also R. M. Turian and T. F. Yuan [*AIChE J.* **23:** 232–243 (1977)] segregated a large body of data into four flow regime groups and developed empirical correlations for predicting pressure drop in each flow regime.

The flow behavior of fiber suspensions is discussed by Bobkowicz and Gauvin [*Chem. Eng. Sci.* **22:** 229–241 (1967)], Bugliarello and Daily [*TAPPI,* **44:** 881–893 (1961)], and Daily and Bugliarello [*TAPPI* **44:** 497–512 (1961)].

In *vertical flow* of fast-settling slurries, the in situ concentration of solids with density greater than the liquid will exceed the feed concentration $C_S = Q_S/(Q_S + Q_L)$ for upflow and will be smaller than $C_S$ for downflow. This results from slip between the phases. The *slip velocity,* the difference between the in situ average velocities of the two phases, is roughly equal to the terminal settling velocity of the solids in the liquid. Specification of the slip velocity for a pipe of a given diameter, along with the phase flow rates, allows calculation of in situ volume fractions, average velocities, and holdup ratios by simple material balances. Slip velocity may be affected by particle concentration and by turbulence conditions in the liquid. *Drift-flux theory,* a framework incorporating certain functional forms for empirical expressions for slip velocity, is described by G. B. Wallis [*One-Dimensional Two-Phase Flow,* McGraw-Hill, New York, 1969]. The correlation of J. F. Richardson and W. N. Zaki [*Trans. Instn. Chem. Engrs.* **32:** 35–53 (1954)] for sedimentation velocity may be expressed in drift-flux form

$$j_{LS} = v_\infty \varepsilon^n (1-\varepsilon) \tag{6-153}$$

where the drift velocity $j_{LS}$ is the average in situ velocity of the liquid relative to the mixture velocity and $v_\infty$ is the terminal settling velocity of a single particle. The slip velocity, $v_{LS} = v_L - v_S = (V_L/\varepsilon) - (V_S/[1-\varepsilon])$, the difference between the in situ velocities, is

$$v_{LS} = v_\infty \varepsilon^{n-1} \tag{6-154}$$

where $V_L$ and $V_S$ are the superficial velocities. The exponent $n$ is a function of particle Reynolds number $\mathrm{Re} = dv_\infty \rho / \mu$ and the particle-to-pipe diameter ratio $d/D$.

$$\begin{aligned}
&\mathrm{Re} < 0.2 && n = 4.65 + 19.5\frac{d}{D} \\
&0.2 < \mathrm{Re} < 1 && n = \left(4.35 + 17.5\frac{d}{D}\right)\mathrm{Re}^{-0.03} \\
&1 < \mathrm{Re} < 200 && n = \left(4.45 + 18\frac{d}{D}\right)\mathrm{Re}^{-0.1} \\
&200 < \mathrm{Re} < 500 && n = 4.45\,\mathrm{Re}^{-0.1} \\
&\mathrm{Re} > 500 && n = 2.39
\end{aligned} \tag{6-155}$$

*Minimum transport velocity* for upflow for design purposes is usually taken as twice the particle settling velocity. *Pressure drop* in vertical pipe flow includes the effects of kinetic and potential energy (elevation) changes and friction. H. E. Rose and R. A. Duckworth [*The Engineer* **227**(5903): 392 (1969); **227**(5904): 430 (1969); **227**(5905): 478 (1969)]; see also G. W. Govier and K. Aziz [*The Flow of Complex Mixtures in Pipes*, Krieger, Huntington, N.Y., 1977, pp. 487–493] have developed a calculation procedure including all these effects, which may be applied not only to vertical solid/liquid flow, but also to gas/solid flow and to horizontal flow.

For fast-settling slurries, ensuring conveyance is usually the key design issue while pressure drop is somewhat less important. For *nonsettling slurries* conveyance is not an issue, because the particles do not separate from the liquid. Here, rheological behavior, which controls pressure drop, takes on critical importance. Further discussion of both fast-settling and nonsettling slurries may be found in C. A. Shook [in P. A. Shamlou, *Processing of Solid-Liquid Suspensions,* chap. 11, Butterworth-Heinemann, Oxford, UK, 1993].

## FLUID DISTRIBUTION

Uniform fluid distribution is essential for efficient operation of many types of chemical-processing equipment. To obtain satisfactory distribution, proper consideration must be given to flow behavior in the distributor, flow conditions upstream and downstream of the distributor, and the distribution requirements of the equipment. This subsection provides guidelines for the design of various types of fluid distributors.

**FIG. 6-34** Perforated-pipe distributor.

**Perforated-Pipe Distributors** The perforated pipe or sparger (Fig. 6-34) is a common type of distributor. As shown, the flow distribution is uniform; this is the case when the pressure drop across the holes is large compared to the pressure variation in the pipe due to velocity change and friction. Elevation changes may be also important when liquids are discharged into gases and vice versa. Sometimes hole size or spacing is varied to compensate for pressure variation along the pipe. In typical turbulent flow applications, in relatively short distributor pipes, inertial effects associated with velocity changes may exceed or even dominate frictional losses in determining the pressure distribution along the pipe. Application of the momentum or mechanical energy equations in such a case shows that the pressure inside the pipe increases with distance from the entrance. If the outlet holes are uniform in size and spacing, the discharge flow will be biased toward the closed end. Disturbances upstream of the distributor, such as pipe bends, may increase or decrease the flow to the holes at the beginning of the distributor. When frictional pressure drop dominates the inertial pressure recovery, the distribution is biased toward the feed end of the distributor.

For turbulent flow in a horizontal pipe distributor, with roughly uniform distribution, assuming a constant friction factor, the combined effect of friction and inertial (momentum) pressure recovery is given by

$$\Delta p = \left(\frac{4fL}{3D} - 2K\right)\frac{\rho V_i^2}{2} \qquad \text{(discharge manifolds)} \tag{6-156}$$

where $\Delta p$ = net pressure drop over length of distributor
$L$ = pipe length
$D$ = pipe diameter
$f$ = Fanning friction factor
$V_i$ = distributor inlet velocity

The factor $K$ would be 1 in the case of full momentum recovery, or 0.5 in the case of negligible viscous losses in the portion of flow that remains in the pipe after the flow divides at a takeoff point [M. M. Denn, *Process Fluid Mechanics,* Prentice-Hall, Englewood Cliffs, N.J., 1979]. Experimental data [B. G. Van der Hegge Zijnen, *Appl. Sci. Res.* **A3:** 144–162 (1951–1953)]; and B. J. Bailey [*J. Mech. Eng. Sci.* **17:** 338–347 (1975)], while scattered, show that $K$ is probably close to 0.5 for discharge manifolds. For inertially dominated flows, $\Delta p$ will be negative. For *return manifolds,* the recovery factor $K$ is close to 1.0, and the pressure drop between the first hole and the exit is given by

$$\Delta p = \left(\frac{4fL}{3D} + 2K\right)\frac{\rho V_e^2}{2} \qquad \text{(return manifolds)} \tag{6-157}$$

where $V_e$ is the pipe exit velocity.

One means to obtain a desired uniform distribution is to make the average pressure drop across the holes $\Delta p_o$ large compared to the pressure variation over the length of pipe $\Delta p$. Then the relative variation in pressure drop across the holes will be small, and so will be the variation in flow. When the area of an individual hole is small compared to the cross-sectional area of the pipe, hole pressure drop may be expressed in terms of the discharge coefficient $C_o$ and the velocity across the hole $V_o$ as

$$\Delta p_o = \frac{1}{C_o^2}\frac{\rho V_o^2}{2} \tag{6-158}$$

Provided $C_o$ is the same for all the holes, the *percent maldistribution,* defined as the percentage variation in flow between the first and last holes, may be estimated reasonably well for small maldistribution by [V. E. Senecal, *Ind. Eng. Chem.* **49:** 993–997 (1957)]

$$\%\ \text{maldistribution} = 100\left(1 - \sqrt{\frac{\Delta p_o - |\Delta p|}{\Delta p_o}}\right) \tag{6-159}$$

This equation shows that for 5 percent maldistribution, the pressure drop across the holes should be about 10 times the pressure variation over the length of the pipe. For discharge manifolds with $K = 0.5$ in Eq. (6-156), and with $4fL/3D \ll 1$,

the pressure drop across the holes should be 10 times the inlet velocity head, $\rho V_i^2/2$ for 5 percent maldistribution. This leads to a simple design equation.

Discharge manifolds, $4fL/3D \ll 1$, 5% maldistribution:

$$\frac{V_o}{V_i} = \frac{A_p}{A_o} = \sqrt{10}C_o \tag{6-160}$$

Here $A_p$ = pipe cross-sectional area and $A_o$ is the *total* hole area of the distributor. Use of large ratios of hole velocity to pipe velocity promotes perpendicular discharge streams. In practice, there are many cases where the $4fL/3D$ term will be less than unity but not close to zero. In such cases, Eq. (6-160) will be conservative, while Eqs. (6-156), (6-158), and (6-159) will give more accurate design calculations. In cases where $4fL/(3D) > 2$, friction effects are large enough to render Eq. (6-160) nonconservative. When significant variations in $f$ along the length of the distributor occur, calculations should be made by dividing the distributor into small enough sections that constant $f$ may be assumed over each section.

For return manifolds with $K = 1.0$ and $4fL/(3D) \ll 1$, 5 percent maldistribution is achieved when the hole pressure drop is 20 times the pipe exit velocity head.

Return manifolds, $4fL/3D \ll 1$, 5% maldistribution:

$$\frac{V_o}{V_e} = \frac{A_p}{A_o} = \sqrt{20}C_o \tag{6-161}$$

When $4fL/3D$ is not negligible, Eq. (6-161) is not conservative and Eqs. (6-157), (6-158), and (6-159) should be used.

A common misconception is that good distribution is always provided by high pressure drop, so that increasing flow rate improves distribution by increasing the pressure drop. Conversely, it is mistakenly believed that turndown of flow through a perforated pipe will cause maldistribution. However, when both the pipe flow and the orifice flow are inertially dominated, changing the flow rate changes $\Delta p$ and $\Delta p_o$ in the same proportion, and the distribution uniformity is unchanged. Similarly, when pipe flow and orifice flow are both viscous-dominated, the flow rate has no effect on distribution.

Sometimes design for uniform velocity through uniformly sized and spaced orifices is impractical, because either the pressure drop required for an acceptable pipe diameter is too large, or the pipe diameter required for an acceptable pressure drop is too large. Some measures for such a situation include the following:

1. Taper the diameter of the distributor pipe so that the pipe velocity and velocity head remain constant along the pipe, thus substantially reducing inertial pressure variation.
2. Vary the hole size and/or the spacing between holes to compensate for the pressure variation along the pipe.
3. Feed or withdraw from both ends, reducing the pipe flow velocity head and required hole pressure drop by a factor of 4.

The orifice discharge coefficient $C_o$ is usually taken to be about 0.62. However, $C_o$ is dependent on the ratios of hole diameter to pipe diameter, pipe wall thickness to hole diameter, and pipe velocity to hole velocity. As long as all these are small, and the orifice Reynolds number is greater than about 100, the coefficient 0.62 is generally adequate.

***Example 6-9 Pipe Distributor*** A 3-in Schedule 40 (inside diameter 7.793-cm) pipe is to be used as a distributor for a flow of 0.010 $m^3/s$ of water ($\rho$ = 1000 $kg/m^3$, $\mu$ = 0.001 Pa · s). The pipe is 0.7 m long and is to have 10 holes of uniform diameter and spacing along the length of the pipe. The distributor pipe is submerged. Calculate the required hole size to limit maldistribution to 5 percent, and estimate the pressure drop across the distributor.

The inlet velocity $V_i = Q/A_p = 4Q/(\pi D^2) = 2.10$ m/s, and the inlet Reynolds number is

$$\mathrm{Re} = \frac{DV_i\rho}{\mu} = \frac{0.07793 \times 2.10 \times 1000}{0.001} = 1.64 \times 10^5$$

For commercial pipe with roughness $\varepsilon = 0.046$ mm, the friction factor is about 0.0043. Approaching the last hole, the flow rate, velocity, and Reynolds number are about one-tenth of their inlet values. At Re = 16,400 the friction factor $f$ is about 0.0070. Using an average value of $f = 0.0057$ over the length of the pipe, $4fL/3D$ is 0.068 and may reasonably be neglected so that Eq. (6-158) may be used. With $C_o = 0.62$,

$$\frac{V_o}{V_i} = \frac{A_p}{A_o} = \sqrt{10}C_o = \sqrt{10} \times 0.62 = 1.96$$

With pipe cross-sectional area $A_p = 0.00477$ $m^2$, the total hole area is 0.00477/1.96 = 0.00243 $m^2$. The area and diameter of each hole are then 0.00243/10 = 0.000243 $m^2$ and 1.76 cm, respectively. With $V_o/V_i = 1.96$, the hole velocity is 1.96 × 2.10 = 4.12 m/s, and the pressure drop across the holes is obtained from Eq. (6-158).

$$\Delta p_o = \frac{1}{C_o^2}\frac{\rho V_o^2}{2} = \frac{1}{0.62^2} \times \frac{1000(4.12)^2}{2} = 22{,}100 \text{ Pa}$$

The hole pressure drop is 10 times the pressure variation in the pipe; the total pressure drop from the inlet of the distributor may be taken as approximately 22,100 Pa.

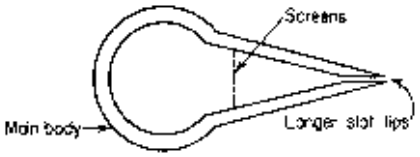

**FIG. 6-35** Modified slot distributor.

Further detailed information on pipe distributors may be found in V. E. Senecal [*Ind. Eng. Chem.* **49:** 993–997 (1957)]. Much of the information on tapered manifold design has appeared in the pulp and paper literature [A. C. Spengos and R. B. Kaiser, *TAPPI* **46**(3): 195–200 (1963); G. D. Madeley, *Paper Technology* **9**(1): 35–39 (1968); J. Mardon et al., *TAPPI* **46**(3): 172–187 (1963); J. Mardon et al., *Pulp and Paper Magazine of Canada* **72**(11): 76–81 (November 1971); A. D. Trufitt, *TAPPI* **5**(11): 144–145 (1975)].

**Slot Distributors** These devices are generally used in sheeting dies for extrusion of films and coatings and in air knives for control of thickness of a material applied to a moving sheet. A simple slotted pipe for turbulent flow conditions may give severe maldistribution because of nonuniform discharge velocity, but also because this type of design does not readily give perpendicular discharge [A. Koestel and G. L. Tuve, *Heat. Piping Air Cond.* **20**(1): 153–157 (1948); V. E. Senecal, *Ind. Eng. Chem.* **49:** 993–997 (1957); A. Koestel and C. Y. Young, *Heat Piping Air Cond.* **23**(7): 111–115 (1951)]. For slots in tapered ducts where the duct cross-sectional area decreases linearly to zero at the far end, the discharge angle will be constant along the length of the duct (Koestel and Young). If the slot area is less than one-tenth of the pipe cross-sectional area, discharge will be perpendicular. As in the case of perforated-pipe distributors, pressure variation within the slot manifold and pressure drop across the slot must be carefully considered. In practice, the following methods may be used to keep the diameter of the pipe to a minimum consistent with good performance [V. E. Senecal, *Ind. Eng. Chem.* **49:** 993–997 (1957)].

1. Feed from both ends.
2. Modify the cross-sectional design (Fig. 6-35); the slot is thus farther away from the influence of feed stream velocity.
3. Increase pressure drop across the slot; this can be accomplished by lengthening the lips (Fig. 6-35).
4. Use screens (Fig. 6-35) to increase overall pressure drop across the slot.

Design of air knives is discussed by V. E. Senecal [*Ind. Eng. Chem.* **49:** 993–997 (1957)]. Design procedures for extrusion dies are presented by E. C. Bernhardt [*Processing of Thermoplastic Materials,* Rheinhold, New York, 1959, pp. 248–281].

**Turning Vanes** In applications such as ventilation, the discharge profile from slots can be improved by turning vanes. The tapered duct is the most amenable for turning vanes because the discharge angle remains constant. One way of installing the vanes is shown in Fig. 6-36. The vanes should have a depth twice the spacing [*Heating, Ventilating, Air Conditioning Guide,* vol. 38, American Society of Heating, Refrigerating and Air-Conditioning Engineers, 1960, pp. 282–283] and a curvature at the upstream end of the vanes of a circular arc which is tangent to the discharge angle $\theta$ of a slot without vanes and perpendicular at the downstream or discharge end of the vanes [A. Koestel and C. Y. Young, *Heat Piping Air Cond.* **23**(7): 111–115 (1951)]. The angle $\theta$ can be estimated from

$$\cot\theta = \frac{C_d A_s}{A_d} \tag{6-162}$$

where $A_s$ = slot area
$A_d$ = duct cross-sectional area at upstream end
$C_d$ = discharge coefficient of slot

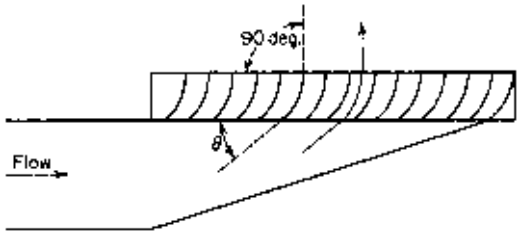

**FIG. 6-36** Turning vanes in a slot distributor.

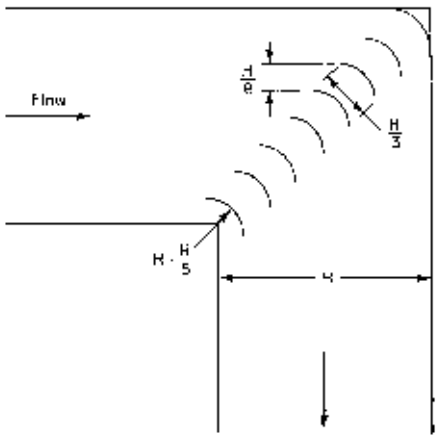

**FIG. 6-37** Miter bend with vanes.

Vanes may be used to improve velocity distribution and reduce frictional loss in bends, when the ratio of bend turning radius to pipe diameter is less than 1.0. For a miter bend with low-velocity flows, simple circular arcs (Fig. 6-37) can be used, and with high-velocity flows, vanes of special airfoil shapes are required. For additional details and references, see E. Ower and R. C. Pankhurst [*The Measurement of Air Flow,* Pergamon, New York, 1977, p. 102]; R. C. Pankhurst and D. W. Holder [*Wind-Tunnel Technique,* Pitman, London, 1952, pp. 92–93]; H. Rouse [*Engineering Hydraulics,* Wiley, New York, 1950, pp. 399–401]; and R. Jorgensen [*Fan Engineering,* 7th ed., Buffalo Forge Co., Buffalo, N.Y., 1970, pp. 111, 117, 118].

**Perforated Plates and Screens** A nonuniform velocity profile in turbulent flow through channels or process equipment can be smoothed out to any desired degree by adding sufficient uniform resistance, such as perforated plates or screens across the flow channel, as shown in Fig. 6-38. R. L. Stoker [*Ind. Eng. Chem.* **38:** 622–624 (1946)] provides the following equation for the effect of a uniform resistance on velocity profile:

$$\frac{V_{2,\max}}{V} = \sqrt{\frac{(V_{1,\max}/V)^2 + \alpha_2 - \alpha_1 + \alpha_2 K}{1+K}} \tag{6-163}$$

Here, $V$ is the area average velocity, $K$ is the number of velocity heads of pressure drop provided by the uniform resistance, $\Delta p = K\rho V^2/2$, and $\alpha$ is the velocity profile factor used in the mechanical energy balance, Eq. (6-18). It is the ratio of the area average of the cube of the velocity, to the cube of the area average velocity $V$. The shape of the exit velocity profile appears twice in Eq. (6-163), in $V_{2,\max}/V$ and $\alpha_2$. Typically, $K$ is on the order of 10, and the desired exit velocity profile is fairly uniform so that $\alpha_2 \sim 1.0$ may be appropriate. Downstream of the resistance, the velocity profile will gradually reestablish the fully developed profile characteristic of the Reynolds number and channel shape.

Screens and other flow restrictions may also be used to suppress stream swirl and turbulence [R. I. Loehrke and H. M. Nagib, *J. Fluids Eng.* **98:** 342–353 (1976)]. Contraction of the channel, as in a venturi, provides further reduction in turbulence level and flow nonuniformity.

**Beds of Solids** A suitable depth of solids can be used as a fluid distributor. A pressure drop of 10 velocity heads is typically used, here based on the superficial velocity through the bed. There are several substantial disadvantages to use of particle beds for flow distribution. Heterogeneity of the bed may actually worsen rather than improve distribution. Uniform flow may be found only downstream of the point in the bed where sufficient pressure drop has occurred to produce uniform flow. Therefore, inefficiency results when the bed also serves reaction or mass transfer functions, since portions of the bed are bypassed. In the case of trickle flow of liquid downward through column packings, inlet distribution is critical since the bed itself is relatively ineffective in distributing the liquid. Maldistribution of flow through packed beds also arises when the ratio of bed diameter to particle size is less than 10 to 30.

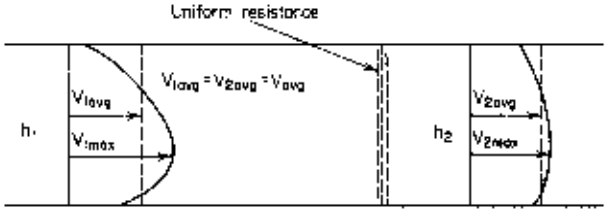

**FIG. 6-38** Smoothing out a nonuniform profile in a channel.

**Other Flow-Straightening Devices** Other devices designed to produce uniform velocity or reduce swirl, sometimes with reduced pressure drop, are available. These include both commercial devices of proprietary design and devices discussed in the literature. For pipeline flows, see the references under flow inverters and static mixing elements previously discussed in the Incompressible Flow in Pipes and Channels subsection. For large area changes, such as at the entrance to a vessel, it is sometimes necessary to diffuse the momentum of the inlet jet discharging from the feed pipe in order to produce a more uniform velocity profile within the vessel. Methods for this application exist, but are often proprietary.

## FLUID MIXING

Mixing of fluids is a discipline of fluid mechanics. Fluid motion is used to accelerate the otherwise slow processes of diffusion and conduction to bring about uniformity of concentration and temperature, blend materials, facilitate chemical reactions, bring about intimate contact of multiple phases, and so on. A brief introduction and some references for further information are given here. E. L. Paul et al. [*Handbook of Industrial Mixing*, Wiley-Interscience, Hoboken, N.J., 2004], updated in S. M. Kresta et al. [*Advances in Industrial Mixing*, Wiley, Hoboken, N.J., 2016], is the most comprehensive and up-to-date reference. Textbooks include N. Harnby et al. [*Mixing in the Process Industries,* 2d ed., Butterworths, London, 1992]; J. Y. Oldshue [*Fluid Mixing Technology,* McGraw-Hill, New York, 1983]; G. B. Tatterson [*Fluid Mixing and Gas Dispersion in Agitated Tanks,* McGraw-Hill, New York, 1991]; V. W. Uhl and J. B. Gray [*Mixing,* vols. 1–3, Academic, New York, 1966, 1967, 1986]; and S. Nagata [*Mixing: Principles and Applications,* Wiley, New York, 1975]. A good, though dated, overview of stirred tank agitation is given in the series of articles from *Chemical Engineering* [pp. 110–114, Dec. 8, 1975; pp. 139–145, Jan. 5, 1976; pp. 93–100, Feb. 2, 1976; pp. 102–110, Apr. 26, 1976; pp. 144–150, May 24, 1976; pp. 141–148, July 19, 1976; pp. 89–94, Aug. 2, 1976; pp. 101–108, Aug. 30, 1976; pp. 109–112, Sept. 27, 1976; pp. 119–126, Oct. 25, 1976; pp. 127–133, Nov. 8, 1976].

Process mixing is commonly carried out in pipelines and vessels. The terms *radial mixing* and *axial mixing* are commonly used. Axial mixing refers to mixing of materials that pass a given point at different times and thus leads to *back-mixing.* For example, back-mixing or axial mixing occurs in stirred tanks where fluid elements entering the tank at different times are intermingled. Mixing of elements initially at different axial positions in a pipeline is axial mixing. Radial mixing occurs between fluid elements passing a given point at the same time, such as between fluids mixing in a pipeline tee.

*Turbulent flow,* by means of the chaotic eddy motion associated with velocity fluctuation, is conducive to rapid mixing and therefore is the preferred flow regime for mixing. *Laminar mixing* is carried out when high viscosity makes turbulent flow impractical.

**Stirred Tank Agitation** Turbine impeller agitators, of a variety of shapes, are used for stirred tanks, predominantly in turbulent flow. Figure 6-39 shows typical stirred tank configurations and time-averaged flow patterns for axial flow and radial flow impellers. In order to prevent formation of a *vortex,* four vertical baffles are normally installed. These cause top-to-bottom mixing and prevent mixing-ineffective swirling motion.

For a given impeller and tank geometry, the impeller Reynolds number determines the flow pattern in the tank:

$$\mathrm{Re}_I = \frac{D^2 N \rho}{\mu} \tag{6-164}$$

where $D$ = impeller diameter, $N$ = rotational speed, and $\rho$ and $\mu$ are the liquid density and viscosity, respectively. Rotational speed $N$ is typically reported in revolutions per minute, or revolutions per second in SI units. Radians per second are almost never used. Typically, $\mathrm{Re}_I > 10^4$ is required for fully turbulent conditions throughout the tank. A wide transition region between laminar and turbulent flow occurs over the range $10 < \mathrm{Re}_I < 10^4$.

The power $P$ drawn by the impeller is made dimensionless in a group called the *power number*:

$$\mathrm{N}_P = \frac{P}{\rho N^3 D^5} \tag{6-165}$$

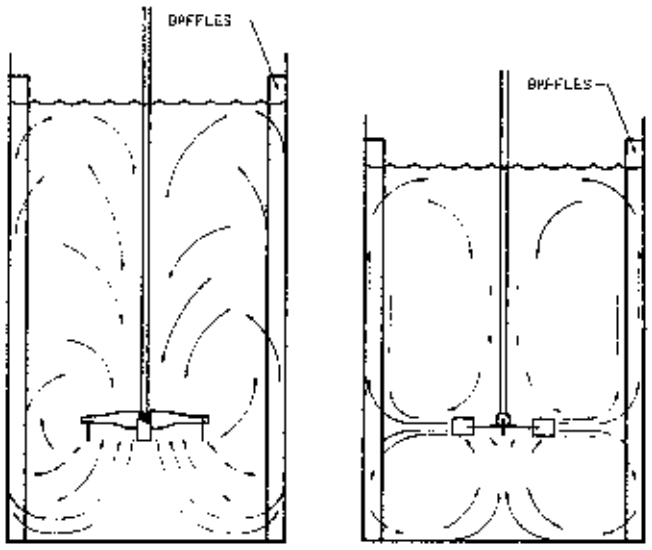

**FIG. 6-39** Typical stirred tank configurations, showing time-averaged flow patterns for axial flow and radial flow impellers. [From J. Y. Oldshue, *Fluid Mixing Technology*, McGraw-Hill, New York, 1983.]

Figure 6-40 shows power number versus impeller Reynolds number for several impeller types. The similarity to the friction factor versus Reynolds number behavior for pipe flow is significant. In laminar flow, the power number is inversely proportional to the Reynolds number, reflecting the dominance of viscous forces over inertial forces. In turbulent flow, where inertial forces dominate, the power number is nearly constant.

The total volumetric flow rate $Q$ discharged by an impeller is made dimensionless in a pumping number:

$$N_Q = \frac{Q}{ND^3} \tag{6-166}$$

Blend time $t_b$, the time required to achieve a specified standard deviation of concentration after injection of a tracer into a stirred tank, is made dimensionless by multiplying by the impeller rotational speed:

$$N_b = t_b N \tag{6-167}$$

Dimensionless pumping number and blend time are independent of Reynolds number under fully turbulent conditions. The magnitude of concentration fluctuations from the final well-mixed value in batch mixing decays exponentially with time.

The design of mixing equipment depends on the desired process result. There is often a tradeoff between operating cost, which depends mainly on power, and capital cost, which depends on agitator size and torque. For some applications bulk flow throughout the vessel is desired, while for others high local turbulence intensity is required. Multiphase systems introduce such design criteria as solids suspension and gas dispersion. In very viscous systems, helical ribbons, extruders, and other specialized equipment types are favored over turbine agitators.

**Pipeline Mixing** Mixing may be carried out with *mixing tees, inline* or *motionless mixing elements*, or in empty pipe. In the latter case, large pipe lengths may be required to obtain adequate mixing. Coaxially injected streams require lengths on the order of 100 pipe diameters.

Properly designed tee mixers, with due consideration given to mainstream and injected stream momentum, are capable of producing high degrees of uniformity in just a few diameters. L. J. Forney ["Jet Injection for Optimum Pipeline Mixing," in *Encyclopedia of Fluid Mechanics*, vol. 2., chap. 25, Gulf Publishing, Houston, Tex., 1986] provides a thorough discussion of tee mixing. Inline or motionless mixers are generally of proprietary commercial design, and they may be selected for viscous or turbulent, single-phase or multiphase mixing applications. They substantially reduce

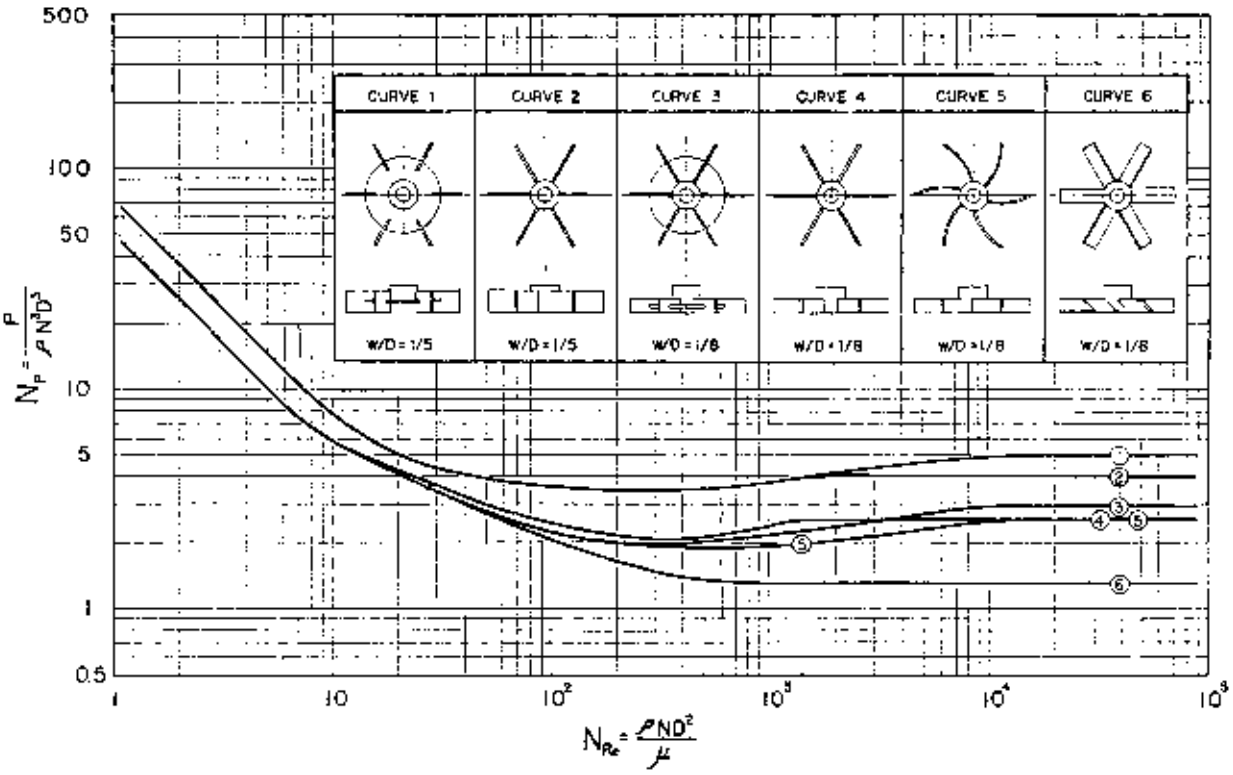

**FIG. 6-40** Dimensionless power number in stirred tanks. [Reprinted with permission from R. L. Bates, P. L. Fondy, and R. R. Corpstein, *Ind. Eng. Chem. Process Design Develop.*, **2,** 310 (1963).]

required pipe length for mixing. See E. L. Paul et al. [*Handbook of Industrial Mixing*, Wiley-Interscience, Hoboken, N.J., 2004] for further information on static mixers.

## TUBE BANKS

Pressure drop across tube banks may not be correlated by means of a single, simple friction factor—Reynolds number curve, owing to the variety of tube configurations and spacings encountered. The most common are staggered and in-line arrays, as shown in Fig. 6-41. Several investigators have allowed for configuration and spacing by incorporating spacing factors in their friction factor expressions or by using multiple friction factor plots. Heat exchanger design is the most important application for evaluating pressure drop for flow across tube banks. Commercial computer codes for heat-exchanger design are available which include features for estimating pressure drop across tube banks. These calculations are complicated by the fact that flow is not strictly normal to the tubes, even within each tube pass, as well as by the need to estimate turning losses in flow around baffles.

For flow normal to tube banks, the pressure drop is generally expressed in terms of the number of velocity heads lost, based on the maximum velocity, evaluated at the minimum free flow cross-sectional area.

$$\Delta p = K\frac{\rho V_{\max}^2}{2} \tag{6-168}$$

The head loss factor becomes proportional to the number of tube rows when the number of rows is large. G. F. Hewitt et al. [*Process Heat Transfer,* CRC Press, Boca Raton, Fla., 1994] use

$$K = K_a + n_r K_r \tag{6-169}$$

where $K_a$, typically between 1 and 1.5, accounts for entrance and exit losses from the bundle and $n_r$ and $K_r$ are the number of rows, and loss factor per row, respectively. They provide graphs for determining $K_r$ as a function of tube arrangement, pitch ratios, and Reynolds number. G. F. Hewitt [*Heat Exchanger Design Handbook, Part 2, Fluid Mechanics and Heat Transfer,* Begell House, New York, 2008] provides regression equations for $K_r$.

For *extended surfaces,* which include fins mounted perpendicular to the tubes or spiral-wound fins, pin fins, plate fins, and so on, friction data for the specific surface involved should be used. For details, see W. M. Kays and A. L. London [*Compact Heat Exchangers,* 2d ed., McGraw-Hill, New York, 1964]. If specific data are unavailable, the correlation by A. Y. Gunter and W. A. Shaw [*Trans. ASME* **67:** 643–660 (1945)] may be used as an approximation.

When a large temperature change occurs in a gas flowing across a tube bundle, gas properties should be evaluated at the mean temperature

$$T_m = T_t + K\Delta T_{lm} \tag{6-170}$$

where $T_t$ = average tube-wall temperature
$K$ = constant
$\Delta T_{lm}$ = log-mean temperature difference between gas and tubes

Values of $K$ averaged from the recommendations of T. H. Chilton and R. P. Genereaux [*Trans. AIChE* **29:** 151–173 (1933)] and E. D. Grimison [*Trans. ASME* **59:** 583–594 (1937)] are as follows: for in-line tubes, 0.9 for cooling and −0.9 for heating; for staggered tubes, 0.75 for cooling and −0.8 for heating.

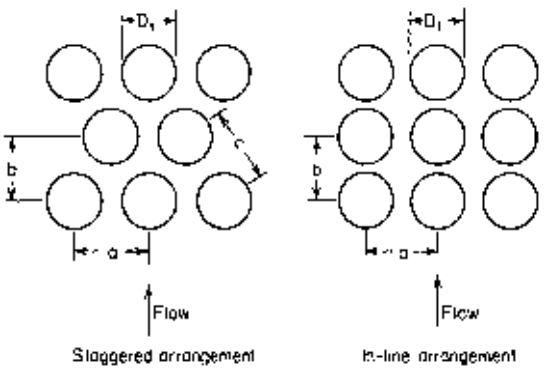

**FIG. 6-41** Tube-bank configurations.

For nonisothermal flow of *liquids* across tube bundles, the friction factor is increased if the liquid is being cooled and is decreased if the liquid is being heated. The factors previously given for nonisothermal flow of liquids in pipes (Incompressible Flow in Pipes and Channels) should be used.

For two-phase gas/liquid horizontal crossflow through tube banks, the method of J. E. Diehl and C. H. Unruh [*Pet. Refiner* **37**(10): 124–128 (1958)] is available. For laminar flow of nonnewtonian fluids across tube banks, see D. Adams and K. J. Bell [*Chem. Eng. Prog.* **64;** *Symp. Ser.* **82:** 133–145 (1968)].

Flow-induced *tube vibration* occurs at critical fluid velocities through tube banks, and it is to be avoided because of the severe damage that can result. Methods to predict and correct vibration problems may be found in F. L. Eisinger [*Trans. ASME J. Pressure Vessel Tech.* **102:** 138–145 (May 1980)] and S. S. Chen [*J. Sound Vibration* **93:** 439–455 (1984)].

## BEDS OF SOLIDS

**Fixed Beds of Granular Solids** Frictional pressure-drop prediction is complicated by the variety of granular materials and of their packing arrangement. For flow of a *single incompressible fluid* through an incompressible bed of granular solids, the pressure drop may be estimated by the correlation given in Fig. 6-42 [M. Leva, *Chem. Eng.* **56**(5): 115–117 (1949), or *Fluidization,* McGraw-Hill, New York, 1959]. The modified friction factor and Reynolds number are defined by

$$f_m = \frac{D_p\rho\phi_s\varepsilon^3\Delta p}{2G^2L(1-\varepsilon)^{3-n}} \tag{6-171}$$

$$\mathrm{Re}' \equiv \frac{D_pV\rho}{\mu} \tag{6-172}$$

where $\Delta p$ = frictional pressure drop
$L$ = depth of bed
$D_p$ = average particle diameter, defined as diameter of a sphere of same volume as particle
$\varepsilon$ = void fraction
$n$ = exponent given in Fig. 6-42 as a function of Re′
$\phi_s$ = shape factor defined as the area of sphere of diameter $D_p$ divided by the actual surface area of the particle
$V$ = fluid superficial velocity based on the empty chamber cross section
$\rho$ = fluid density
$\mu$ = fluid viscosity

In creeping flow (Re′ < 10),

$$f_m = \frac{100}{\mathrm{Re}'} \tag{6-173}$$

At high Reynolds numbers, the friction factor becomes nearly constant, approaching a value on the order of unity for most packed beds.

In terms of $S$, particle surface area per unit volume of bed is

$$D_p = \frac{6(1-\varepsilon)}{\phi_s S} \tag{6-174}$$

A simpler, widely used correlation is the Ergun equation [S. Ergun, *Chem. Eng. Progr.* **48:** 89–94 (1952)]

$$f_p = \frac{150}{\mathrm{Re}_p} + 1.75 \tag{6-175}$$

where the packed-bed friction factor and Reynolds number are defined, respectively, by

$$f_p = \frac{\Delta pD_p\varepsilon^3}{\rho V^2L(1-\varepsilon)} \tag{6-176}$$

$$\mathrm{Re}_p = \frac{D_pV\rho}{(1-\varepsilon)\mu} \tag{6-177}$$

and the other variables are the same as those defined after Eq. (6-172) except that the equivalent particle diameter is given by

$$D_p = \frac{6}{a_V} \tag{6-178}$$

where $a_V$ is the surface-to-volume ratio of the particle. Equation (6-178) reduces to the sphere diameter for spherical particles.

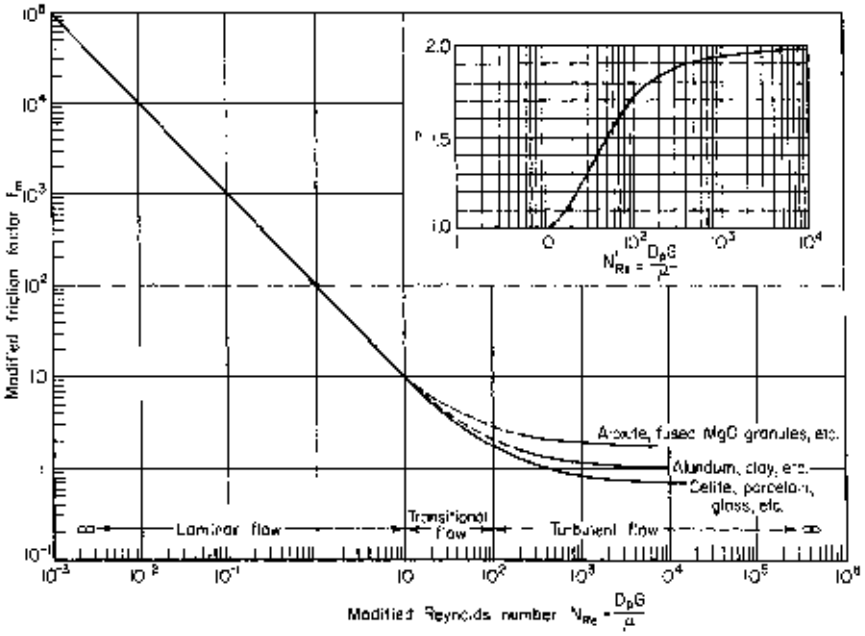

**FIG. 6-42** Friction factor for beds of solids. [From M. Leva, *Fluidization*, McGraw-Hill, New York, 1959, p. 49.]

**Porous Media** Packed beds of granular solids are one type of the general class referred to as *porous media,* which include geological formations such as petroleum reservoirs and aquifers, manufactured materials such as sintered metals and porous catalysts, burning coal or char particles, and textile fabrics, to name a few. Pressure drop for incompressible flow across a porous medium has the same qualitative behavior as that for packed beds of solids. At low Reynolds numbers, viscous forces dominate and pressure drop is proportional to fluid viscosity and superficial velocity; and at high Reynolds numbers, pressure drop is proportional to fluid density and to the square of superficial velocity.

Creeping flow ($\mathrm{Re}' < \approx 1$) through porous media is often described in terms of the *permeability* $k$ and Darcy's law:

$$-\frac{\Delta p}{L} = \frac{\mu}{k} V \tag{6-179}$$

where $V$ = superficial velocity. The SI units for permeability are square meters. Creeping flow conditions generally prevail in geological porous media. For *multidimensional flows* through *isotropic* porous media, the superficial velocity **V** and pressure gradient $\nabla p$ vectors replace the corresponding one-dimensional variables in Eq. (6-179).

$$\nabla p = -\frac{\mu}{k}\mathbf{V} \tag{6-180}$$

For isotropic homogeneous porous media (uniform permeability and porosity), the pressure for creeping incompressible single phase-flow may be shown to satisfy the Laplace equation:

$$\nabla^2 p = 0 \tag{6-181}$$

For *anisotropic* or *oriented* porous media, as are frequently found in geological media, permeability varies with direction and a ***permeability tensor*** **K** may be introduced [J. C. Slattery, *Momentum, Energy and Mass Transfer in Continua,* Krieger, Huntington, N.Y., 1981, p. 194]. Solutions for Darcy's law for several geometries of interest in petroleum reservoirs and aquifers, for both incompressible and compressible flows, are given in B. C. Craft and M. Hawkins [*Applied Petroleum Reservoir Engineering,* Prentice-Hall, Englewood Cliffs, N.J., 1959]. See also D. K. Todd [*Groundwater Hydrology,* 2d ed., Wiley, New York, 1980].

For granular solids of *mixed size* the average particle diameter may be calculated as

$$\frac{1}{D_p} = \sum_i \frac{x_i}{D_{p,i}} \tag{6-182}$$

where $x_i$ = weight fraction of particles of size $D_{p,i}$.

For *isothermal compressible flow* of a gas with constant compressibility factor $Z$ through a packed bed of granular solids, an equation similar to Eq. (6-115) for pipe flow may be derived:

$$p_1^2 - p_2^2 = \frac{2ZRG^2T}{M_w}\left[\ln\frac{v_2}{v_1} + \frac{2f_m L(1-\varepsilon)^{3-n}}{\phi_s^{3-n}\varepsilon^3 D_p}\right] \tag{6-183}$$

where $p_1$ = upstream absolute pressure
$p_2$ = downstream absolute pressure
$R$ = gas constant
$T$ = absolute temperature
$M_w$ = molecular weight
$v_1$ = upstream specific volume of gas
$v_2$ = downstream specific volume of gas

For creeping flow of *power law* nonnewtonian fluids, the method of R. H. Christopher and S. Middleman [*Ind. Eng. Chem. Fundam.* **4:** 422–426 (1965)] may be used:

$$-\Delta p = \frac{150HLV^n(1-\varepsilon)^2}{D_p^2\phi_s^2\varepsilon^3} \tag{6-184}$$

$$H = \frac{K}{12}\left(9+\frac{3}{n}\right)^n\left[\frac{D_p^2\phi_s^2\varepsilon^4}{(1-\varepsilon)^2}\right]^{(1-n)/2} \tag{6-185}$$

where $V = G/\rho$ = superficial velocity, $K$ and $n$ = power law material constants, and all other variables are as defined after Eq. (6-172). This correlation is supported by data from R. H. Christopher and S. Middleman (1965), D. R. Gregory and R. G. Griskey [*AIChE J.* **13:** 122–125 (1967)], Y. H. Yu et al. [*Can. J. Chem. Eng.* **46:** 149–154 (1968)], N. Siskovic et al. [*AIChE J.* **17:** 281–285 (1971)], Z. Kemblowski and J. Mertl [*Chem. Eng. Sci.* **29:** 213–223 (1974)], and Z. Kemblowski and M. Dziuminski [*Rheol. Acta* **17:** 176–187 (1978)]. The measurements cover the range $n = 0.50$ to 1.60, and modified Reynolds number $\mathrm{Re}' = 10^{-8}$ to 10, where

$$\mathrm{Re}' = \frac{D_p V^{2-n}\rho}{H} \tag{6-186}$$

For the case $n = 1$ (newtonian fluid), Eqs. (6-184) and (6-185) give a pressure drop 25 percent less than that given by Eqs. (6-171) through (6-173).

For *viscoelastic fluids* see R. J. Marshall and A. B. Metzner [*Ind. Eng. Chem. Fundam.* **6:** 393–400 (1967)], D. R. Gregory and R. G. Griskey [*AIChE J.* **13:** 122–125 (1967)], and Z. Kemblowski and M. Dziubinski [*Rheol. Acta* **17:** 176–187 (1978)].

For gas flow through porous media with small pore diameters, the slip flow and molecular flow equations previously given (see the Vacuum Flow subsection) may be applied when the pore is of the same or smaller order as the mean free path.

**Tower Packings** For the flow of a *single fluid* through a bed of tower packing, pressure drop may be estimated using the preceding methods. See also Sec. 14 of this handbook. For *countercurrent gas/liquid flow* in commercial tower packings, both structured and unstructured, several sources of data and correlations for pressure drop and flooding are available. See, for example, R. F. Strigle [*Random Packings and Packed Towers, Design and Applications*, Gulf Publishing, Houston, Tex., 1989; *Chem. Eng. Prog.* **89**(8): 79–83 (August 1993)], G. A. Hughmark [*Ind. Eng. Chem. Fundam.* **25:** 405–409 (1986)], J. J. J. Chen [*Chem. Eng. Sci.* **40:** 2139–2140 (1985)], R. Billet and J. Mackowiak [*Chem. Eng. Technol.* **11:** 213–217 (1988)], H. Krehenwinkel and H. Knapp [*Chem. Eng. Technol.* **10:** 231–242 (1987)], A. Mersmann and A. Deixler [*Ger. Chem. Eng.* **9:** 265–276 (1986)]. Data and correlations for flooding and pressure drop for structured packings are given by J. R. Fair and J. R. Bravo [*Chem. Eng. Progr.* **86**(1): 19–29 (January 1990)].

**Fluidized Beds** When gas or liquid flows upward through a vertically unconstrained bed of particles, there is a minimum fluid velocity at which the particles will begin to move. Above this minimum velocity, the bed is said to be *fluidized*. Fluidized beds are widely used, in part because of their excellent mixing and heat- and mass-transfer characteristics. See Sec. 17 of this handbook for detailed information.

## BOUNDARY LAYER FLOWS

In boundary layer flow, the flow far from the surface of an object is inviscid, and the effects of viscosity are manifest only in a thin region near the surface where steep velocity gradients occur to satisfy the no-slip condition at the solid surface. The thin layer where the velocity decreases from the inviscid, potential flow velocity to zero (relative velocity) at the solid surface is called the *boundary layer*. Boundary layer thickness is indefinite because the velocity asymptotically approaches the free-stream velocity at the outer edge. The boundary layer thickness is conventionally taken to be the distance at which the velocity equals 0.99 times the free-stream velocity. The boundary layer may be either laminar or turbulent. In the former case, the equations of motion may be simplified by scaling arguments. H. Schlichting and K. Gersten [*Boundary Layer Theory,* 8th ed. rev., Springer-Verlag, Berlin, 2003] is the most comprehensive source for information on boundary layer flows.

**Flat Plate, Zero Angle of Incidence** For flow over a wide, thin flat plate at zero angle of incidence with a uniform free-stream velocity, as shown in Fig. 6-43, the *critical Reynolds number* at which the boundary layer becomes turbulent is normally taken to be

$$\mathrm{Re}_x = \frac{xV\rho}{\mu} = 500{,}000 \tag{6-187}$$

where $V$ = free-stream velocity
$\rho$ = fluid density
$\mu$ = fluid viscosity
$x$ = distance from leading edge of plate

However, the transition Reynolds number depends on free-stream turbulence and may range from $3 \times 10^5$ to $3 \times 10^6$. The *laminar boundary layer* thickness $\delta$ is a function of distance from the leading edge:

$$\delta \approx 5.0x\mathrm{Re}_x^{-0.5} \tag{6-188}$$

The total drag on the plate of length $L$ and width $b$ for a laminar boundary layer, including the drag on both surfaces, is

$$F_D = 1.328bL\rho V^2\,\mathrm{Re}_L^{-0.5} \tag{6-189}$$

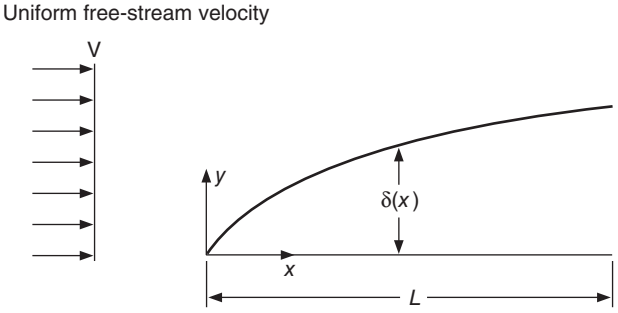

**FIG. 6-43** Boundary layer on a flat plate at zero angle of incidence.

For *nonnewtonian power law fluids* [A. Acrivos et al., *AIChE J.* **6:** 312–317 (1960); Hsu, *AIChE J.* **15:** 367–370 (1969)],

$$F_D = CbL\rho V^2\mathrm{Re}_L'^{\,-1/(1+n)} \tag{6-190}$$

| $n$ = | 0.2 | 0.3 | 0.4 | 0.5 | 0.6 | 0.7 | 0.8 | 0.9 | 1 |
|---|---|---|---|---|---|---|---|---|---|
| $C$ = | 2.075 | 1.958 | 1.838 | 1.727 | 1.627 | 1.538 | 1.460 | 1.390 | 1.328 |

where $\mathrm{Re}_L' = \rho V^{2-n}L^n/K$ and $K$ and $n$ are the power law material constants (see Eq. (6-4)).

For a *turbulent boundary layer,* the thickness may be estimated as

$$\delta \approx 0.37x\mathrm{Re}_x^{-0.2} \tag{6-191}$$

and the total drag force on both sides of the plate of length $L$ is

$$F_D = \left[\frac{0.455}{(\log \mathrm{Re}_L)^{2.58}} - \frac{1{,}700}{\mathrm{Re}_L}\right]\rho bLV^2 \quad 5\times10^5 < \mathrm{Re}_L < 10^9 \tag{6-192}$$

Here the second term accounts for the laminar leading edge of the boundary layer and assumes that the critical Reynolds number is 500,000.

**Cylindrical Boundary Layer** Laminar boundary layers on cylindrical surfaces, with flow parallel to the cylinder axis, are described by M. B. Glauert and M. J. Lighthill [*Proc. R. Soc.* (*London*), **230A:** 188–203 (1955)], N. A. Jaffe and T. T. Okamura [*Z. Angew. Math. Phys.* **19:** 564–574 (1968)], and K. Stewartson [*Q. Appl. Math.* **13:** 113–122 (1955)]. For a turbulent boundary layer, the total drag may be estimated as

$$F_D = \bar{c}_f \pi rL\rho V^2 \tag{6-193}$$

where $r$ = cylinder radius, $L$ = cylinder length, and the average friction coefficient is given by [F. M. White, *J. Basic Eng.* **94:** 200–206 (1972)]

$$\bar{c}_f = 0.0015 + \left[0.30 + 0.015\left(\frac{L}{r}\right)^{0.4}\right]\mathrm{Re}_L^{-1/3} \tag{6-194}$$

for $\mathrm{Re}_L = 10^6$ to $10^9$ and $L/r < 10^6$.

**Continuous Flat Surface** Boundary layers on continuous surfaces drawn through a stagnant fluid are shown in Fig. 6-44. Figure 6-44*a* shows the continuous flat surface [B. C. Sakiadis, *AIChE J.* **7:** 26–28, 221–225, 467–472 (1961)]. The critical Reynolds number for transition to turbulent flow may be greater than the 500,000 value for the finite flat-plate case discussed previously [F. K. Tsou et al., *J. Fluid Mech.* **26:** 145–161 (1966)]. For a laminar boundary layer, the thickness is given by

$$\delta = 6.37x\mathrm{Re}_x^{-0.5} \tag{6-195}$$

and the total drag exerted on the two surfaces is

$$F_D = 1.776bL\rho V^2\,\mathrm{Re}_L^{-0.5} \tag{6-196}$$

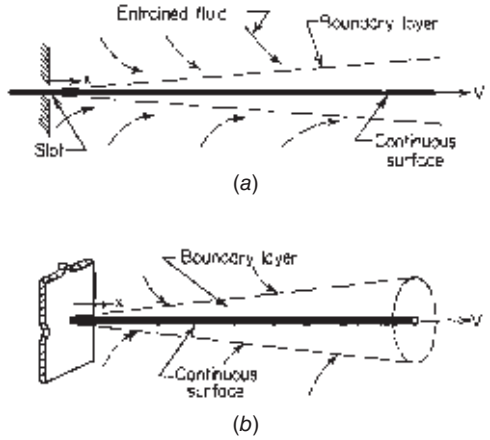

**FIG. 6-44** Continuous surface: (*a*) continuous flat surface, (*b*) continuous cylindrical surface. [From B. C. Sakiadis, *Am. Inst. Chem. Eng. J.*, **7,** 221, 467 (1961).]

The total flow rate of fluid entrained by the surface is

$$q = 3.232Blv\,\mathrm{Re}_L^{-0.5} \tag{6-197}$$

The theoretical velocity field was experimentally verified by F. K. Tsou et al. [*Int. J. Heat Mass Transfer* **10:** 219–235 (1967)] and A. Z. Szeri et al. [*J. Lubr. Technol.* **98:** 145–156 (1976)]. For *nonnewtonian power law fluids* see V. G. Fox et al. [*AIChE J.* **15:** 327–333 (1969)].

For a turbulent boundary layer, the thickness is given by

$$\delta = 1.01x\mathrm{Re}_x^{-0.2} \tag{6-198}$$

and the total drag on both sides by

$$F_D = 0.056bL\rho V^2\,\mathrm{Re}_L^{-0.2} \tag{6-199}$$

and the total entrainment by

$$q = 0.252Blv\,\mathrm{Re}_L^{-0.2} \tag{6-200}$$

When the laminar boundary layer is a significant part of the total length of the object, the total drag should be corrected by subtracting a calculated turbulent drag for the length of the laminar section and then adding the laminar drag for the laminar section. F. K. Tsou et al. [*Int. J. Heat Mass Transfer* **10:** 219–235 (1967)] give an improved analysis of the turbulent boundary layer; their data indicate that Eq. (6-199) underestimates the drag by about 15 percent.

**Continuous Cylindrical Surface** The continuous surface shown in Fig. 6-44*b* is applicable, for example, for a wire drawn through a stagnant fluid [B. C. Sakiadis, *AIChE J.* **7:** 26–28, 221–225, 467–472 (1961); G. Vasudevan and S. Middleman, *AIChE J.* **16:** 614 (1970)]. The critical-length Reynolds number for transition is $\mathrm{Re}_x = 200{,}000$. The laminar boundary layer thickness, total drag, and entrainment flow rate may be obtained from Fig. 6-45. The normalized boundary layer thickness and integral friction coefficient are from G. Vasudevan and S. Middleman (1970), who used a similarity solution of the boundary layer equations. The drag force over a length $x$ is given by

$$F_D = \bar{C}_f x \frac{\rho V^2}{2} 2\pi r_o \tag{6-201}$$

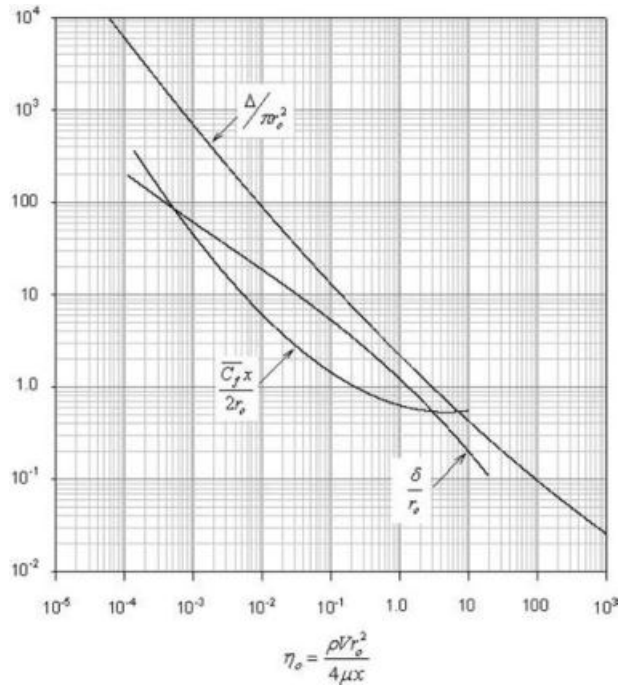

**FIG. 6-45** Boundary layer parameters for continuous cylindrical surfaces. [$\Delta/\pi r_o^2$ is from B. C. Sakiadis, *Am. Inst. Chem. Engr. J.*, **7,** 467 (1961); $\bar{C}_f x/2r_o$ and $\delta/r_o$ are from G. Vasudevan and S. Middleman, *Am. Inst. Chem. Eng. J.*, **16**, 614 (1970).]

The entrainment flow rate is from B. C. Sakiadis [*AIChE J.* **7:** 26–28, 221–225, 467–472 (1961)], who used an integral momentum approximation rather than the exact similarity solution.

$$q = V\Delta \tag{6-202}$$

Further laminar boundary layer analysis is given by L. J. Crane [*Z. Angew. Math. Phys.* **23:** 201–212 (1972)].

For a turbulent boundary layer, the total drag may be roughly estimated using Eqs. (6-193) and (6-194) for finite cylinders. Measured forces by Y. D. Kwon and D. C. Prevorsek [*J. Eng. Ind.* **101:** 73–79 (1979)] are greater than predicted this way.

The laminar boundary layer on *deforming continuous surfaces* with velocity varying with axial position is discussed by J. Vleggaar [*Chem. Eng. Sci.* **32:** 1517–1525 (1977)] and L. J. Crane [*Z. Angew. Math. Phys.* **26:** 619–622 (1975)].

## VORTEX SHEDDING

When fluid flows past objects or through orifices or similar restrictions, vortices may periodically be shed downstream. Objects such as smokestacks, chemical processing columns, suspended pipelines, and electrical transmission lines can be subjected to damaging vibrations and forces due to the vortices, especially if the shedding frequency is close to a natural vibration frequency of the object. The shedding can also produce sound. See M. Z. von Krzywoblocki [*Appl. Mech. Rev.* **6:** 393–397 (1953)] and A. W. Marris [*J. Basic Eng.* **86:** 185–196 (1964)].

Development of a vortex street, or *von Kármán vortex street,* is shown in Fig. 6-46. Discussions of the vortex street may be found in R. L. Panton [*Incompressible Flow,* Wiley, New York, 1984]. The Reynolds number is

$$\mathrm{Re} = \frac{DV\rho}{\mu} \tag{6-203}$$

where $D$ = diameter of cylinder or effective width of object
$V$ = free-stream velocity
$\rho$ = fluid density
$\mu$ = fluid viscosity

For flow past a cylinder, the vortex street forms at Reynolds numbers above about 40. The vortices initially form in the wake, the point of formation moving closer to the cylinder as Re is increased. At a Reynolds number of 60 to 100, the vortices are formed from eddies attached to the cylinder surface. The vortices move at a velocity slightly less than $V$. The frequency of vortex shedding $f$ is given in terms of the Strouhal number, which is approximately constant over a wide range of Reynolds numbers.

$$\mathrm{Sr} \equiv \frac{fD}{V} \tag{6-204}$$

For $40 < \mathrm{Re} < 200$ the vortices are laminar and the Strouhal number has a nearly constant value of 0.2 for flow past a cylinder. Between Re = 200 and 400, Sr is no longer constant and the wake becomes irregular. Above about Re = 400 the vortices become turbulent, the wake is once again stable, and Sr remains constant at about 0.2 up to a Reynolds number of about $10^5$. Above $\mathrm{Re} = 10^5$ the vortex shedding is difficult to see in flow visualization experiments, but velocity measurements still show a strong spectral component at Sr = 0.2 (Panton, p. 392). The vortex street may disappear over the range $5 \times 10^5 < \mathrm{Re} < 3.5 \times 10^6$, but reestablishes above $3.5 \times 10^6$.

Vortex shedding exerts alternating lateral forces on a cylinder. Such forces may lead to severe vibration or mechanical failure of cylindrical elements such as heat-exchanger tubes, transmission lines, stacks, and columns when the vortex shedding frequency is close to resonant bending frequency. According to J. P. Den Hartog [*Proc. Nat. Acad. Sci.* **40:** 155–157 (1954)], the vortex shedding and cylinder vibration frequency will shift to the resonant frequency when the calculated shedding frequency is within 20 percent of the resonant frequency. The well-known Tacoma Narrows bridge collapse resulted from resonance between a torsional oscillation and

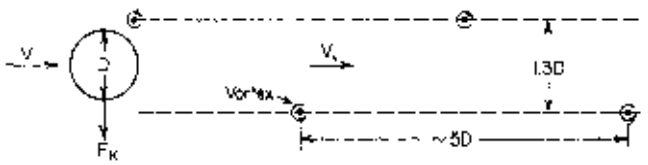

**FIG. 6-46** Vortex street behind a cylinder.

vortex shedding (R. L. Panton, *Incompressible Flow,* Wiley, New York, 1984, p. 392). Spiral strakes are sometimes installed on tall stacks so that vortices at different axial positions are not shed simultaneously. The alternating lateral force $F_K$, sometimes called the *von Kármán force,* is given by [J. P. Den Hartog, *Mechanical Vibrations,* 4th ed., McGraw-Hill, New York, 1956, pp. 305–309]

$$F_K = C_K A \frac{\rho V^2}{2} \tag{6-205}$$

where $C_K$ = von Kármán coefficient
$A$ = projected area perpendicular to flow
$\rho$ = fluid density
$V$ = free-stream fluid velocity

For a cylinder, $C_K = 1.7$. For a vibrating cylinder, the effective projected area exceeds, but is always less than twice, the actual cylinder projected area [H. Rouse, *Engineering Hydraulics,* Wiley, New York, 1950].

The following references pertain to discussions of vortex shedding in specific structures: steel stacks [M. S. Osker and J. O. Smith, *Trans. ASME,* **78:** 1381–1391 (1956); J. O. Smith and J. H. McCarthy, *Mech. Eng.* **87:** 38–41 (1965)]; heat exchangers [F. L. Eisinger, *Trans. ASME J. Pressure Vessel Tech.* **102:** 138–145 (May 1980); S. S. Chen, *J. Sound Vibration* **93:** 439–455 (1984); N. R. Gainsboro, *Chem. Eng. Prog.* **64**(3): 85–88 (1968); "Flow-Induced Vibration in Heat Exchangers," *Symp. Proc.* ASME, New York, 1970]; suspended pipe lines [R. C. Baird, *Trans. ASME,* **77:** 797–804 (1955)]; and suspended cable [R. F. Steidel, *J. Appl. Mech.* **23:** 649–650 (1956)].

## COATING FLOWS

In coating flows, liquid films are entrained on moving solid surfaces. For general discussions, see K. J. Ruschak [*Ann. Rev. Fluid Mech.* **17:** 65–89 (1985)], E. D. Cohen and E. B. Gutoff [*Modern Coating and Drying Technology,* VCH Publishers, New York, 1992], and S. Middleman [*Fundamentals of Polymer Processing,* McGraw-Hill, New York, 1977]. It is generally important to control the thickness and uniformity of the coatings.

In *dip coating,* or *free withdrawal coating*, a solid surface is withdrawn from a liquid pool, as shown in Fig. 6-47. It illustrates many of the features found in other coating flows as well. J. A. Tallmadge and C. Gutfinger [*Ind. Eng. Chem.* **59**(11): 19–34 (1967)] provide an early review of the theory of dip coating. The coating flow rate and film thickness are controlled by the withdrawal rate and the flow behavior in the meniscus region. For a withdrawal velocity $V$ and an angle of inclination from the horizontal $\phi$, the film thickness $h$ may be estimated for low withdrawal velocities by

$$h\left(\frac{\rho g}{\sigma}\right)^{1/2} = \frac{0.944}{(1-\cos\varphi)^{1/2}}\mathrm{Ca}^{2/3} \tag{6-206}$$

where $g$ = acceleration of gravity
$\mathrm{Ca} = \mu V/\sigma$ = capillary number
$\mu$ = viscosity
$\sigma$ = surface tension

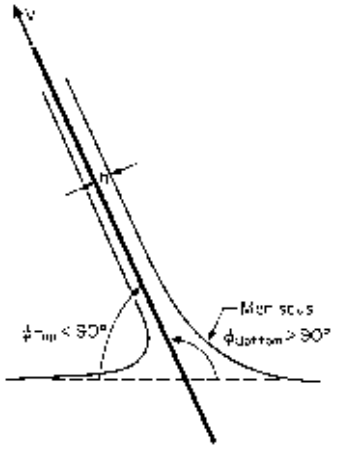

**FIG. 6-47** Dip coating.

Equation (6-206) is asymptotically valid as $\mathrm{Ca} \to 0$ and agrees with experimental data up to capillary numbers in the range of 0.01 to 0.03. In practice, where high production rates require high withdrawal speeds, capillary numbers are usually too large for Eq. (6-206) to apply. Approximate analytical methods for larger capillary numbers have been obtained by numerous investigators, but none appears wholly satisfactory, and some are based on questionable assumptions [K. J. Ruschak, *Ann. Rev. Fluid Mech.* **17:** 65–89 (1985)]. With the availability of high-speed computers and the development of the field of computational fluid dynamics, numerical solutions accounting for two-dimensional flow aspects, along with gravitational, viscous, inertial, and surface tension forces, are now the most effective means to analyze coating flow problems.

Other common coating flows include premetered flows, such as *slide* and *curtain coating,* where the film thickness is an independent parameter that may be controlled within limits, and the curvature of the meniscus adjusts accordingly; the closely related *blade coating*; and *roll coating* and *extrusion coating.* See K. J. Ruschak [*Ann. Rev. Fluid Mech.* **17:** 65–89 (1985)], E. D. Cohen and E. B. Gutoff [*Modern Coating and Drying Technology,* VCH Publishers, New York, 1992], and S. Middleman [*Fundamentals of Polymer Processing,* McGraw-Hill, New York, 1977]. For dip coating of wires, see P. Tauguy et al. [*Int. J. Numerical Meth. Fluids* **4:** 441–475 (1984)].

Many coating flows are subject to instabilities that lead to defects. Three-dimensional flow instabilities lead to such problems as *ribbing.* Air entrainment is another common defect.

## FALLING FILMS

**Minimum Wetting Rate** The minimum liquid rate required for complete wetting of a vertical surface is about 0.03 to 0.3 kg/m · s (0.02 to 0.2 lbm/ft · s) for water at room temperature. The minimum rate depends on the geometry and nature of the vertical surface, surface tension, and mass transfer between surrounding gas and the liquid. See A. B. Ponter et al. [*Int. J. Heat Mass Transfer* **10:** 349–359 (1967); *Trans. Inst. Chem. Eng.* (*London*) **45:** 345–352 (1967)], F. P. Stainthorpe and J. M. Allen [*Trans. Inst. Chem. Eng.* (*London*) **43:** 85–91 (1967)] and K. Watanabe et al. [ *J. Chem. Eng.* (*Japan*) **8**(1): 75 (1975)].

**Laminar Flow** For films on *vertical flat surfaces,* as shown in Fig. 6-48, or vertical tubes with small film thickness compared to tube radius, laminar flow conditions prevail for Reynolds numbers less than about 2000, where the Reynolds number is given by

$$\mathrm{Re} = \frac{4\Gamma}{\mu} \tag{6-207}$$

where $\Gamma$ = liquid mass flow rate per unit width of surface and $\mu$ = liquid viscosity. For a flat film surface, the film thickness $\delta$ is

$$\delta = \left(\frac{3\Gamma\mu}{\rho^2 g}\right)^{1/3} \tag{6-208}$$

and the average film velocity is

$$V = \frac{\Gamma}{\rho\delta} = \frac{g\rho\delta^2}{3\mu} \tag{6-209}$$

The downward velocity profile $u(x)$, where $x = 0$ at the liquid/gas interface and $x = \delta$ at the solid surface, is given by

$$u = 1.5V\left[1 - \left(\frac{x}{\delta}\right)^2\right] \tag{6-210}$$

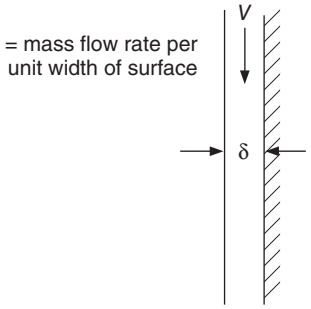

**FIG. 6-48** Falling film.

These equations assume that there is no drag force at the gas/liquid interface, such as would be produced by gas flow. For a flat surface *inclined* at an angle θ with the horizontal, the preceding equations may be modified by replacing $g$ by $g \sin \theta$. For films falling inside vertical tubes with film thickness up to and including the full pipe radius, see M. L. Jackson [*AIChE J.* **1:** 231–240 (1955)].

These equations have generally given good agreement with experimental results for low-viscosity liquids (< 0.005 Pa·s or < 0.5 cP) whereas Jackson found film thicknesses for higher-viscosity liquids (0.01 to 0.02 Pa·s, 10 to 20 cP) were significantly less than predicted by Eq. (6-208). At Reynolds numbers of 25 or greater, *surface waves* will be present on the liquid film. D. West and R. Cole [*Chem. Eng. Sci.* **22:** 1388–1389 (1967)] found that the surface velocity $u$ is still within ±7 percent of that given by Eq. (6-210) even in wavy flow.

For laminar nonnewtonian film flow, see R. B. Bird et al. [*Dynamics of Polymeric Liquids,* vol. 1: *Fluid Mechanics,* Wiley, New York, 1977, pp. 215, 217], G. Astarita et al. [*Ind. Eng. Chem. Fundam.* **3:** 333–339 (1964)] and D. C. H. Cheng [*Ind. Eng. Chem. Fundam.* **13:** 394–395 (1974)].

**Turbulent Flow** In turbulent flow, Re > 2000, for vertical surfaces, the film thickness may be estimated to within ±25 percent using

$$\delta = 0.304\left(\frac{\Gamma^{1.75}\mu^{0.25}}{\rho^2 g}\right)^{1/3} \tag{6-211}$$

Replace $g$ by $g \sin \theta$ for a surface inclined at angle θ to the horizontal. The average film velocity is $V = \Gamma/\rho\delta$.

J. A. Tallmadge and C. Gutfinger [*Ind. Eng. Chem.* **59**(11): 19–34 (1967)] discuss prediction of drainage rates from liquid films on flat and cylindrical surfaces.

**Effect of Surface Traction** If drag is exerted on the surface of the film because of motion of the surrounding fluid, the film thickness will be reduced or increased, depending upon whether the drag acts with or against gravity. W. J. Thomas and S. Portalski [*Ind. Eng. Chem.* **50:** 1081–1088 (1958)], A. E. Dukler [*Chem. Eng. Prog.* **55**(10): 62–67 (1959)], and P. G. Kosky [*Int. J. Heat Mass Transfer,* **14:** 1220–1224 (1971)] have presented calculations of film thickness and film velocity. Film thickness data for falling water films with cocurrent and countercurrent airflow in pipes are given by L. Y. Zhivaikin [*Int. Chem. Eng.* **2:** 337–341 (1962)]. G. J. Zabaras et al. [*AIChE J.* **32:** 829–843 (1986)] and G. J. Zabaras and A. E. Dukler [*AIChE J.* **34:** 389–396 (1988)] present studies of film flow in vertical tubes with both cocurrent and countercurrent gas flow, including measurements of film thickness, wall shear stress, wave velocity, wave amplitude, pressure drop, and flooding point for countercurrent flow.

**Flooding** With countercurrent gas flow, a condition is reached with increasing gas rate for which flow reversal occurs and liquid is carried upward. The mechanism for this flooding condition most often has been attributed to waves either bridging the pipe or reversing direction to flow upward at flooding. However, the results of Zabaras and Dukler suggest that flooding may be controlled by flow conditions at the liquid inlet and that wave bridging or upward wave motion does not occur, at least for the 50.8-mm-diameter pipe used for their study. Flooding mechanisms are still incompletely understood. Under some circumstances, such as when the gas is allowed to develop its normal velocity profile in a "calming length" of pipe beneath the liquid draw-off, the gas superficial velocity at flooding will be increased, and increases with decreasing length of wetted pipe [G. F. Hewitt et al., *Proc. Two-Phase Flow Symp.,* University of Exeter Exeter, UK, paper 4H, AERE-4 4614 (1965)]. A bevel cut at the bottom of the pipe with an angle 30° from the vertical will increase the flooding velocity in small-diameter tubes at moderate liquid flow rates. If the gas approaches the tube from the side, the taper should be oriented with the point facing the gas entrance. Figures 6-49 and 6-50 give correlations for flooding in tubes with square and slant bottoms (courtesy Holmes, DuPont Co.) The superficial mass velocities of gas and liquid $G_G$ and $G_L$ and the physical property parameters λ and ψ are the same as those defined for the Baker chart (Multiphase Flow subsection, Fig. 6-25). For tubes larger than 50 mm (2 in), flooding velocity appears to be relatively insensitive to diameter and the flooding curves for 1.98-in diameter may be used.

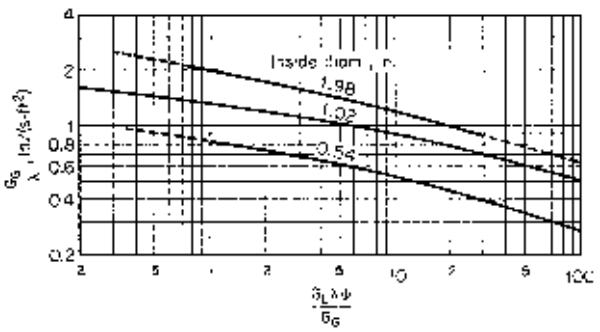

**FIG. 6-49** Flooding in vertical tubes with square top and square bottom. To convert lbm/(ft²·s) to kg/(m²·s), multiply by 4.8824; to convert in to mm, multiply by 25.4. [*Courtesy of E. I. du Pont de Nemours & Co.*]

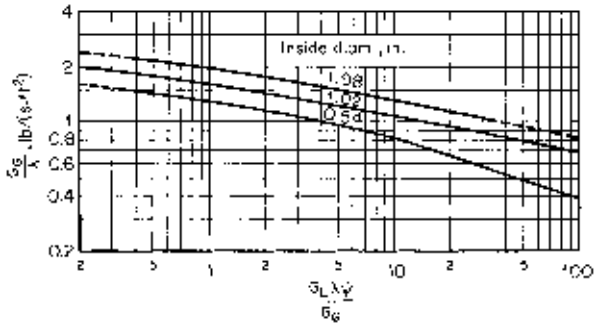

**FIG. 6-50** Flooding in vertical tubes with square top and slant bottom. To convert lbm/(ft²·s) to kg/(m²·s), multiply by 4.8824; to convert in to mm, multiply by 25.4. [*Courtesy of E. I. du Pont de Nemours & Co.*]

## HYDRAULIC TRANSIENTS

Many transient flows of liquids may be analyzed by using the full time-dependent equations of motion for incompressible flow. However, some phenomena are controlled by the small compressibility of liquids. These phenomena are generally called *hydraulic transients.*

**Water Hammer** When liquid flowing in a pipe is suddenly decelerated to zero velocity by a fast-closing valve, a pressure wave propagates upstream to the pipe inlet, where it is reflected; a pounding of the line commonly known as *water hammer* is often produced. For an instantaneous flow stoppage of a truly incompressible fluid in an inelastic pipe, the pressure rise would be infinite. Finite compressibility of the fluid and elasticity of the pipe limit the pressure rise to a finite value. The Joukowski formula gives the maximum pressure rise as

$$\Delta p = \rho a\, \Delta V \tag{6-212}$$

where ρ = liquid density
$\Delta V$ = change in liquid velocity
$a$ = pressure wave velocity

The wave velocity is given by

$$a = \frac{\sqrt{\beta/\rho}}{\sqrt{1+(\beta/E)(D/b)}} \tag{6-213}$$

where β = liquid bulk modulus of elasticity
$E$ = elastic modulus of pipe wall
$D$ = pipe inside diameter
$b$ = pipe wall thickness

The numerator gives the wave velocity for perfectly rigid pipe, and the denominator corrects for wall elasticity. This formula is for thin-walled pipes; for thick-walled pipes, the factor $D/b$ is replaced by

$$2\frac{D_o^2 + D_i^2}{D_o^2 - D_i^2}$$

where $D_o$ = pipe outside diameter
$D_i$ = pipe inside diameter

***Example 6-10 Response to Instantaneous Valve Closing*** Compute the wave speed and maximum pressure rise for instantaneous valve closing, with an initial velocity of 2.0 m/s, in a 4-in Schedule 40 steel pipe with elastic modulus $207 \times 10^9$ Pa. Repeat for a plastic pipe of the same dimensions, with $E = 1.4 \times 10^9$ Pa. The liquid is water with $\beta = 2.2 \times 10^9$ Pa and $\rho = 1000$ kg/m³.

For the steel pipe, $D = 102.3$ mm, $b = 6.02$ mm, and the wave speed is

$$a = \frac{\sqrt{\beta/\rho}}{\sqrt{1+(\beta/E)(D/b)}}$$

$$= \frac{\sqrt{2.2\times10^9/1000}}{\sqrt{1+(2.2\times10^9/207\times10^9)(102.3/6.02)}}$$

$$= 1365 \text{ m/s}$$

The maximum pressure rise $\Delta p = \rho a\, \Delta V = 1000 \times 1365 \times 2.0 = 2.73 \times 10^6$ Pa

For the plastic pipe,

$$a = \frac{\sqrt{2.2 \times 10^9/1000}}{\sqrt{1 + (2.2 \times 10^9/1.4 \times 10^9)(102.3/6.02)}}$$

$$= 282 \text{ m/s}$$

$$\Delta p = \rho a\, \Delta V = 1000 \times 282 \times 2.0 = 5.64 \times 10^5 \text{ Pa}$$

The maximum pressure surge is obtained when the valve closes in less time than the period $\tau$ required for the pressure wave to travel from the valve to the pipe inlet and back, a total distance of $2L$.

$$\tau = \frac{2L}{a} \tag{6-214}$$

The pressure surge will be reduced when the time of flow stoppage exceeds the pipe period $\tau$, due to cancellation of direct and reflected waves. D. J. Wood and S. E. Jones [*Proc. Am. Soc. Civ. Eng., J. Hydraul. Div.* **99:** 167–178 (1973)] present charts for estimates of water-hammer pressure for different valve closure modes. V. L. Wylie and E. B. Streeter [*Hydraulic Transients,* McGraw-Hill, New York, 1978] describe several solution methods for hydraulic transients, including the method of characteristics, which is well suited to computer methods for accurate solutions. A rough approximation for the peak pressure for cases where the valve closure time $t_c$ exceeds the pipe period $\tau$ is [R. L. Daugherty and J. B. Franzini, *Fluid Mechanics with Engineering Applications,* McGraw-Hill, New York, 1985]

$$\Delta p \approx \left(\frac{\tau}{t_c}\right) \rho a \Delta V \tag{6-215}$$

Successive reflections of the pressure wave between the pipe inlet and the closed valve result in alternating pressure increases and decreases, which are gradually attenuated by fluid friction and imperfect elasticity of the pipe. Periods of reduced pressure occur while the reflected pressure wave is traveling from inlet to valve. Degassing of the liquid may occur, as may vaporization if the pressure drops below the vapor pressure of the liquid. Gas and vapor bubbles decrease the wave velocity. Vaporization may lead to what is often called *liquid column separation;* subsequent collapse of the vapor pocket can result in pipe rupture.

In addition to water hammer induced by valve action, numerous other hydraulic transient flows are of interest, for example, those arising from starting or stopping of pumps; changes in power demand from turbines; reciprocating pumps; changing elevation of a reservoir; waves on a reservoir; turbine governor hunting; vibration of impellers or guide vanes in pumps, fans, or turbines; vibration of deformable parts such as valves; draft-tube instabilities due to vortexing; and unstable pump or fan characteristics [V. L. Wylie and E. B. Streeter, *Hydraulic Transients*, McGraw-Hill, New York, 1978]. Tube failure in heat exchangers is another cause of water hammer.

**Pulsating Flow** Reciprocating machinery (pumps and compressors) produces flow pulsations, which adversely affect flow meters and process control elements and can cause vibration and equipment failure, in addition to undesirable process results. Vibration and damage can result not only from the fundamental frequency of the pulse producer but also from higher harmonics. Multipiston double-acting units reduce vibrations. Pulsation dampeners are often added. Damping methods are described by M. W. Kellogg Co. [*Design of Piping Systems,* rev. 2d ed., Wiley, New York, 1965]. For liquid phase pulsation damping, gas-filled surge chambers, also known as accumulators, are commonly used; see Wylie and Streeter.

Commercial software programs are available for simulation of hydraulic transients. These may be used to analyze piping systems to reveal unsatisfactory behavior, and they allow the assessment of design changes such as increases in pipe wall thickness, changes in valve actuation, and addition of check valves, surge tanks, and pulsation dampeners.

**Cavitation** Loosely regarded as related to water hammer and hydraulic transients because it may cause similar vibration and equipment damage, *cavitation* is the collapse of vapor bubbles in flowing liquid. These bubbles may be formed where the local liquid pressure drops below the vapor pressure, or they may be injected into the liquid, as when steam is sparged into water. Local low-pressure zones may be produced by local velocity increases (in accordance with the Bernoulli equation) as in eddies or vortices, or near boundary contours; by rapid vibration of a boundary; by separation of liquid during water hammer; or by an overall reduction in static pressure, such as due to pressure drop in the suction line of a pump.

Collapse of vapor bubbles once they reach zones where the pressure exceeds the vapor pressure can cause objectionable noise and vibration and extensive erosion or pitting of the boundary materials. The critical cavitation number at inception of cavitation, denoted $\sigma_i$ is useful in correlating equipment performance data:

$$\sigma_i = \frac{p_i - p_v}{\rho V^2/2} \tag{6-216}$$

where $p_i$ = static pressure in undisturbed flow
$P_v$ = vapor pressure
$\rho$ = liquid density
$V$ = free-stream velocity of liquid

The value of the cavitation number for incipient cavitation for a specific piece of equipment is a characteristic of that equipment. Cavitation numbers for various head forms of cylinders, for disks, and for various hydrofoils are given by J. W. Holl and G. F. Wislicenus [*J. Basic Eng.* **83:** 385–398 (1961)] and for various surface irregularities by R. E. A. Arndt and A. T. Ippen [*J. Basic Eng.* **90:** 249–261 (1968)], J. W. Ball [*Proc. ASCE J. Constr. Div.* **89**(C02): 91–110 (1963)], and J. W. Holl [*J. Basic Eng.* **82:** 169–183 (1960)]. As a guide only, for blunt forms the cavitation number is generally in the range of 1 to 2.5, and for somewhat streamlined forms the cavitation number is in the range of 0.2 to 0.5. Critical cavitation numbers generally depend on a characteristic length dimension of the equipment in a way that has not been explained. This renders scale-up of cavitation data questionable.

Figure 6-51 [Y. Yan and R. B. Thorpe, *Int. J. Multiphase Flow* **16:** 1023–1045 (1990)] gives the critical cavitation number for flow through orifices. To use this cavitation number in Eq. (6-216), the pressure $p_i$ is the orifice back-pressure downstream of the vena contracta after full pressure recovery, and $V$ is the average velocity through the orifice. Figure 6-51 includes data from J. P. Tullis and R. Govindarajan [*ASCE J. Hydraul. Div.* **HY13:** 417–430 (1973)] modified to use the same cavitation number definition; their data also include critical cavitation numbers for 30.50- and 59.70-cm pipes. Very roughly, compared with the 15.40-cm pipe, the cavitation number is about 20 percent greater for the 30.50-cm-diameter pipe and about 40 percent greater for the 59.70-cm-diameter pipe. Inception of cavitation appears to be related to release of dissolved gas and not merely vaporization of the liquid. K. Takahashi et al. [CAV 2001: 4th Symp. on Cavitation, June 20–23, 2001, Cal Tech, Pasadena] present data showing reduction in cavitation intensity by using multihole instead of single-hole orifice plates. For further discussion of cavitation, see Eisenberg and M. P. Tulin in V. L. Streeter [*Handbook of Fluid Dynamics,* McGraw-Hill, New York, 1961, Sec. 12].

## TURBULENCE

Turbulent flow occurs when the Reynolds number exceeds a critical value above which laminar flow is unstable; the critical Reynolds number depends on the flow geometry. There is generally a transition regime between the critical Reynolds number and the Reynolds number at which the flow may be considered fully turbulent. In turbulent flow, variables such as velocity and pressure fluctuate chaotically; statistical methods are used to quantify turbulence.

**Time Averaging** For turbulent flows it is useful to define time-averaged and fluctuation values of flow variables. For example, the $x$-component velocity fluctuation $v_x'$ is the difference between the instantaneous velocity $v_x$ and the time-averaged velocity $\overline{v_x}$.

$$v_x'(x, y, z, t) = v_x(x, y, z, t) - \overline{v_x}(x, y, z) \tag{6-217}$$

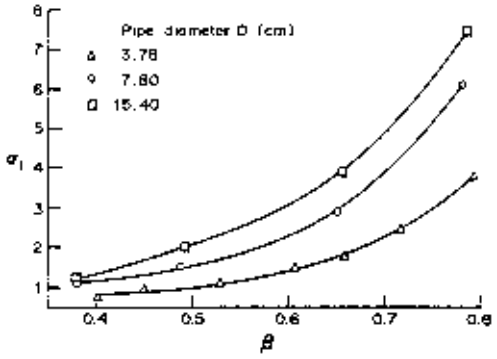

**FIG. 6-51** Critical cavitation number versus diameter ratio $\beta$. [Reprinted from Y. Yan and R. B. Thorpe, "Flow regime transitions due to cavitation in the flow through an orifice," *Int. J. Multiphase Flow,* **16,** 1023–1045. Copyright © 1990, with kind permission from Elsevier Science, Ltd., The Boulevard, Langford Lane, Kidlington OX5 1GB, United Kingdom.]

The instantaneous and fluctuating velocity components are, in general, functions of spatial position and of time $t$. The time-averaged velocity $\overline{v_x}$ is independent of time for a *stationary* flow. Nonstationary processes may be considered where averages are defined over time scales long compared to the time scale of the turbulent fluctuations, but short compared to the characteristic time scale of the flow. The time average over a time interval $2T$ centered at time $t$ of a turbulently fluctuating variable $\zeta(t)$ is defined as

$$\overline{\zeta(t)} = \frac{1}{2T}\int_{t-T}^{t+T} \zeta(\tau)\, d\tau \tag{6-218}$$

where $\tau$ = dummy integration variable. For stationary turbulence, $\overline{\zeta}$ does not vary with time.

The time average of a fluctuation is zero, $\overline{\zeta'} = \overline{\zeta - \overline{\zeta}} = 0$. Fluctuation magnitudes are quantified by root mean squares.

$$\tilde{v}_x' = \sqrt{\overline{(v_x')^2}} \tag{6-219}$$

In *isotropic* turbulence, statistical measures of fluctuations are equal in all directions.

$$\tilde{v}_x' = \tilde{v}_y' = \tilde{v}_z' \tag{6-220}$$

In *homogeneous* turbulence, turbulence properties are independent of spatial position. The *kinetic energy of turbulence* $k$ is given by

$$k = \frac{1}{2}\left(\tilde{v}_x'^2 + \tilde{v}_y'^2 + \tilde{v}_z'^2\right) \tag{6-221}$$

Velocity fluctuations ultimately dissipate their kinetic energy through viscous effects. Macroscopically, this energy dissipation requires pressure drop, or velocity decrease. The *energy dissipation rate* per unit mass is usually denoted $\varepsilon$. For steady flow in a pipe, the average energy dissipation rate per unit mass is given by

$$\varepsilon = \frac{2fV^3}{D} \tag{6-222}$$

where $f$ = Fanning friction factor
$D$ = pipe inside diameter
$V$ = average velocity

The continuity equation and the Navier-Stokes equation for incompressible flow may be time-averaged; this process is also known as *Reynolds averaging*. The time-averaged continuity equation for an incompressible fluid is similar to the instantaneous continuity equation (6-23), but with the time averaged velocity $\overline{\mathbf{v}}$ replacing the instantaneous velocity $\mathbf{v}$.

$$\nabla \cdot \overline{\mathbf{v}} = 0 \tag{6-223}$$

The Reynolds averaged Navier-Stokes (RANS) equation is similar to the instantaneous Navier-Stokes equation (6-27), except for the appearance of an additional term, the divergence of the *Reynolds stress*. This term arises from the averaging of the nonlinear $\mathbf{v}\cdot\nabla\mathbf{v}$ inertial term.

$$\rho\frac{D\overline{\mathbf{v}}}{Dt} = -\nabla\overline{p} + \mu\nabla^2\overline{\mathbf{v}} + \nabla\cdot\boldsymbol{\tau}^{(t)} + \rho\mathbf{g} \tag{6-224}$$

The Reynolds stress is

$$\boldsymbol{\tau}^{(t)} = -\rho\overline{\mathbf{v}'\mathbf{v}'} \tag{6-225}$$

Direct numerical simulation (DNS) under limited circumstances has been carried out to solve the unaveraged equations of motion and determine fluctuating velocity fields. Due to the extreme computational intensity, solutions to date have been limited to modest Reynolds numbers, generally in simple geometries, and sometimes with certain assumptions, such as periodicity in the flow direction. Since computational grids must be fine enough to resolve even the smallest eddies, the computational difficulty rapidly becomes prohibitive as the Reynolds number increases. Therefore, the solution of the equations of motion for turbulent flow is generally based on the time-averaged equations. This requires semiempirical models to express the Reynolds stresses in terms of time-averaged velocities. This is the *closure* problem of turbulence.

**Closure Models** A wide variety of closure models have been proposed. See S. B. Pope (*Turbulent Flows*, Cambridge University Press, Cambridge, UK, 2000) for descriptions of many of them. One class of closure model treats the Reynolds stress as analogous to the viscous stress, based on the proposition that turbulent eddy motion transports momentum in the same diffusive manner as the random motion of gas molecules. The Boussinesq approximation, simplified here for incompressible flow, introduces a scalar quantity called the *turbulent* or *eddy viscosity* $\mu_t$, in analogy to Eqs. (6-7) and (6-24).

$$\boldsymbol{\tau}^{(t)} = -\rho\overline{\mathbf{v}'\mathbf{v}'} = -\frac{2}{3}k\boldsymbol{\delta} + \mu_t[\nabla\overline{\mathbf{v}} + (\nabla\overline{\mathbf{v}})^T] \tag{6-226}$$

To solve the equations of motion using the Boussinesq approximation, it is necessary to provide equations for the single scalar unknowns $\mu_t$ and $k$, rather than the nine unknown tensor components $\tau_{ij}^{(t)}$. Solutions to the time-averaged equations for turbulent flow using Eq. (6-226) are not equivalent to Navier-Stokes solutions for laminar flow because $\mu_t$ is not a constant. The turbulent viscosity model is physically realistic under some circumstances, but not in others, such as those with large elongation rates in the mean velocity field [S. B. Pope, *Turbulent Flows*, Cambridge University Press, Cambridge, UK, 2000].

*Mixing length models* estimate the turbulent viscosity as the product of the square of a mixing length $\ell_M$ and a time-averaged velocity gradient. The mixing length is geometry-dependent and must be specified to complete a model, rendering the model unsuitable for general predictive use. In boundary layer flows, the mixing length is assumed to be proportional to distance $y$ from the wall, and $\left|\partial\overline{v_x}/\partial y\right|$ is chosen for the velocity gradient. The universal turbulent velocity profile near the pipe wall presented in the preceding subsection Incompressible Flow in Pipes and Channels may be developed using the Prandtl mixing length approximation for the eddy viscosity,

$$\mu_t = \rho l_P^2\left|\frac{d\overline{v_x}}{dy}\right| \tag{6-227}$$

where $l_P$ is the Prandtl mixing length. The turbulent core of the universal velocity profile is obtained by assuming that the mixing length is proportional to the distance from the wall. The proportionality constant is one of two constants adjusted to fit experimental data.

The Prandtl mixing length concept is useful for shear flows parallel to walls, but is inadequate for multidimensional flows. A more advanced semiempirical model commonly used in numerical computations, and found in most commercial software for computational fluid dynamics (CFD; see the following subsection), is the $k$–$\varepsilon$ model described by B. Launder and D. Spalding [*Lectures in Mathematical Models of Turbulence,* Academic, London, 1972]. In this model the eddy viscosity is assumed proportional to the ratio $k^2/\varepsilon$.

$$\mu_t = \rho C_\mu\frac{k^2}{\varepsilon} \tag{6-228}$$

where the value $C_\mu = 0.09$ is normally used. Semiempirical partial differential conservation equations for $k$ and $\varepsilon$ derived from the Navier-Stokes equations with simplifying closure assumptions are coupled with the equations of continuity and momentum. They may be written as

$$\frac{\partial}{\partial t}(\rho k) + \nabla\cdot(\rho\overline{\mathbf{v}}k) = \nabla\cdot\left(\frac{\mu_t}{\sigma_k}\nabla k\right) + \mu_t[\nabla\overline{\mathbf{v}} + (\nabla\overline{\mathbf{v}})^T]\,\nabla\overline{\mathbf{v}} - \rho\varepsilon \tag{6-229}$$

$$\frac{\partial}{\partial t}(\rho\varepsilon) + \nabla\cdot(\rho\overline{\mathbf{v}}\varepsilon) = \nabla\cdot\left(\frac{\mu_t}{\sigma_\varepsilon}\nabla\varepsilon\right) + C_{1\varepsilon}\frac{\varepsilon\mu_t}{k}[\nabla\overline{\mathbf{v}} + (\nabla\overline{\mathbf{v}})^T]\,\nabla\overline{\mathbf{v}} - C_{2\varepsilon}\frac{\rho\varepsilon^2}{k} \tag{6-230}$$

The values for the empirical constants $C_{1\varepsilon} = 1.44$, $C_{2\varepsilon} = 1.92$, $\sigma_k = 1.0$, and $\sigma_\varepsilon = 1.3$ are widely accepted [B. Launder and D. Spaulding, *The Numerical Computation of Turbulent Flows,* Imperial Coll. Sci. Tech. London, NTIS N74-12066 (1973)]. The $k$–$\varepsilon$ model has proved reasonably accurate for many flows without highly curved streamlines or significant swirl. It usually underestimates flow separation and overestimates turbulence production by normal straining. The $k$–$\varepsilon$ model is suitable for flows with high Reynolds numbers. See C. Virendra et al. [*AIAA J.* **23:** 1308–1319 (1984)] for a review of low Reynolds number $k$–$\varepsilon$ models. Several other models based on turbulent viscosity exist. Some are two-equation model variants of the $k$–$\varepsilon$ model, such as the $k$–$\omega$ model, where $\omega = \varepsilon/k$. A variant of the mixing length model is one using $k^{1/2}$ as a characteristic velocity so that $\mu_t \propto \rho k^{1/2}\ell_M$.

A second class of RANS closure models is based on solution of model transport equations for each of the independent components of $\boldsymbol{\tau}^{(t)}$ (due to symmetry, there are six independent components). One additional transport equation, usually for the dissipation rate $\varepsilon$, must also be solved. These models are computationally more intensive than turbulent viscosity-based models, but they are more accurate. Perhaps confusingly, these models are called Reynolds stress models, even though all RANS closure models are models

for the Reynolds stress. A widely cited example is that of B. Launder et al. [*J. Fluid Mech.* **68:** 537–566 (1975)]. S. B. Pope [*Turbulent Flows*, Cambridge University Press, Cambridge, UK, 2000] may be consulted for a thorough discussion of Reynolds stress models.

A third class of models is *large eddy simulation* (LES). In LES, filtered versions of the equations of motion are derived, where the instantaneous velocity is decomposed into resolved (large-scale) and modeled (small-scale) motions. Lower-frequency eddies, with scales larger than the grid spacing, are resolved, while higher-frequency eddies, the subgrid fluctuations, are filtered out. Closure models are required for the subgrid-scale Reynolds stress. The Smagorinsky model, a one-equation mixing length model, is used in most commercial CFD (see Computational Fluid Dynamics below) codes that offer LES options and is also used in many academic and research CFD codes. See D. C. Wilcox [*Turbulence Modeling for CFD,* 2d ed., DCW Industries, La Cañada, Calif., 1998]. LES models are more accurate and more computationally intensive than Reynolds stress models. While they are not nearly as computationally expensive as direct numerical simulation, it is generally believed that highly accurate LES predictions of mean flow fields and large-scale motions can be obtained with practical computational grids.

A fourth class of models is based on solving transport equations, derived from the Navier-Stokes equation, for probability density functions. The PDF-based methods require solution of stochastic differential equations and generally are based on particle tracking methods. Closure models are not needed for the convective momentum transport that leads to the Reynolds stress in the RANS equation [S. B. Pope, *Turbulent Flows*, Cambridge University Press, Cambridge, UK, 2000].

**Eddy Spectrum** The energy that produces and sustains turbulence is extracted from velocity gradients in the mean flow, principally through vortex stretching. At Reynolds numbers well above the critical value there is a wide spectrum of eddy sizes, often described as a cascade of energy from the largest down to the smallest eddies. The largest eddies are of the order of the equipment size. The smallest are those for which viscous and inertial forces associated with the eddy velocity fluctuations are of the same order, so that turbulent fluctuations are rapidly damped out by viscous effects at smaller length scales. A distribution function may be plotted showing the distribution of kinetic energy with respect to eddy size. The peak of the distribution, that is, the eddy size containing the most kinetic energy, is much larger than the smallest eddies when the Reynolds number is large. The small eddies contain relatively little kinetic energy, but are responsible for most of the viscous dissipation. Large eddies, which extract energy from the mean flow velocity gradients, are generally anisotropic. At smaller length scales, the directionality of the mean flow exerts less influence, and *local isotropy* is approached. The range of eddy scales for which local isotropy holds is called the *equilibrium range.*

J. T. Davies [*Turbulence Phenomena,* Academic, New York, 1972] presents a good discussion of the spectrum of eddy lengths for well-developed isotropic turbulence. The smallest eddies, usually called *Kolmogorov eddies*, have a characteristic velocity fluctuation $u_K$ given by

$$u_K = (\nu\varepsilon)^{1/4} \tag{6-231}$$

where $\nu$ = kinematic viscosity and $\varepsilon$ = energy dissipation per unit mass [A. N. Kolmogorov, *Compt. Rend. Acad. Sci. URSS* **30:** 301; **32:** 16 (1941)]. The size of the Kolmogorov eddy scale is

$$l_K = (\nu^3/\varepsilon)^{1/4} \tag{6-232}$$

The Reynolds number for the Kolmogorov eddy, $\mathrm{Re}_K = l_K u_K/\nu$, is equal to unity. In the equilibrium range, which exists for well-developed turbulence and extends from the medium eddy sizes down to the smallest, the energy dissipation at the smaller length scales is supplied by turbulent energy drawn from the bulk flow and passed down the spectrum of eddy lengths according to the scaling rule

$$\varepsilon = \frac{u^3}{l} \tag{6-233}$$

For the energy-containing, eddy size

$$\varepsilon = \frac{u_e^3}{l_e} \tag{6-234}$$

For turbulent pipe flow, the friction velocity $\mu^* = \sqrt{\tau_w/\rho}$ used earlier in describing the universal turbulent velocity profile may be used as an estimate for $u_e$. Together with the Blasius equation for the friction factor from which $\varepsilon$ may be obtained, Eq. (6-222), this provides an estimate for the energy-containing eddy size in turbulent pipe flow:

$$l_e = 0.05D\,\mathrm{Re}^{-1/8} \tag{6-235}$$

where $D$ = pipe diameter and Re = pipe Reynolds number. Similarly, the Kolmogorov eddy size is

$$l_K = 4D\,\mathrm{Re}^{-0.78} \tag{6-236}$$

Most of the energy dissipation occurs on a length scale about 5 times the Kolmogorov eddy size.

The eddy spectrum is normally described using Fourier transform methods. The spectrum $E(\kappa)$ gives the turbulent kinetic energy contained in eddies of wave number between $\kappa$ and $\kappa + d\kappa$, so that $K = \int_0^\infty E(\kappa)\,d\kappa$. The portion of the equilibrium range excluding the smallest eddies, those which are affected by dissipation, is the *inertial subrange.* The Kolmogorov law gives $E(\kappa) \propto \kappa^{-5/3}$ in the inertial subrange.

Texts for further reading on turbulent flow include S. B. Pope [*Turbulent Flows*, Cambridge University Press, Cambridge, UK, 2000], J. T. Davies [*Turbulence Phenomena,* Academic, New York, 1972], J. O. Hinze [*Turbulence,* McGraw-Hill, New York, 1975], H. Tennekes and J. L. Lumley [*A First Course in Turbulence,* MIT Press, Cambridge, Mass., 1972], and U. Frisch [*Turbulence*, Cambridge University Press, Cambridge, UK, 1995].

## COMPUTATIONAL FLUID DYNAMICS

Computational fluid dynamics (CFD) emerged in the 1980s as a significant tool for fluid dynamics in both research and practice, enabled by rapid development in computer hardware and software. Commercial CFD software is widely available. Computational fluid dynamics normally refers to the numerical solution of the equations of continuity and momentum (e.g., Navier-Stokes equations) along with additional conservation equations for energy and material species in order to solve problems of nonisothermal flow, mixing, and chemical reaction.

Textbooks include C. A. J. Fletcher [*Computational Techniques for Fluid Dynamics,* vol. 1: *Fundamental and General Techniques,* and vol. 2: *Specific Techniques for Different Flow Categories,* Springer-Verlag, Berlin, 1988], C. Hirsch [*Numerical Computation of Internal and External Flows,* vol. 1: *Fundamentals of Numerical Discretization,* and vol. 2: *Computational Methods for Inviscid and Viscous Flows,* Wiley, New York, 1988], R. Peyret and T. D. Taylor [*Computational Methods for Fluid Flow,* Springer-Verlag, Berlin, 1990], C. Canuto et al. [*Spectral Methods in Fluid Dynamics,* Springer-Verlag, Berlin, 1988], R. H. Pletcher et al. [*Computational Fluid Mechanics and Heat Transfer,* 3d ed., CRC Press, Boca Raton, FL, 2013], and Patankar [*Numerical Heat Transfer and Fluid Flow,* Hemisphere, Washington, D.C., 1980].

A variety of numerical methods has been employed, but three basic steps are common.

1. *Subdivision or discretization of the flow domain into cells or elements.* Discretization produces a *mesh* and a set of *nodes* at which the flow variables are calculated. The equations of motion are solved approximately on a domain defined by the grid. The grid must be sufficiently refined to resolve flow features and to accurately fit the boundaries.

2. *Discretization of the governing equations.* In this step, the spatial partial derivatives are replaced by algebraic approximations written in terms of the nodal values of the dependent variables. Among the numerous spatial discretization methods, *finite difference, finite volume,* and *finite element* methods are the most common. The *finite difference* method estimates spatial derivatives in terms of the nodal values and spacing between nodes. The governing equations are then written in terms of the nodal unknowns at each interior node. *Finite volume* methods, related to finite difference methods, may be derived by a volume integration of the equations of motion, with application of the divergence theorem, reducing by one the order of the differential equations. Equivalently, macroscopic balance equations are written on each cell. *Finite element* methods are weighted residual techniques in which the unknown dependent variables are expressed in terms of *basis functions* interpolating among the nodal values. The basis functions are substituted into the equations of motion, resulting in error residuals which are multiplied by the weighting functions, integrated over the control volume, and set to zero to produce algebraic equations in terms of the nodal unknowns. Selection of the weighting functions defines the various finite element methods. For example, Galerkin's method uses the nodal interpolation basis functions as weighting functions. Each approach also has its own method for implementing *boundary conditions.* The end result after discretization of the equations and application of the boundary conditions for a steady flow is a set of algebraic equations for the nodal unknown variables. Discretization in time is also required for the time derivative terms in unsteady flow. The discretized equations represent an approximation of the exact equations, and their solution gives an approximation for the flow variables. The accuracy of the solution improves as the grid is *refined,* that is, as the number of nodal points is increased.

3. *Solution of the discretized equations.* Creeping flows with constant viscosity yield a linear matrix equation. Both direct and iterative solvers have been used. For most flows, the nonlinear inertial terms in the momentum equation are important, and the algebraic discretized equations are therefore nonlinear. Solution yields the nodal values of the unknowns. Various implicit and explicit methods for time integration have been employed.

A CFD method called the *lattice Boltzmann method* (LBM) models the fluid as a set of particles moving with discrete velocities on a discrete grid or lattice, rather than using discretization of the governing continuum partial differential equations. Reviews of the LBM include those by S. Chen and G. D. Doolen [*Ann. Rev. Fluid Mech.* **30:** 329 (1998)] and C. K. Aiden and J. R. Clausen [*Ann. Rev. Fluid Mech.* **42:** 439 (2010)]. Lattice Boltzmann approximations can be constructed that give the same macroscopic behavior as the Navier-Stokes equations. The method is currently used mainly in academic and research codes, rather than in general-purpose commercial CFD codes. There appear to be significant computational advantages to the lattice Boltzmann method, particularly with respect to parallel processing. For turbulent flows, direct numerical simulation, as well as turbulence models analogous to those described in the Turbulence section above, can be applied using LBM. This includes both unfiltered and filtered (subgrid scale) turbulence models, the latter described by S. Hou et al. [*Fields Institute Comm.* **6:** 151 (1996)]. Multiphase flow, heat transfer, species diffusion, and chemical reaction have been solved. LBM methods for multifluid flows and for flows with particulates are described by X. Shan and H. Chen [*Phys. Rev. E* **47:** 1815 (1993)] and Feng and Michaelides [*J. Comput. Phys.* **195:** 602–628 (2004)], respectively.

CFD solutions, especially for complex three-dimensional flows, generate very large quantities of solution data. Computer graphics have greatly improved the ability to examine CFD solutions and visualize flow.

CFD methods are used for incompressible and compressible, creeping, laminar and turbulent, newtonian and nonnewtonian, and isothermal and nonisothermal flows. Chemically reacting flows, particularly in the field of combustion, have been simulated. Solution accuracy must be considered from several perspectives. These include convergence of the algorithms for solving the nonlinear discretized equations and convergence with respect to refinement of the mesh so that the discretized equations better approximate the exact equations and, in some cases, so that the mesh more accurately fits the true geometry. The possibility that steady-state solutions are unstable should be considered. In addition to numerical sources of error, modeling errors are introduced in turbulent flow, where closure models are used to solve time-averaged equations of motion, as discussed previously. Most commercial CFD codes include the $k$–$\varepsilon$ turbulence model, and often several other models such as the ones described previously under subsection Turbulence are included. Large eddy simulation (LES) methods for turbulent flow, described previously, are available in commercial CFD codes. Significant solution error is known to result in some problems from inadequacy of the turbulence model. Closure models for nonlinear chemical reaction source terms may also contribute to inaccuracy.

In its general sense, multiphase flow is not currently solvable by computational fluid dynamics. However, in certain cases reasonable solutions are possible. These include well-separated flows where the phases are confined to relatively well-defined regions separated by one or a few interfaces and flows in which a second phase appears as discrete particles of known size and shape whose motion may be approximately computed with drag coefficient formulations, or rigorously computed with refined meshes applying boundary conditions at the particle surface. *Two-fluid modeling,* in which the phases are treated as overlapping continua, with each phase occupying a volume fraction that is a continuous function of position (and time), is a useful approximation available in commercial software. See S. E. Elghobashi and T. W. Abou-Arab [*J. Physics Fluids* **26:** 931–938 (1983)] for a $k$–$\varepsilon$ model for two-fluid systems.

## DIMENSIONLESS GROUPS

For purposes of data correlation, model studies, and scale-up, it is useful to arrange variables into dimensionless groups. Table 6-9 lists many of the dimensionless groups commonly found in fluid mechanics problems, along with their physical interpretations and areas of application. More extensive tabulations may be found in J. P. Catchpole and G. Fulford [*Ind. Eng. Chem.* **58**(3): 46–60 (1966)] and G. Fulford and J. P. Catchpole [*Ind. Eng. Chem.* **60**(3): 71–78 (1968)].

**TABLE 6-9 Dimensionless Groups and Their Significance**

| Name | Symbol | Formula | Physical interpretation | Comments |
|---|---|---|---|---|
| Archimedes number | Ar | $\frac{gL^3(\rho_p-\rho)\rho}{\mu^2}$ | $\frac{\text{inertial forces} \times \text{buoyancy force}}{(\text{viscous forces})^2}$ | Particle settling |
| Bingham number | Bm | $\frac{\tau_y L}{\mu_\infty V}$ | $\frac{\text{yield stress}}{\text{viscous stress}}$ | Flow of Bingham plastics = yield number $Y$ |
| Bingham Reynolds number | $\text{Re}_B$ | $\frac{LV\rho}{\mu_\infty}$ | $\frac{\text{inertial forces}}{\text{viscous forces}}$ | Flow of Bingham plastics |
| Blake number | B | $\frac{V\rho}{\mu(1-\epsilon)_s}$ | $\frac{\text{inertial forces}}{\text{viscous forces}}$ | Beds of solids |
| Bond number | Bo | $\frac{(\rho_L-\rho_G)L^2 g}{\sigma}$ | $\frac{\text{gravitational force}}{\text{surface-tension force}}$ | Atomization = Eotvos number Eo |
| Capillary number | Ca | $\frac{\mu V}{\sigma}$ | $\frac{\text{viscous force}}{\text{surface-tension force}}$ | Two-phase flows, free surface flows |
| Cauchy number | C | $\frac{\rho V^2}{\beta}$ | $\frac{\text{inertial force}}{\text{compressibility force}}$ | Compressible flow, hydraulic transients |
| Cavitation number | $\sigma$ | $\frac{p-p_v}{\rho V^2/2}$ | $\frac{\text{excess pressure above vapor pressure}}{\text{velocity head}}$ | Cavitation |
| Dean number | De | $\frac{\text{Re}}{(Dc/D)^{1/2}}$ | $\text{Reynolds number} \times \frac{\text{inertial force}}{\text{centrifugal force}}$ | Flow in curved channels |
| Deborah number | De | $\lambda\omega$ | $\frac{\text{fluid relaxation time}}{\text{flow characteristic time}}$ | Viscoelastic flow |
| Drag coefficient | $C_D$ | $\frac{F_D}{A\rho V^2/2}$ | $\frac{\text{drag force}}{\text{projected area} \times \text{velocity head}}$ | Flow around objects, particle settling |
| Elasticity number | El | $\frac{\lambda\mu}{\rho L^2}$ | $\frac{\text{elastic force}}{\text{inertial force}}$ | Viscoelastic flow |
| Euler number | Eu | $\frac{\Delta p}{\rho V^2}$ | $\frac{\text{frictional pressure loss}}{2 \times \text{velocity head}}$ | Fluid friction in conduits |
| Fanning friction factor | $f$ | $\frac{D\Delta p}{2\rho V^2 L}=\frac{2\tau_w}{\rho V^2}$ | $\frac{\text{wall shear stress}}{\text{velocity head}}$ | Fluid friction in conduits Darcy |

## DRAG COEFFICIENT

When relative motion exists between a particle and a surrounding fluid, the fluid will exert a drag force upon the particle. In steady flow, the drag force is

$$F_D = \frac{C_D A_P \rho u^2}{2} \tag{6-237}$$

where $F_D$ = drag force
$C_D$ = drag coefficient
$A_P$ = projected particle area in direction of motion
$\rho$ = density of surrounding fluid
$u$ = relative velocity between particle and fluid

The drag force is exerted in a direction parallel to the relative velocity. Equation (6-237) defines the *drag coefficient.* For some solid bodies, such as aerofoils, a lift force component perpendicular to the velocity is also exerted. For free-falling particles, lift forces are generally unimportant. However, even spherical particles experience lift forces in shear flows near solid surfaces.

## TERMINAL VELOCITY

A particle falling under the action of gravity will accelerate until the drag force balances gravitational force, after which it falls at its *terminal* or *free-settling velocity* $u_t$, given by

$$u_t = \frac{\sqrt{2gm_p(\rho_p - \rho)}}{\rho \rho_p A_P C_D} \tag{6-238}$$

where $g$ = acceleration of gravity
$m_p$ = particle mass
$\rho_p$ = particle density

and the remaining symbols are as previously defined.

Settling particles may undergo fluctuating motions owing to vortex shedding, among other factors. Oscillation is enhanced with increasing separation between the mass and geometric centers of the particle. Variations in velocity are usually less than 10 percent. The drag force on a particle fixed in space with fluid moving is somewhat lower than the drag force on an oscillating freely settling particle in a stationary fluid at the same relative velocity.

**Spherical Particles** For spherical particles of diameter $d_p$, Eq. (6-238) becomes

$$u_t = \frac{\sqrt{4gd_p(\rho_p - \rho)}}{3\rho C_D} \tag{6-239}$$

The drag coefficient for rigid spherical particles is a function of particle Reynolds number $\mathrm{Re}_p = d_p \rho u/\mu$ where $\mu$ = fluid viscosity, as shown in Fig. 6-52. At low Reynolds number, *Stokes' law* gives

$$C_D = \frac{24}{\mathrm{Re}_p} \qquad \mathrm{Re}_p < 0.1 \tag{6-240}$$

which may also be written

$$F_D = 3\pi\mu u d_p \qquad \mathrm{Re}_p < 0.1 \tag{6-241}$$

and gives for the terminal settling velocity

$$u_t = \frac{gd_p^2(\rho_p - \rho)}{18\mu} \qquad \mathrm{Re}_p < 0.1 \tag{6-242}$$

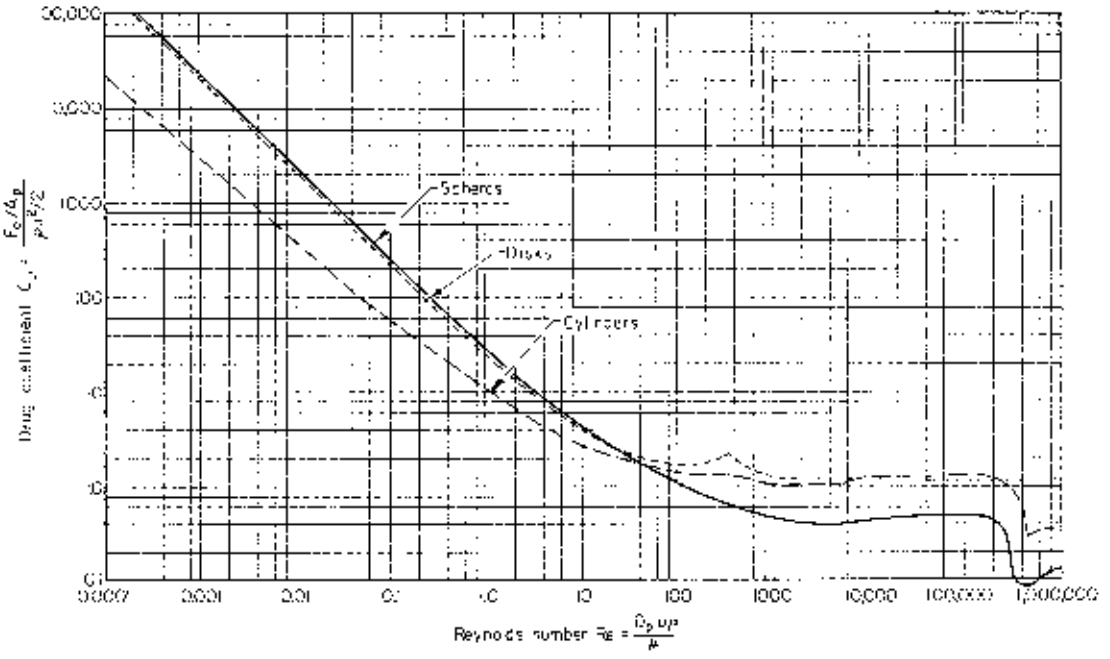

**FIG. 6-52** Drag coefficients for spheres, disks, and cylinders: $A_p$ = area of particle projected on a plane normal to direction of motion; $C$ = overall drag coefficient, dimensionless; $D_p$ = diameter of particle; $F_d$ = drag or resistance to motion of body in fluid; Re = Reynolds number, dimensionless; $u$ = relative velocity between particle and main body of fluid; $\mu$ = fluid viscosity; and $\rho$ = fluid density. [From C. E. Lapple and C. B. Shepherd, *Ind. Eng. Chem.*, **32,** 605 (1940).]

In the *intermediate regime* ($0.1 < \mathrm{Re}_p < 1000$), the drag coefficient may be estimated within 6 percent by

$$C_D = \left(\frac{24}{\mathrm{Re}_p}\right)\left(1+0.14\,\mathrm{Re}_p^{0.70}\right) \qquad 0.1 < \mathrm{Re}_p < 1000 \tag{6-243}$$

In *Newton's law* regime, which covers the range $1000 < \mathrm{Re}_p < 350{,}000$, $C_D = 0.445$, within 13 percent. In this region, Eq. (6-239) becomes

$$u_t = 1.73\sqrt{\frac{gd_p(\rho_p-\rho)}{\rho}} \qquad 1000 < \mathrm{Re}_p < 350{,}000 \tag{6-244}$$

Between about $\mathrm{Re}_p = 350{,}000$ and $1 \times 10^6$, the drag coefficient drops dramatically in a *drag crisis* owing to the transition to turbulent flow in the boundary layer around the particle, which delays aft separation, resulting in a smaller wake and less drag. Beyond $\mathrm{Re}_p = 1 \times 10^6$, the drag coefficient may be estimated from [R. Clift, J. R. Grace, and M. E. Weber, *Bubbles, Drops and Particles,* Academic, New York, 1978]

$$C_D = 0.19 - \frac{8\times10^4}{\mathrm{Re}_p} \qquad \mathrm{Re}_p > 1\times10^6 \tag{6-245}$$

Drag coefficients may be affected by turbulence in the free-stream flow; the drag crisis occurs at lower Reynolds numbers when the free stream is turbulent. L. B. Torobin and W. H. Guvin [*AIChE J.* **7:** 615–619 (1961)] found that the drag crisis Reynolds number decreases with increasing free-stream turbulence, reaching a value of 400 when the relative turbulence intensity, defined as $\sqrt{u'}/\overline{U}_R$, is 0.4. Here $\sqrt{u'}$ is the rms fluctuating velocity and $\overline{U}_R$ is the time-averaged relative velocity between the particle and the fluid.

For computing the terminal settling velocity, correlations for drag coefficient as a function of Archimedes number

$$\mathrm{Ar} = \frac{gd_p^3(\rho_\rho-\rho)\rho}{\mu^2} \tag{6-246}$$

may be more convenient than $C_D$–$\mathrm{Re}_p$ correlations, because the latter are implicit in terminal velocity, and the settling regime is unknown. D. G. Karamanev [*Chem. Eng. Comm.* **147:** 75 (1996)] provides a correlation for drag coefficient for settling solid spheres in terms of Ar.

$$C_D = \frac{432}{\mathrm{Ar}}(1+0.0470\,\mathrm{Ar}^{2/3}) + \frac{0.517}{1+154\,\mathrm{Ar}^{-1/3}} \tag{6-247}$$

This equation reduces to Stokes' law $C_D = 24/\mathrm{Re}_p$ in the limit $\mathrm{Ar} \to 0$ and is a fit to data up to about $\mathrm{Ar} = 2 \times 10^{10}$, where it gives $C_D = 0.50$, slightly greater than Newton's law value above. For rising light spheres, which exhibit more energy dissipating lateral motion than do falling dense spheres, Karamanev found that Eq. (6-247) is followed up to Ar = 13,000 and that for Ar > 13,000, the drag coefficient is $C_D = 0.95$.

For particles settling in *nonnewtonian* fluids, correlations are given by Dallon and Christiansen [Preprint 24C, *Symposium on Selected Papers,* part III, 61st Ann. Mtg. AIChE, Los Angeles, Dec. 1–5, 1968] for spheres settling in shear-thinning liquids, and by S. Ito and T. Kajiuchi [*J. Chem. Eng. Japan,* **2**(1): 19–24 (1969)] and H. Pazwash and J. M. Robertson [*J. Hydraul. Res.* **13:** 35–55 (1975)] for spheres settling in Bingham plastics. A. N. Beris et al. [*J. Fluid Mech.* **158:** 219–244 (1985)] present a finite element calculation for creeping motion of a sphere through a Bingham plastic.

**Nonspherical Rigid Particles** The drag on a nonspherical particle depends upon its shape and orientation with respect to the direction of motion. The orientation in free fall as a function of Reynolds number is given in Table 6-10.

The drag coefficients for *disks* (flat side perpendicular to the direction of motion) and for *cylinders* (infinite length with axis perpendicular to the direction of motion) are given in Fig. 6-52 as a function of Reynolds number.

**TABLE 6-10 Free-Fall Orientation of Particles**

| Reynolds number* | Orientation |
|---|---|
| 0.1–5.5 | All orientations are stable when there are three or more perpendicular axes of symmetry. |
| 5.5–200 | Stable in position of maximum drag. |
| 200–500 | Unpredictable. Disks and plates tend to wobble, while fuller bluff bodies tend to rotate. |
| 500–200,000 | Rotation about axis of least inertia, frequently coupled with spiral translation |

*Based on diameter of a sphere having the same surface area as the particle.
SOURCE: From Becker, *Can. J. Chem. Eng.* **37:** 85–91 (1959).

The effect of length-to-diameter ratio for cylinders in Newton's law region is reported by J. G. Knudsen and D. L. Katz [*Fluid Mechanics and Heat Transfer,* McGraw-Hill, New York, 1958].

E. S. Pettyjohn and E. B. Christiansen [*Chem. Eng. Prog.* **44:** 157–172 (1948)] present correlations for the effect of particle shape on free-settling velocities of *isometric particles.* For Re < 0.05, the terminal or free-settling velocity is given by

$$u_t = K_1\frac{gd_s^2(\rho_p-\rho)}{18\mu} \tag{6-248}$$

$$K_1 = 0.843\log\left(\frac{\psi}{0.065}\right) \tag{6-249}$$

where $\psi$ = sphericity, the surface area of a sphere having the same volume as the particle, divided by the actual surface area of the particle; $d_s$ = equivalent diameter, equal to the diameter of the equivalent sphere having the same volume as the particle; and other variables are as previously defined.

In *Newton's law region,* the terminal velocity is given by

$$u_t = \sqrt{\frac{4d_s(\rho_p-\rho)g}{3K_3\rho}} \tag{6-250}$$

$$K_3 = 5.31 - 4.88\psi \tag{6-251}$$

Equations (6-248) to (6-251) are based on experiments on cube-octahedrons, octahedrons, cubes, and tetrahedrons for which the sphericity $\psi$ ranges from 0.906 to 0.670, respectively. See also R. Clift, J. R. Grace, and M. E. Weber, *Bubbles, Drops and Particles,* Academic, New York, 1978. A graph of drag coefficient versus Reynolds number with $\psi$ as a parameter may be found in Brown et al. [*Unit Operations,* Wiley, New York, 1950] and in G. W. Govier and K. Aziz [*The Flow of Complex Mixtures in Pipes,* Krieger, Huntington, N.Y., 1977].

For particles with $\psi < 0.67$, the correlations of Becker [*Can. J. Chem. Eng.* **37:** 85–91 (1959)] should be used. Reference to this paper is also recommended for *intermediate region* flow. Settling characteristics of nonspherical particles are discussed in chaps. 4 and 6 of R. Clift, J. R. Grace, and M. E. Weber, *Bubbles, Drops and Particles,* Academic, New York, 1978.

The terminal velocity of *axisymmetric particles in axial motion* can be computed from Bowen and Masliyah [*Can. J. Chem. Eng.* **51:** 8–15 (1973)] for low–Reynolds number motion:

$$u_t = \frac{V'}{K_2}\frac{gD_s^2(\rho_p-\rho)}{18\mu} \tag{6-252}$$

$$K_2 = 0.244 + 1.035\Sigma - 0.712\Sigma^2 + 0.441\Sigma^3 \tag{6-253}$$

where $D_s$ = diameter of sphere with perimeter equal to maximum particle projected perimeter
$V'$ = ratio of particle volume to volume of sphere with diameter $D_s$
$\Sigma$ = ratio of surface area of particle to surface area of a sphere with diameter $D_s$

and other variables are as defined previously.

**Hindered Settling** When particle concentration increases, particle settling velocities decrease because of hydrodynamic interaction between particles and the upward motion of displaced liquid. The suspension viscosity increases. Hindered settling is normally encountered in sedimentation and transport of concentrated slurries. Below 0.1 percent volumetric particle concentration, there is less than 1 percent reduction in settling velocity. Several expressions have been given to estimate the effect of particle volume fraction on settling velocity. Maude and Whitmore [*Br. J. Appl. Phys.* **9:** 477–482 (1958)] give for uniformly sized spheres

$$u_t = u_{t0}(1-c)^n \tag{6-254}$$

where $u_t$ = terminal settling velocity
$u_{t0}$ = terminal velocity of a single sphere (infinite dilution)
$c$ = volume fraction solid in the suspension
$n$ = function of Reynolds number $\mathrm{Re}_p = d_p u_{t0}\rho/\mu$ as given in Fig. 6-53

In Stokes' law region ($\mathrm{Re}_p < 0.3$) $n = 4.65$ and in Newton's law region ($\mathrm{Re}_p > 1000$) $n = 2.33$. Equation (6-254) may be applied to particles of any size in a polydisperse system, provided the volume fraction corresponding to all the particles is used in computing terminal velocity [Richardson and Shabi, *Trans. Inst. Chem. Eng.* (*London*) **38:** 33–42 (1960)]. The concentration effect is greater for nonspherical and angular particles than for spherical particles [Steinour, *Ind. Eng. Chem.* **36:** 840–847 (1944)]. Theoretical developments for low–Reynolds number flow assemblages of spheres are given

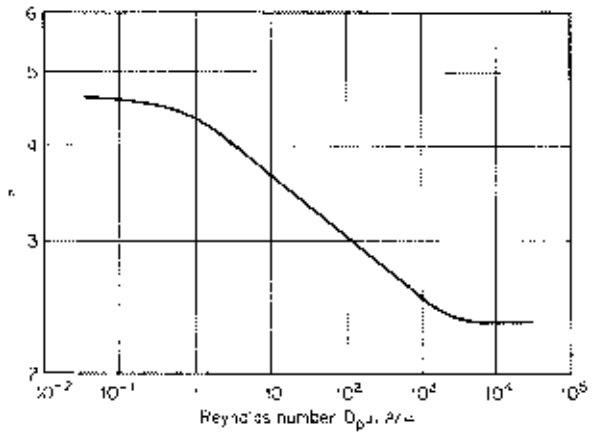

**FIG. 6-53** Values of exponent $n$ for use in Eq. (6-254). [From A. D. Maude and R. L. Whitmore, *Br. J. Appl. Phys.*, **9,** 481 (1958). *Courtesy of the Institute of Physics and the Physical Society.*]

by Happel and Brenner [*Low Reynolds Number Hydrodynamics,* Prentice-Hall, Englewood Cliffs, N.J., 1965] and Famularo and Happel [*AIChE J.* **11:** 981 (1965)] leading to an equation of the form

$$u_t = \frac{u_{t0}}{1+\gamma c^{1/3}} \tag{6-255}$$

where $\gamma$ is about 1.3. As particle concentration increases, resulting in interparticle contact, hindered settling velocities are difficult to predict. Thomas [*AIChE J.* **9:** 310 (1963)] provides an empirical expression reported to be valid over the range $0.08 < u_t/u_{t0} < 1$:

$$\ln\left(\frac{u_t}{u_{t0}}\right) = -5.9c \tag{6-256}$$

**Time-Dependent Motion** The time-dependent motion of particles is computed by application of Newton's second law, equating the rate of change of particle momentum to the net force acting on the particle. Rotation of particles may also be computed from the net torque. For large particles moving through low-density gases, it is usually sufficient to compute the force due to fluid drag from the relative velocity and the drag coefficient computed for steady flow conditions. For two- and three-dimensional problems, the velocity appearing in the particle Reynolds number and the drag coefficient is the amplitude of the relative velocity. The drag force, not the relative velocity, is resolved into vector components to compute the particle acceleration components. R. Clift, J. R. Grace, and M. E. Weber [*Bubbles, Drops and Particles,* Academic, New York, 1978] discuss the complexities that arise in the computation of transient drag forces on particles when the transient nature of the flow is important. Analytical solutions for the case of a single particle in creeping flow ($\mathrm{Re}_p = 0$) are available. For example, the creeping motion of a spherical particle released from rest in a stagnant fluid is described by

$$\rho V\frac{dU}{dt} = g(\rho_p-\rho)V - 3\pi\mu d_p U - \frac{\rho}{2}V\frac{dU}{dt} - \left(\frac{3}{2}\right)d_p^2\sqrt{\pi\rho\mu}\int_o^t \frac{(dU/dt)_{t=s}\,ds}{\sqrt{t-s}} \tag{6-257}$$

Here, $U$ = particle velocity, positive in the direction of gravity, and $V$ = particle volume. The first term on the right-hand side is the net gravitational force on the particle, accounting for buoyancy. The second is the steady-state Stokes drag, Eq. (6-241). The third is the *added mass* or *virtual mass* term, which may be interpreted as the inertial effect of the fluid which is accelerated along with the particle. The volume of the added mass of fluid is one-half the particle volume. The last term, the *Basset force,* depends on the entire history of the transient motion, with past motions weighted inversely with the square root of elapsed time. R. Clift, J. R. Grace, and M. E. Weber [*Bubbles, Drops and Particles,* Academic, New York, 1978] provide integrated solutions. In *turbulent flows,* particle velocity will closely follow fluid eddy velocities when

$$\tau_0 >> \frac{d_p^2[(2\rho_p/\rho)+1]}{36\nu} \tag{6-258}$$

where $\tau_0$ = oscillation period or eddy time scale, the right-hand side expression is the *particle relaxation time,* and $\nu$ = kinematic viscosity.

**Gas Bubbles** Drops and bubbles, unlike rigid solid particles, may undergo deformation and internal circulation. Figure 6-54 shows rise velocity data for air bubbles in stagnant water. In the figure, Eo = Eotvos number, $g(\rho_L - \rho_G)d_e/\sigma$, where $\rho_L$ = liquid density, $\rho_G$ = gas density, $\sigma$ = surface tension, and the equivalent diameter $d_e$ is the diameter of a sphere with volume equal to that of the bubble. Small bubbles (< 1-mm diameter) remain spherical and rise in straight lines. The presence of surface active materials

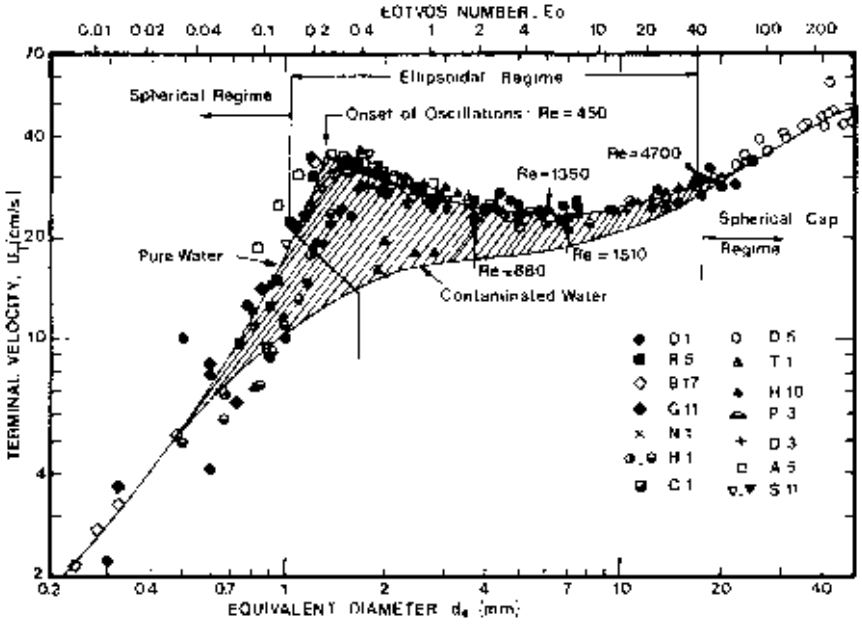

**FIG. 6-54** Terminal velocity of air bubbles in water at 20°C. [From R. Clift, J. R. Grace, and M. E. Weber, *Bubbles, Drops and Particles*, Academic, New York, 1978.]

generally renders small bubbles rigid, and they rise roughly according to the drag coefficient and terminal velocity equations for spherical solid particles. Bubbles roughly in the range 2- to 8-mm diameter assume flattened, ellipsoidal shape, and rise in a zigzag or spiral pattern. This motion increases dissipation and drag, and the rise velocity may actually decrease with increasing bubble diameter in this region, characterized by rise velocities in the range of 20 to 30 cm/s. Large bubbles, > 8-mm diameter, are greatly deformed, assuming a mushroomlike, spherical cap shape. These bubbles are unstable and may break into smaller bubbles. Carefully purified water, free of surface active materials, allows bubbles to freely circulate even when they are quite small. Under creeping flow conditions $\mathrm{Re}_b = d_b u_r \rho_L / \mu_L < 1$, where $u_r$ = bubble rise velocity and $\mu_L$ = liquid viscosity, the bubble rise velocity may be computed analytically from the Hadamard-Rybczynski formula [V. G. Levich, *Physicochemical Hydrodynamics,* Prentice-Hall, Englewood Cliffs, N.J., 1962, p. 402]. When $\mu_G/\mu_L << 1$, which is normally the case, the rise velocity is 1.5 times the rigid sphere Stokes' law velocity. However, in practice, most liquids, including ordinary distilled water, contain sufficient surface active materials to render small bubbles rigid. Larger bubbles undergo deformation in both purified and ordinary liquids; however, the variation in rise velocity for large bubbles with degree of purity is quite evident in Fig. 6-54.

D. G. Karamanev [*Chem. Eng. Comm.* **147:** 75 (1996)] provides equations for bubble rise velocity based on the Archimedes number and on use of the bubble projected diameter $d_h$ in the drag coefficient and the bubble equivalent diameter in Ar. The Archimedes number is as defined in Eq. (6-246) except that the density difference is liquid density minus gas density, and $d_p$ is replaced by $d_e$.

$$u_t = \sqrt{\frac{8g}{6^{2/3}\pi^{1/3}C_D}} V^{1/6} \frac{d_e}{d_h} = \sqrt{\frac{4gd_e}{3C_D}} \frac{d_e}{d_h} \tag{6-259}$$

$$C_D = \frac{432}{\mathrm{Ar}} (1 + 0.0470\,\mathrm{Ar}^{2/3}) + \frac{0.517}{1 + 154\,\mathrm{Ar}^{-1/3}} \qquad \mathrm{Ar} < 13{,}000 \tag{6-260}$$

$$C_D = 0.95 \qquad \mathrm{Ar} > 13{,}000 \tag{6-261}$$

$$\frac{d_e}{d_h} = (1 + 0.163\,Eo^{0.757})^{-1/3} \qquad Eo < 40 \tag{6-262}$$

$$\frac{d_e}{d_h} = 0.62 \qquad Eo > 40 \tag{6-263}$$

Applied to air bubbles in water, these expressions give reasonable agreement with the contaminated water curve in Fig. 6-54.

Figure 6-55 gives the drag coefficient as a function of bubble or drop Reynolds number for air bubbles in water and water drops in air, compared with the standard drag curve for rigid spheres. Information on bubble motion in *nonnewtonian* liquids may be found in G. Astarita and G. Apuzzo [*AIChE J.* **1:** 815–820 (1965)]; P. H. Calderbank et al. [*Chem. Eng. Sci.* **25:** 235–256 (1970)]; and A. Acharya et al. [*Chem. Eng. Sci.* **32:** 863–872 (1977)].

**Liquid Drops in Liquids** Very small liquid drops in immiscible liquids behave as rigid spheres, and the terminal velocity can be approximated by use of the drag coefficient for solid spheres up to a Reynolds number of about 10 [Warshay et al., *Can. J. Chem. Eng.* **37:** 29–36 (1959)]. Between Reynolds numbers of 10 and 500, the terminal velocity exceeds that for rigid spheres owing to internal circulation. J. R. Grace et al. [*Trans. Inst. Chem. Eng.* **54:** 167–173 (1976)]; R. Clift, J. R. Grace, and M. E. Weber [*Bubbles, Drops and Particles,* Academic, New York, 1978, pp. 175–177] present a correlation for terminal velocity valid in the range

$$M < 10^{-3} \qquad Eo < 40 \qquad \mathrm{Re} > 0.1 \tag{6-264}$$

where $M$ = Morton number = $g\mu^4 \Delta\rho / \rho^2 \sigma^3$
$Eo$ = Eotvos number = $g\,\Delta\rho\,d^2/\sigma$
$\mathrm{Re}$ = Reynolds number = $du\rho/\mu$
$\Delta\rho$ = density difference between the phases
$\rho$ = density of continuous liquid phase
$d$ = drop diameter
$\mu$ = continuous liquid viscosity
$\sigma$ = surface tension
$u$ = relative velocity

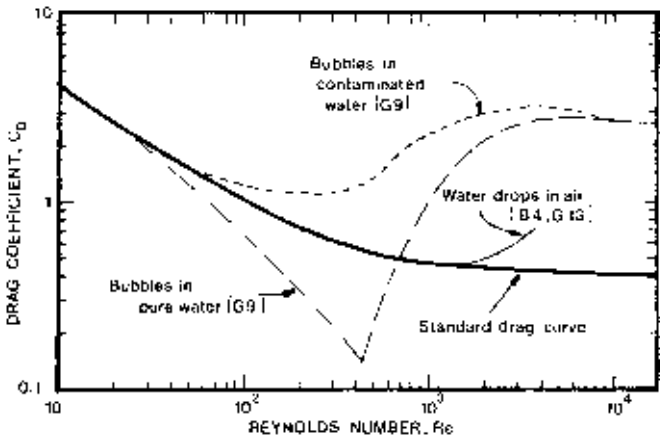

**FIG. 6-55** Drag coefficient for water drops in air and air bubbles in water. Standard drag curve is for rigid spheres. [From R. Clift, J. R. Grace, and M. E. Weber, *Bubbles, Drops and Particles,* Academic, New York, 1978.]

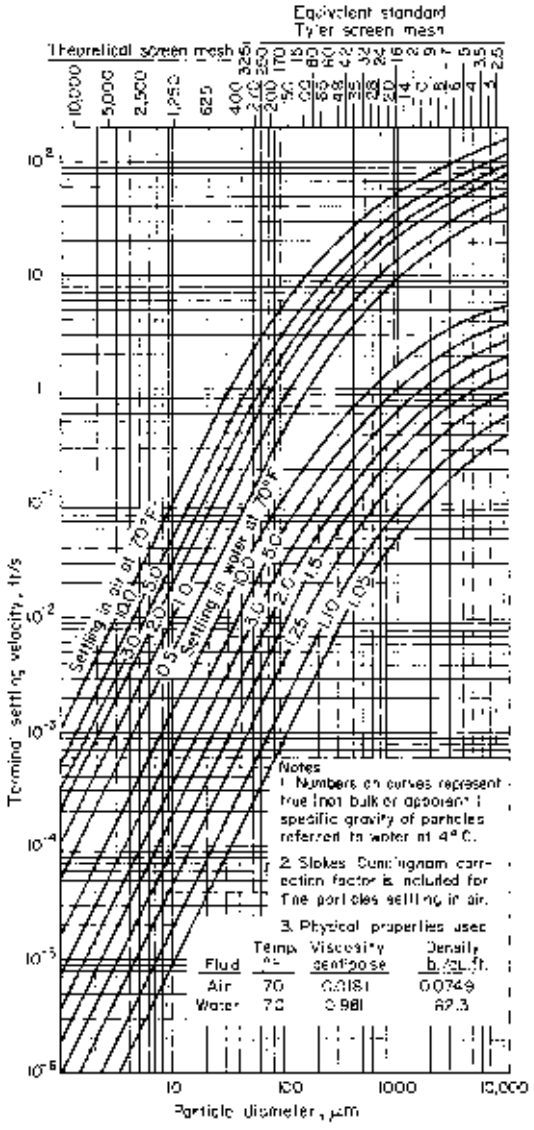

**FIG. 6-56** Terminal velocities of spherical particles of different densities settling in air and water at 70°F under the action of gravity. To convert ft/s to m/s, multiply by 0.3048. [From C. E. Lapple et al., *Fluid and Particle Mechanics*, University of Delaware, Newark, 1951, p. 292.]

The correlation is represented by

$$J = 0.94H^{0.757} \qquad (2 < H \le 59.3) \tag{6-265}$$

$$J = 3.42H^{0.441} \qquad (H > 59.3) \tag{6-266}$$

where $$H = \frac{4}{3}\text{Eo}M^{-0.149}\left(\frac{\mu}{\mu_w}\right)^{-0.14} \tag{6-267}$$

$$J = \text{Re}\,M^{0.149} + 0.857 \tag{6-268}$$

The terminal velocity may be evaluated explicitly from

$$u = \frac{\mu}{\rho d}M^{-0.149}(J - 0.857) \tag{6-269}$$

In Eq. (6-267), $\mu$ = viscosity of continuous liquid and $\mu_w$ = viscosity of water, taken as 0.0009 Pa·s (0.9 cP). This correlation neglects the effect of drop phase viscosity.

For drop velocities in nonnewtonian liquids, see V. Mhatre and R. C. Kinter [*Ind. Eng. Chem.* **51:** 865–867 (1959)]; G. Marrucci et al. [*AIChE J.* **16:** 538–541 (1970)]; and V. Mohan et al. [*Can. J. Chem. Eng.* **50:** 37–40 (1972)].

**Liquid Drops in Gases** Liquid drops falling in stagnant gases appear to remain spherical and follow the rigid sphere drag relationships up to a Reynolds number of about 100. Large drops will deform, with a resulting increase in drag, and in some cases will shatter. The largest water drop that will fall in air at its terminal velocity is about 8 mm (0.32 in) in diameter, with a corresponding velocity of about 9 m/s (30 ft/s). Drops shatter when the Weber number, defined as

$$\text{We} = \frac{\rho_G u^2 d}{\sigma} \tag{6-270}$$

exceeds a critical value. Here, $\rho_G$ = gas density, $u$ = drop velocity, $d$ = drop diameter, and $\sigma$ = surface tension. A value of $\text{We}_c = 13$ is often cited for the critical Weber number.

Terminal velocities for water drops in air have been correlated by E. X. Berry and M. R. Pranger [*J. Appl. Meteorol.* **13:** 108–113 (1974)] as

$$\text{Re} = \exp\left[-3.126 + 1.013\ln N_D - 0.01912(\ln N_D)^2\right] \tag{6-271}$$

**TABLE 6-11 Wall Correction Factor for Rigid Spheres in Stokes' Law Region**

| β* | $k_w$ | β | $k_w$ |
|---|---|---|---|
| 0.0 | 1.000 | 0.4 | 0.279 |
| 0.05 | 0.885 | 0.5 | 0.170 |
| 0.1 | 0.792 | 0.6 | 0.0945 |
| 0.2 | 0.596 | 0.7 | 0.0468 |
| 0.3 | 0.422 | 0.8 | 0.0205 |

*β = particle diameter divided by vessel diameter.
SOURCE: From Haberman and Sayre, *David W. Taylor Model Basin Report* 1143, 1958.

for $2.4 < N_D < 10^7$ and $0.1 < \text{Re} < 3550$. The dimensionless group $N_D$ (often called the *Best* number) [R. Clift, J. R. Grace, and M. E. Weber, *Bubbles, Drops and Particles,* Academic, New York, 1978] is given by

$$N_D = \frac{4\rho\Delta\,\rho g d^3}{3\mu^2} \tag{6-272}$$

and is proportional to the similar Archimedes and Galileo numbers.

Figure 6-56 gives calculated settling velocities for solid spherical particles settling in air or water using the standard drag coefficient curve for spherical particles. For fine particles settling in air, the *Stokes-Cunningham correction* has been applied to account for particle size comparable to the mean free path of the gas. The correction is less than 1 percent for particles larger than 16 μm settling in air. Smaller particles are also subject to *Brownian motion.* Motion of particles smaller than 0.1 μm is dominated by Brownian forces and gravitational effects are small.

**Wall Effects** When the diameter of a settling particle is significant compared to the diameter of the container, the settling velocity is reduced. For rigid spherical particles settling with Re < 1, the correction given in Table 6-11 may be used. The factor $k_w$ is multiplied by the settling velocity obtained from Stokes' law to obtain the corrected settling rate. For values of diameter ratio β = particle diameter/vessel diameter less than 0.05, $k_w = 1/(1 + 2.1\beta)$ [F. A. Zenz and D. F. Othmer, *Fluidization and Fluid-Particle Systems,* Reinhold, New York, 1960, pp. 208–209]. In the range $100 < \text{Re} < 10{,}000$, the computed terminal velocity for rigid spheres may be multiplied by $k'_w$ to account for wall effects, where $k'_w$ is given by [T. Z. Harmathy, *AIChE J.* **6:** 281 (1960)]

$$k'_w = \frac{1-\beta^2}{\sqrt{1+\beta^4}} \tag{6-273}$$

For gas bubbles in liquids, there is little wall effect for $\beta < 0.1$. For $\beta > 0.1$, see S. Uto and R. C. Kintner [*AIChE J.* **2:** 420–424 (1956)], C. C. Maneri and H. D. Mendelson [*Chem. Eng. Prog.* **64,** *Symp. Ser.* **82:** 72–80 (1968)], and R. Collins [*J. Fluid Mech.* **28:** part 1, 97–112 (1967)].

**Nomenclature and Units**

The component $A$ is identified by the subscript $a$. Thus, the number of moles is $n_a$; the fractional conversion is $X_a$; the extent of reaction is $\xi_a$; the partial pressure is $p_a$; the rate of reaction is $r_a$; the molar flow rate is $N_a$; the volumetric flow rate is $q$; the reactor volume is $V$, or simply $V$ for batch reactors; the volumetric concentration is $C_a = n_a/V$ or $C_a = N_a/q$; the total pressure is $P$; and the temperature is $T$. Throughout this section, equations are presented without specification of units. Use of any consistent unit set is appropriate.

Following is a listing of typical nomenclature expressed in SI and U.S. Customary System units.

| Symbol | Definition | SI units | U.S. Customary System units |
|---|---|---|---|
| $A, B, C, \ldots$ | Names of substances | | |
| $a$ | Activity, gas-liquid interfacial area per unit volume of reactor | | |
| BR | Batch reactor | | |
| $b$ | Estimate of kinetic parameters, vector | | |
| $C_a$ | Concentration of substance $A$ | kg·mol/m$^3$ | lb·mol/ft$^3$ |
| CSTR | Continuous stirred tank reactor | | |
| $C_0$ | Initial or inlet concentration | kg·mol/m$^3$ | lb·mol/ft$^3$ |
| $c_p$ | Heat capacity at constant pressure | kJ/(kg·mol·K) | Btu/(lb·mol·°F) |
| $\Delta c_p$ | Heat capacity change in a reaction | kJ/(kg·mol·K) | Btu/(lb·mol·°F) |
| $D$ | Diffusivity, dispersion coefficient | m$^2$/s | ft$^2$/s |
| $D_e$ | Effective diffusivity | m$^2$/s | ft$^2$/s |
| $D_K$ | Knudsen diffusivity | m$^2$/s | ft$^2$/s |
| $E$ | Activation energy, enhancement factor for gas-liquid mass transfer with reaction, electrochemical cell potential | | |
| $F, F_1$ | Faraday constant, $F$ statistic, monomer $A$ mol fraction in polymer | | |
| $f_1, f_2$ | Efficiency of initiation in polymerization, monomer $A$ and $B$ mole fractions | | |
| $\Delta G$ | Free energy change | kJ/kg·mol | Btu/lb·mol |
| Ha | Hatta number | | |
| He | Henry constant for absorption of gas in liquid | | |
| $\Delta H_r$ | Heat of reaction | kJ/kg·mol | Btu/lb·mol |
| $I$ | Initiator species for polymerization, modified Bessel functions, electric current | | |
| $j$ | Electric current density | A/m$^2$ | |
| $K_a$ | Adsorption constant | | |
| $K_e$ | Chemical equilibrium constant | | |
| $k$ | Specific rate constant of reaction, mass transfer coefficient | | |
| $L$ | Length of path in reactor | m | ft |
| LFSS | Lack of fit sum of squares | | |
| $M$ | Average molecular weight in polymers, dead polymer species, monomer species | | |
| MWD | Molecular weight distribution in polymers | | |
| $m$ | Number of moles in electrochemical reaction | kg·mol | lb·mol |
| $N$ | Molar flow rate, molar flux | | |
| NCLD | Number chain length distribution | | |
| NMWD | Number molecular weight distribution | | |
| $n$ | Number of stages in a network of CSTRs, reaction order, number of electrons in electrochemical reaction, number of experiments | | |
| $n_a$ | Number of moles of $A$ | kg·mol | lb·mol |
| $n_t$ | Total number of moles | kg·mol | lb·mol |
| $P$ | Total pressure | Pa | psi |
| $P$ | Live polymer species | | |
| PD | Polydispersity in polymers | | |
| PESS | Pure error sum of squares | | |
| PFR | Plug flow reactor | | |
| $p$ | Number of kinetic parameters | | |
| $p_a$ | Partial pressure of substance $A$ | Pa | psi |
| $q$ | Volumetric flow rate | m$^3$/s | ft$^3$/s |
| $Q$ | Electric charge | C | |
| $Q$ | Live polymer species | | |
| $R$ | Radial position, radius, universal gas constant, initiator radical species | | |
| Re | Reynolds number | | |
| RgSS | Regression sum of squares | | |
| RSS | Residual sum of squares | | |
| $r_a, r_1, r_2$ | Rate of reaction per unit volume, reactivity ratios in polymerization | | |
| $S$ | Selectivity, stoichiometric matrix, objective function for parameter estimation | | |
| SBR | Semibatch reactor | | |
| Sc | Schmidt number | | |
| Sh | Sherwood number | | |
| $\Delta S$ | Entropy change | kJ/(kg·mol·K) | Btu/(lb·mol·°R$_r$) |
| $s$ | Estimate of variance | | |
| $t$ | Time, $t$ statistic | | |
| $u$ | Linear velocity | m/s | ft/s |
| $V$ | Volume of reactor, variance-covariance matrix | | |
| $\upsilon$ | Molar volume | m$^3$/kg·mol | ft$^3$/lb·mol |
| $W$ | Condensation product species in polymerization | | |
| WCLD | Weight chain length distribution | | |
| WMWD | Weight molecular weight distribution | | |
| $w$ | Molecular weight of repeat unit in polymers | | |
| $X$ | Linear model matrix for parameter estimation, fractional conversion | | |
| $X_a$ | $1 - f_a = 1 - C_a/C_{a0}$ or $1 - n_a/n_{a0}$, fractional conversion of component $A$ | | |
| $x$ | Axial position in a reactor, mole fraction in liquid | | |
| $Y$ | Yield, yield coefficient for biochemical reactions | | |
| $y$ | Mole fraction in gas, dependent variable | | |
| $z$ | $x/L$, normalized axial position | | |
| | Greek letters | | |
| $\alpha$ | Fraction of initial catalyst activity, probability of propagation for chain polymerization, conversion for step polymerization, confidence level | | |
| $\beta$ | $r/R$, normalized radial position, fraction of poisoned catalyst, kinetic parameter vector | | |
| $\delta$ | Film thickness or boundary layer thickness, relative change in number of moles by reaction | | |
| $\delta(t)$ | Unit impulse input, Dirac function | | |
| $\varepsilon$ | Relative change in number of moles by reaction, residual error, catalyst particle porosity, current efficiency | | |
| $\Phi$ | Weisz Prater parameter | | |
| $\varphi$ | Thiele modulus | | |
| $\eta$ | Effectiveness factor of porous catalyst, over potential in electrochemical reactions | | |
| $\lambda$ | Parameter for instantaneous gas-liquid reaction, moments in polymer chain length | | |
| $\mu$ | Viscosity, biomass growth rate, average chain length or degree of polymerization in polymers | | |
| $\nu$ | Stoichiometric coefficient, kinematic viscosity, fraction of surface covered by adsorbed species | | |
| $\theta$ | Dimensionless time | | |
| $\rho$ | Density | kg/m$^3$ | lbm/ft$^3$ |
| $\sigma$ | Variance | | |
| $\tau$ | Residence time, tortuosity factor | | |
| $\xi$ | Extent of reaction | | |

**Nomenclature and Units** (*Continued*)

| Symbol | Definition | SI units | U.S. Customary System units |
|---|---|---|---|
| | Subscripts | | |
| act | Activation | | |
| anode | At anode | | |
| B | Bed | | |
| cathode | At cathode | | |
| cell | Electrochemical cell | | |
| $D$ | Diffusion, dispersion | | |
| $d$ | Deactivation | | |
| $e$ | Equilibrium | | |
| $f$ | Forward reaction, final, formation | | |
| $G$ | Gas | | |
| $i$ | Component $i$ | | |
| $j$ | Reaction $j$, chain length in polymers, current | | |
| $L$ | Liquid | | |
| $m$ | Based on mass, mass transfer, chain length in polymers | | |
| max | Maximum biomass growth rate, maximum extent of reaction | | |
| $n$ | Chain length in polymers, number average | | |
| $o$ | Oxidized | | |
| obs | Observed | | |
| $p$ | Particle | | |
| projected | Electrode projected area | | |
| $r$ | Reverse reaction, reduced | | |

# INTRODUCTION

The mechanism and corresponding kinetics provide the rate at which the chemical or biochemical species in the reactor system react at the prevailing conditions of temperature, pressure, composition, mixing, flow, heat, and mass transfer. Observable kinetics represent the true intrinsic chemical kinetics only when competing phenomena such as transport of mass and heat are not limiting the rates. The intrinsic chemical mechanism and kinetics are unique to the reaction system. Knowledge of the intrinsic kinetics therefore facilitates reactor selection, choice of optimal operating conditions, and reactor scale-up and design, when combined with understanding of the associated physical and transport phenomena for different reactor scales and types.

This section covers the following key aspects of reaction kinetics:

- Chemical mechanism of a reaction system and its relation to kinetics
- Intrinsic kinetic rates using equations that can be correlative, lumped, or based on detailed elementary kinetics
- Catalytic kinetics
- Effect of mass and heat transfer on kinetics in heterogeneous systems
- Intrinsic kinetic rates from experimental data and/or from theoretical calculations
- Kinetic parameter estimation

The use of reaction kinetics for analyzing and designing suitable reactors is discussed in Sec. 19.

# BASIC CONCEPTS

## MECHANISM

The mechanism describes the reaction steps and the relationship between the reaction rates of the chemical components. A single chemical reaction includes reactants *A, B,* … and products *R, S,* …

$$\nu_a A + \nu_b B + \cdots \Leftrightarrow \nu_r R + \nu_s S + \cdots \tag{7-1}$$

where $\nu_i$ are the *stoichiometric coefficients* of components *A, B,* …, i.e., the relative number of molecules of *A, B,* … that participate in the reaction. For instance, the HBr synthesis has the global stoichiometry $H_2 + Br_2 \Leftrightarrow 2HBr$.

The *stoichiometry* of the reaction defines the elemental balance (atoms of H and Br, for instance) and therefore relates the number of molecules of reactants and products participating in the reaction. The stoichiometric coefficients are not unique for a given reaction, but their ratios are unique. For instance, for the HBr synthesis above we could have written the stoichiometric equation $\frac{1}{2}H_2 + \frac{1}{2}Br_2 \Leftrightarrow HBr$ as well.

Often several reactions occur simultaneously, resulting in a *network of reactions*. When the network is broken down into *elementary* or *single-event* steps (such as a single electron transfer), the network represents the *true mechanism* of the chemical transformations leading from initial reactants to final products through intermediates. The intermediates can be molecules, ions, free radicals, transition state complexes, and other moieties. A network of *global reactions*, with each reaction representing the combination of a number of elementary steps, does not represent the true mechanism of the chemical transformation but is still useful for global reaction rate calculations, albeit empirically. The stoichiometry can only be written in a unique manner for elementary reactions, since, as shown later, the reaction rate for elementary reactions is determined directly by the stoichiometry through the concept of the law of mass action.

## REACTION RATE

The *specific rate* of consumption or production of any reaction species *i*, denoted $r_i$, is the rate of change of the number of molecules of species *i* with time per unit volume of reaction medium:

$$r_i = \frac{1}{V}\frac{dn_i}{dt} \tag{7-2}$$

The rate is negative when *i* represents a *reactant* ($dn_i/dt$ is negative since $n_i$ is decreasing with time) and positive when *i* represents a *product* ($dn_i/dt$ is positive since $n_i$ is increasing with time). The specific rate of a reaction, e.g., that in Eq. (7-1), is defined as

$$\begin{aligned} r &= -r_i/\nu_i \qquad \text{for reactants} \\ r &= r_i/\nu_i \qquad \text{for products} \end{aligned} \tag{7-3}$$

By this definition, the specific rate of reaction is uniquely defined, and its sign is always positive. Conversely, the rate of reaction of each component or species participating in the reaction is the specific reaction rate multiplied by the species' stoichiometric coefficient with the corrected sign (negative for reactants, positive for products).

## CLASSIFICATION OF REACTIONS

Reactions can be classified in several ways. On the basis of *mechanism* they may be

1. *Irreversible*, i.e., the reverse reaction rate is negligible: $A + B \Rightarrow C + D$, e.g., CO oxidation: $CO + \frac{1}{2}O_2 \Rightarrow CO_2$
2. *Reversible*: $A + B \Rightarrow C + D$, e.g., the water-gas shift $CO + H_2O \Leftrightarrow CO_2 + H_2$
3. *Equilibrium*, a special case with zero net rate, i.e., with the forward and reverse reaction rates of a reversible reaction being equal. All reversible reactions, if left to go to completion, end in equilibrium.
4. *Networks of simultaneous reactions*, i.e., consecutive, parallel, complex (combination of consecutive and parallel reactions):

$$A + B \Rightarrow C + D \qquad C + E \Rightarrow F + G$$

for example two-step hydrogenation of acetylene to ethane

$$CH{\equiv}CH + H_2 \Rightarrow CH_2{=}CH_2 \qquad CH_2{=}CH_2 + H_2 \Rightarrow CH_3CH_3$$

A further classification is from the point of view of the number of reactant molecules participating in the reaction, or the *molecularity*:

1. *Unimolecular*: $A \Rightarrow B$, e.g., isomerization of ortho-xylene to para-xylene, *O*-xylene ⇒ *P*-xylene, or $A \Rightarrow B + C$, e.g., decomposition $CaCO_3 \Rightarrow CaO + CO_2$
2. *Bimolecular*: $A + B \Rightarrow C$ or $2A \Rightarrow B$ or $A + B \Rightarrow C + D$, e.g., $C_2H_4 + H_2 \Rightarrow C_2H_6$
3. *Trimolecular*: $A + B + C \Rightarrow D$ or $3A \Rightarrow B$

This last classification has fundamental meaning only when considering elementary reactions, i.e., reactions that constitute a single chemical transformation or a single event, such as a single electron transfer. For elementary reactions, molecularity is rarely higher than 2. Often elementary reactions are not truly unimolecular, since in order for the reaction to occur, energy is required and it can be obtained through collision with other molecules such as an inert solvent or gas. Thus the unimolecular reaction $A \Rightarrow B$ in reality could be represented as a bimolecular reaction $A + X \Rightarrow B + X$, i.e., *A* collides with *X* to produce *B* and *X,* and thus no net consumption of *X* occurs.

Reactions can be further classified according to the *phases* present. Examples for the more common cases are

1. *Homogeneous gas,* e.g., methane combustion
2. *Homogeneous liquid,* e.g., acid/base reactions to produce soluble salts
3. *Heterogeneous gas-solid*, e.g., HCN synthesis from $NH_3$, $CH_4$, and air on a solid catalyst
4. *Heterogeneous gas-liquid,* e.g., absorption of $CO_2$ in amine solutions
5. *Heterogeneous liquid-liquid,* e.g., reaction in immiscible organic and aqueous phases such as synthesis of adipic acid from cyclohexanone and nitric acid
6. *Heterogeneous liquid-solid,* e.g., reaction of limestone with sulfuric acid to make gypsum
7. *Heterogeneous solid-solid,* e.g., self-propagating high-temperature synthesis (SHS) of inorganic pure oxides
8. *Heterogeneous gas-liquid-solid,* e.g., catalytic Fischer-Tropsch synthesis of hydrocarbons on solid catalyst from CO and $H_2$
9. *Heterogeneous gas-liquid-liquid,* e.g., oxidations or hydrogenations with phase transfer catalysts

Reactions can also be classified with respect to the *mode of operation* in the reaction system (e.g. versus the mode of temperature control) as

1. *Isothermal constant volume* (batch)
2. *Isothermal constant pressure* (continuous)
3. *Adiabatic*
4. *Nonisothermal temperature-controlled* (*by cooling or heating*), *batch or continuous*

## EFFECT OF CONCENTRATION ON RATE

The *concentration* of the reaction components determines the rate of reaction. For instance, for the irreversible reaction

$$pA + qB \Rightarrow rC + sD \tag{7-4}$$

the rate can be represented *empirically* as a power law function of the reactant concentrations such as

$$r = k\, C_a^m C_b^n \qquad C_i = \frac{n_i}{V} \tag{7-5}$$

The exponents *m* and *n* represent the *order of the reaction* with respect to components *A* and *B,* and the *sum m + n* represents the *overall order of the reaction*. The order can be a positive, zero, or negative number indicating that the rate increases, is independent of, or decreases with an increase in a species concentration, respectively. The exponents can be whole (integral order) or fraction ( fractional order). In Eq. (7-5) *k* is the *specific rate constant* of the reaction, and it is independent of concentrations for elementary reactions only. For global reactions consisting of several elementary steps, *k* may still be constant over a narrow range of compositions and operating conditions and therefore can be considered independent of concentration for limited practical purposes. A further complexity arises for nonideal chemical solutions where activities have to be used instead of concentrations. In this case the rate constant can be a function of composition even for elementary steps (see, for instance, Froment and Bischoff, *Chemical Reactor Analysis and Design,* 2d ed., Wiley, 1990).

When Eq. (7-4) represents a global reaction combining a number of elementary steps, then rate equation (7-5) represents an empirical correlation of the global or overall reaction rate. In this case, exponents *m* and *n* have no clear physical meaning other than indicating the overall effect of the various concentrations on rate, and they do not have any obvious relationship to the stoichiometric coefficients *p* and *q*. This is not so for elementary reactions,

as shown in the next subsection. Also, as shown later, power law and rate expressions other than power law (e.g., hyperbolic) can be developed for specific reactions by starting with the mechanism of the elementary steps and making simplifying assumptions that are valid under certain conditions.

## LAW OF MASS ACTION

As indicated above, the dependence of rate on concentration can be shown to be of the general form

$$r = kf(C_a, C_b, \ldots) \tag{7-6}$$

For elementary reactions, the *law of mass action* states that the rate is proportional to the concentrations of the reactants raised to the power of their respective molecularity. Thus for an elementary irreversible reaction such as Eq. (7-4) the rate equation is

$$r = k\, C_a^p\, C_b^q \tag{7-7}$$

Hence, the exponents $p$ and $q$ of Eq. (7-7) are the stoichiometric coefficients when the stoichiometric equation truly represents the mechanism of reaction, i.e., when the reactions are elementary. As discussed above, the exponents $m$ and $n$ in Eq. (7-5) identify the order of the reaction, while the stoichiometric coefficients $p$ and $q$ in Eq. (7-7) identify the molecularity—for elementary reactions these are the same.

## EFFECT OF TEMPERATURE

The *Arrhenius equation* relates the specific rate constant to the absolute temperature

$$k = k_0 \exp\left(-\frac{E}{RT}\right) \tag{7-8}$$

where $E$ is called the *activation energy* and $k_0$ is the *preexponential* factor. As seen from Eq. (7-8), the rate can be a very strongly increasing (exponential) function of temperature, depending on the magnitude of the activation energy $E$. This equation works well for elementary reactions, and it also works reasonably well for global reactions over a relatively narrow range of temperature in the absence of mass transfer limitations. The Arrhenius form represents an energy barrier on the reaction pathway between reactants and products that has to be overcome by the reactant molecules.

The Arrhenius equation can be derived from theoretical considerations using either of two competing theories: *collision theory* and *transition state theory*. A more accurate form of Eq. (7-8) includes an additional temperature factor

$$k = k_0 T^m \exp\left(-\frac{E}{RT}\right) \qquad 0 < m < 1 \tag{7-9}$$

but the $T^m$ factor is often neglected because of the usually much stronger dependence on temperature of the exponential factor in Eq. (7-9), as $m$ is usually small. When $m$ is larger, as it can be for complex molecules, then the $T^m$ term has to be taken into consideration. For more details, see Masel, *Chemical Kinetics and Catalysis,* Wiley, 2001; and Levenspiel, *Chemical Reaction Engineering,* 3d ed., Wiley, 1999.

## HEAT OF REACTION

Chemical reactions are accompanied by evolution or absorption of energy. The enthalpy change (difference between the total enthalpy of formation of the products and that of the reactants) is called the *heat of reaction* $\Delta H_r$:

$$\Delta H_r = (\nu_r H_{fr} + \nu_s H_{fs} + \cdots) - (\nu_a H_{fa} + \nu_b H_{fb} + \cdots) \tag{7-10}$$

where $H_{fi}$ are the *enthalpies of formation* of components $i$. The reaction is *exothermic* if heat is produced by the reaction (negative heat of reaction) and *endothermic* if heat is consumed (positive heat of reaction). The heat of reaction depends upon the temperature range and the phases of the reactants and product. To estimate the dependence of the heat of reaction on temperature relative to a reference temperature $T_0$, the following expression can be used, provided there is no phase change:

$$\begin{aligned} \Delta H_r(T) &= \Delta H_r(T_0) + \int_{T_0}^{T} \Delta c_p\, dT \\ \Delta c_p &= (\nu_r c_{pr} + \nu_s c_{ps} + \cdots) - (\nu_a c_{pa} + \nu_b c_{pb} + \cdots) \end{aligned} \tag{7-11}$$

where the $c_{pi}$ are the constant-pressure *heat capacities* of component $i$. The heat of reaction can be measured by using calorimetry, or it can be calculated by using a variety of thermodynamic methods out of the scope of this chapter (see Sec. 4 of this handbook, thermodynamic text books, and Bird, Stewart, and Lightfoot, *Transport Phenomena,* 2d ed., Wiley, New York, 2002). It is important to accurately capture the energy balance and its relation to the heat of reaction and heat capacities (see also Denn, *Process Modeling,* Longman, New York, 1986, for correct formulations). The coupling of the heat of reaction with the reaction rate often has a dominating effect on reactor selection and control, and on the laboratory reactor setup required to obtain accurate intrinsic kinetics and mechanisms. A more detailed discussion of this topic can be found in Sec. 19.

## CHEMICAL EQUILIBRIUM

Often reactions or reaction steps in a network of reactions are at chemical equilibrium; i.e., the rate of the forward reaction equals the rate of the reverse reaction. For instance, for the reversible reaction

$$\nu_a \mathrm{A} + \nu_b B \underset{k_r}{\overset{k_f}{\Leftrightarrow}} \nu_r R + \nu_s S \tag{7-12}$$

with mass action kinetics, the rate may be written as

$$r = r_f - r_r = k_f C_a^{\nu_a} C_b^{\nu_b} - k_r C_r^{\nu_r} C_s^{\nu_s} \tag{7-13}$$

At chemical equilibrium the forward and reverse reaction rates are equal:

$$r = r_f - r_r = 0 \tag{7-14}$$

The equilibrium constant $K_e$ (based on volumetric concentrations) is defined as the ratio of the forward and reverse rate constants and is related to the composition at equilibrium as follows:

$$K_e = \frac{k_f}{k_r} = \frac{C_{r,e}^{\nu_r} C_{s,e}^{\nu_s}}{C_{a,e}^{\nu_a} C_{b,e}^{\nu_b}} \tag{7-15}$$

The equilibrium constant $K_e$ can be calculated from the free energy change of the reaction. Using the van't Hoff relation, we obtain the dependence of $K_e$ on temperature:

$$\frac{d(\ln K_e)}{dT} = \frac{\Delta H_r}{RT^2} \tag{7-16}$$

Integrating with respect to temperature, we obtain a form similar to the Arrhenius expression of the rate constant for a narrow range of temperature with $\Delta H_r$ assumed constant:

$$K_e = K_{e0} \exp\left(-\frac{\Delta H_r}{RT}\right) \tag{7-17}$$

A more general integral form of Eq. (7-16) is

$$\ln K_e(T) = \ln K_e(T_0) + \frac{1}{R}\int_{T_0}^{T} \frac{\Delta H_r(T_0) + \int_{T_0}^{T} \Delta c_p\, dT}{T^2}\, dT \tag{7-18}$$

When a reversible reaction is not at equilibrium, knowledge of $K_e$ can be used to eliminate the rate constant of the reverse reaction by using Eq. (7-15) as follows:

$$r = k_f (C_a^{\nu_a} C_b^{\nu_b} - C_r^{\nu_r} C_s^{\nu_s} / K_e) \tag{7-19}$$

When several reversible reactions occur simultaneously, each reaction $r_j$ is characterized by its equilibrium constant $K_{ej}$. When the $K_{ej}$ are known, the composition at equilibrium can be calculated from a set of equations such as Eq. (7-15) for each reaction. At equilibrium, according to the principle of *microscopic reversibility* or *detailed balancing*, each reaction in the network is at equilibrium.

## CONVERSION, EXTENT OF REACTION, SELECTIVITY, AND YIELD

*Conversion* of a reactant is the number of moles converted per initial or feed moles of a reactant. Thus for component $A$

$$X_a = 1 - \frac{n_a}{n_{a0}} \tag{7-20}$$

A *limiting reactant* is a reactant whose concentration at the start of the reaction is the least of all reactants relative to the required stoichiometric amount needed for complete conversion. For instance, for the single

reaction in Eq. (7-12), $A$ is the limiting reactant if the initial molar ratio of concentrations of $A$ and $B$ is less than the ratio of their stoichiometric coefficients:

$$\frac{n_{a0}}{n_{b0}} < \frac{\nu_a}{\nu_b} \tag{7-21}$$

Once the limiting reactant is depleted, the respective reaction stops even though other (nonlimiting) reactants may still be abundant.

For each reaction or each step in a network of reactions, a unique *extent of reaction* $\xi$ that relates the composition of components that participate in the reaction to one another can be defined. For instance, for the single reaction in Eq. (7-1):

$$\xi = \frac{n_{a0} - n_a}{\nu_a} = \frac{n_{b0} - n_b}{\nu_b} = \cdots = -\frac{n_{r0} - n_r}{\nu_r} = -\frac{n_{s0} - n_s}{\nu_s} = \cdots \tag{7-22}$$

The extent of reaction is related to conversion as follows:

$$\xi = \frac{X_a n_{a0}}{\nu_a} = \frac{X_b n_{b0}}{\nu_b} = \cdots \tag{7-23}$$

When $A$ is the limiting reactant as in Eq. (7-21), the maximum extent of reaction (with $A$ fully converted) is

$$\xi_{\max} = \frac{n_{a0}}{\nu_a} \tag{7-24}$$

For multiple reactions with reactants participating in more than one reaction, it is more difficult to determine the limiting reactant, and often it is necessary to calculate the concentration as the reactions proceed to determine which reactant is consumed first. When the limiting reactant is depleted, all reactions that use this component as reactant stop, and the corresponding rates become zero.

*Selectivity* $S$ of a product is the ratio of the rate of production of that product to the rate of production of all products combined. For a single reaction selectivity is trivial—if more than one product occurs, then the selectivity of each product is the ratio of the stoichiometric coefficient of that product to the sum of stoichiometric coefficients of all the products. Thus for the reaction in Eq. (7-1)

$$S_r = \frac{\nu_r}{\nu_r + \nu_s + \cdots} \tag{7-25}$$

The selectivity of product $R$ for a network of reactions, with all the reactions making the various products included, is

$$S_r = \frac{r_r}{\sum_{\text{all products } i} r_i} \tag{7-26}$$

For instance, for the network of reactions $A + B \overset{1}{\Rightarrow} C + D$ and $C + E \overset{2}{\Rightarrow} F + G$, the selectivity to product $C$ is

$$S_C = \frac{r_c}{r_c + r_d + r_f + r_g} = \frac{r_1 - r_2}{(r_1 - r_2) + r_1 + r_2 + r_2} = \frac{r_1 - r_2}{2r_1 + r_2}$$

The *yield* $Y$ of a product $R$ with respect to a reactant $A$ is the ratio of the rate of production of $R$ to that of consumption of $A$:

$$Y_r = \frac{r_r}{-r_a} \tag{7-27}$$

For a single reaction the yield is trivial, and Eq. (7-27) simplifies to the ratio of the respective stoichiometric coefficients:

$$Y_r = \frac{\nu_r}{-\nu_a} \tag{7-28}$$

The yield quantifies the efficiency of the respective reactant utilization to make the desired products.

## CONCENTRATION TYPES

Different concentration types are used for different reaction systems. For gas-phase reactions, *volumetric concentration* or *partial pressures* are equally useful, and these can be related by the thermodynamic equation of state. For instance, for ideal gases (approximation valid for gases at very low pressure)

$$PV = nRT \tag{7-29}$$

When it is applied to individual components in a constant-volume system,

$$p_i V = n_i RT \tag{7-30}$$

Using Eq. (7-5), we obtain the relationship between the volumetric concentrations and partial pressures:

$$C_i = \frac{p_i}{RT} \tag{7-31}$$

For an ideal gas, the total concentration is

$$C = \frac{P}{RT} \tag{7-32}$$

For higher pressure and nonideal gases, a *compressibility factor* $z_i$ can be used:

$$p_i V = z_i n_i RT \quad \text{and} \quad C_i = \frac{p_i}{z_i RT} \tag{7-33}$$

Other relevant equations of state can also be used for both gases and liquids. This aspect is not in the scope of this section, and the reader is referred to Sec. 4 of this handbook.

Other concentration units include *mole fractions* for liquid $x_i$:

$$x_i = \frac{n_i}{\sum n_i} = \frac{C_i}{\sum C_i} = \frac{C_i}{C} \tag{7-34}$$

and for gas $y_i$

$$y_i = \frac{n_i}{\sum n_i} = \frac{C_i}{\sum C_i} = \frac{C_i}{C} = \frac{p_i}{\sum p_i} = \frac{p_i}{P} \tag{7-35}$$

The last two terms are only valid for an ideal gas.

## STOICHIOMETRIC BALANCES

**Single Reactions** Equation (7-22) shows that for a single reaction, the number of moles and concentration of all other components can be calculated from the extent of reaction $\xi$ or the conversion based on the limiting reactant, say $A$, $X_a$. In terms of number of moles $n_i$,

$$\begin{aligned}
n_a &= n_{a0} - \nu_a \xi = n_{a0}(1 - X_a) \\
n_b &= n_{b0} - \nu_b \xi = n_{b0}(1 - X_b) = n_{b0} - \frac{\nu_b}{\nu_a} n_{a0} X_a \\
&\cdots \\
n_r &= n_{r0} + \nu_r \xi = n_{r0} + \frac{\nu_r}{\nu_a} n_{a0} X_a \\
n_s &= n_{s0} + \nu_s \xi = n_{s0} + \frac{\nu_s}{\nu_a} n_{a0} X_a \\
&\cdots
\end{aligned} \tag{7-36}$$

Similarly, the number of moles of each component in terms of moles of $A$, $n_a$, is

$$\begin{aligned}
n_b &= n_{b0} - \frac{\nu_b}{\nu_a}(n_{a0} - n_a) \\
&\cdots \\
n_r &= n_{r0} + \frac{\nu_r}{\nu_a}(n_{a0} - n_a) \\
n_s &= n_{s0} + \frac{\nu_s}{\nu_a}(n_{a0} - n_a) \\
&\cdots
\end{aligned} \tag{7-37}$$

Change in number of moles by the reaction and change in temperature, pressure, and density affect the translation of stoichiometric balances from number of moles to volumetric concentrations. These relationships are different for gases and liquids. For instance, for *constant-density* systems (such as many liquid-phase isothermal reactions) or for *constant-temperature, constant-pressure* gas reaction with no change in number of moles, Eqs. (7-36) and (7-37) can be changed to volumetric concentration $C_i$ by dividing each

equation by the constant reaction volume $V$ (e.g., in a batch reactor) and using Eq. (7-5). For example, for the single reaction in Eq. (7-4) with the rate in Eq. (7-5):

$$C_b = C_{b0} - \frac{q}{p}(C_{a0} - C_a)$$

$$C_r = C_{r0} + \frac{r}{p}(C_{a0} - C_a) \tag{7-38}$$

$$C_s = C_{s0} + \frac{s}{p}(C_{a0} - C_a)$$

$$r = kC_a^m \left[ C_{b0} - \frac{q}{p}(C_{a0} - C_a) \right]^n = k\left[C_{a0}(1 - X_a)\right]^m \left( C_{b0} - \frac{q}{p} C_{a0} X_a \right)^n \tag{7-39}$$

It is best to represent all concentrations in terms of that of the limiting reactant.

Often there is a change in total number of moles due to reaction. Taking the general reaction in Eq. (7-1), in the gas phase the change in number of moles relative to moles of component $A$ converted, $\delta_a$, and the total number of moles can be calculated as follows:

$$\begin{aligned} \delta_a &= \frac{\nu_q + \nu_s + \cdots - \nu_a - \nu_b - \cdots}{\nu_a} \\ n_0 &= \sum n_{i0} \qquad n = \sum n_i \\ \frac{n}{n_0} &= 1 + y_{a0}\,\delta_a X_a = 1 + \varepsilon_a X_a \\ \varepsilon_a &= y_{a0}\delta_a \end{aligned} \tag{7-40}$$

Here $y_{a0}$ is the initial mol fraction of $A$. Using the ideal gas law, Eq. (7-29), the volume change depends on conversion as follows:

$$\frac{V}{V_0} = \frac{T}{T_0}\frac{P_0}{P}\frac{n}{n_0} = \frac{T}{T_0}\frac{P_0}{P}(1 + \varepsilon_a X_a) \tag{7-41}$$

Hence, for an isothermal constant-pressure ideal gas reaction system,

$$\begin{aligned} C_a &= \frac{n_a}{V} = \frac{C_{a0}(1 - X_a)}{1 + \varepsilon_a X_a} \\ C_b &= \frac{n_b}{V} = \frac{C_{b0} - \frac{\nu_b}{\nu_a} C_{a0} X_a}{1 + \varepsilon_a X_a} \\ &\cdots \\ C_r &= \frac{n_r}{V} = \frac{C_{r0} + \frac{\nu_r}{\nu_a} C_{a0} X_a}{1 + \varepsilon_a X_a} \\ C_s &= \frac{n_s}{V} = \frac{C_{s0} + \frac{\nu_s}{\nu_a} C_{a0} X_a}{1 + \varepsilon_a X_a} \\ &\cdots \end{aligned} \tag{7-42}$$

Applying this to the reaction in Eq. (7-4) and rate in Eq. (7-5) gives

$$r = k\left[ \frac{C_{a0}(1 - X_a)}{1 + \varepsilon_a X_a} \right]^m \left[ \frac{C_{b0} - (q/p) C_{a0} X_a}{1 + \varepsilon_a X_a} \right]^n \tag{7-43}$$

Compare Eq. (7-43) to Eq. (7-39) where there is no change in number of moles.

**Reaction Networks** The analysis for single reactions can be extended to a network of reactions by defining an extent of reaction for each reaction, or by choosing a representative reactant concentration for each reaction step. For a complex network, the number of independent extents of reaction required to calculate the concentration of all components is equal to the number *of independent reactions*, which is less than or equal to the total number of reactions in the network. To calculate the number of independent reactions, and to form a set of independent reactions and corresponding independent set of concentrations or extents of reaction, we need to construct the *stoichiometric matrix* and determine its *rank*. The stoichiometric matrix is used to derive a relationship between the concentrations and the independent extents of reaction similar to that of a single reaction.

The stoichiometric matrix is the matrix of the stoichiometric coefficients of the reaction network with negative signs for reactants and positive signs for products. For instance, the hydrodechlorination of Freon 12 ($CF_2Cl_2$) can proceed with the following consecutive mechanism [Bonarowska et al., "Hydrodechlorination of $CCl_2F_2$ (CFC-12) over Silica-Supported Palladium-Gold Catalysts," *Appl. Catal. B: Environmental* **30:** 187–193 (2001)]:

$$CF_2Cl_2 + H_2 \Rightarrow CF_2ClH + HCl \qquad CF_2ClH + H_2 \Rightarrow CF_2H_2 + HCl$$

The stoichiometric matrix $S$ for this network is

$$S = \begin{pmatrix} -1 & 1 & 0 & -1 & 1 \\ 0 & -1 & 1 & -1 & 1 \end{pmatrix}$$

The first row refers to the first reaction and the second row to the second reaction. The columns (species) are in the following order: 1-$CF_2Cl_2$, 2-$CF_2ClH$, 3-$CF_2H_2$, 4-$H_2$, and 5-HCl. The rank of a matrix is the largest square submatrix obtained by deleting rows and columns, whose determinant is not zero. The rank equals the number of independent reactions. This is also equivalent to stating that there are reactions in the network that are linear combinations of the independent reactions. The rank of $S$ above is 2, since the *determinant* of the first $2 \times 2$ *submatrix* is not zero (there are other $2 \times 2$ submatrices that are not zero as well but it is sufficient to have at least one that is not zero):

$$S_1 = \begin{pmatrix} -1 & 1 \\ 0 & -1 \end{pmatrix} \quad \det(S_1) = 1 \neq 0$$

Hence the two reactions are independent. Now if we add another step, which converts Freon 12 directly into the final hydrofluorocarbon $CF_2H_2$; $CF_2Cl_2 + 2H_2 \Rightarrow CF_2H_2 + 2HCl$, then the stoichiometric matrix becomes

$$S = \begin{pmatrix} -1 & 1 & 0 & -1 & 1 \\ 0 & -1 & 1 & -1 & 1 \\ -1 & 0 & 1 & -2 & 2 \end{pmatrix}$$

Since the last reaction is a linear combination of the first two (sum), it can be easily proved that the rank remains unchanged at 2. So to conclude, the concentrations of all components in this network can be expressed in terms of two, say $H_2$ and Freon 12, and the first two reactions form an independent reaction set. In case of more complicated networks, it may be difficult to determine the independent reactions by observation alone. In this case the *Gauss-Jordan decomposition* leads to a set of independent reactions (see, e.g., Amundson, *Mathematical Methods in Chemical Engineering—Matrices and Their Application,* Prentice-Hall International, New York, 1966).

For a network of reactions the general procedure is as follows:

1. Generate the reaction network by including all known reaction steps.
2. Generate the corresponding stoichiometric matrix.
3. Calculate the rank of the stoichiometric matrix which equals the number of independent reactions and independent component concentrations required to calculate all the remaining component concentrations.
4. For relatively simple networks, observation allows selection of reactions that are independent—for more complex systems use the Gauss-Jordan elimination to reduce the network to a set of independent (nonzero rows) reactions.
5. Select the independent concentration variables and independent reactions, and use these to calculate all other concentrations and reaction rates.

## CATALYSIS

A *catalyst* is a material that increases the rate of both the forward and reverse reactions of a reaction step, with no net consumption or generation of catalyst by the reaction. A catalyst does not affect the reaction thermodynamics, i.e., the equilibrium composition or the heat of reaction. It does, however, affect the temperature sensitivity of the reaction rate by lowering the activation energy or the energy barrier on the reaction pathway from reactants to products. This allows the reaction to occur faster than the corresponding uncatalyzed reaction at a given temperature. Alternatively, catalytic reactions can proceed at lower temperatures than the corresponding noncatalytic reactions. For a network of reactions, the catalyst is often used to speed up desired reactions and/or to slow down undesired reactions for improved selectivity. On the basis of catalysis, reactions can be further classified into

1. Noncatalytic reactions, e.g., free-radical gas-phase reactions such as combustion of hydrocarbons.

2. Homogeneous catalytic reactions with the catalyst being dissolved in the same phase as the reactants and products in a homogeneous reaction medium. Here the catalyst is uniformly distributed throughout the system, e.g., the hydroformylation of olefins in the presence of dissolved Co or Rh carbonyls.

3. Heterogeneous catalytic reactions, with the catalyst, for instance, being a solid in contact with reactants and products in a gas-solid, gas-liquid-solid, or liquid-solid reaction system. Here the catalyst is not uniformly distributed, and the reaction occurring on the catalyst surface requires, for instance, adsorption of reactants and desorption of products from the solid surface, e.g., the catalytic cracking of gas oil to gasoline and lighter hydrocarbons.

Table 7-1 illustrates the enhancement of the reaction rates by the catalyst—this enhancement can be of many orders of magnitude.

**TABLE 7-1 The Rate of Enhancement of Some Reactions in the Presence of a Catalyst**

| Reaction | Catalyst | Rate enhancement | Temperature, K |
|---|---|---|---|
| Ortho $H_2 \Rightarrow$ para $H_2$ | Pt (solid) | $10^{40}$ | 300 |
| $2NH_3 \Rightarrow N_2 + 3H_2$ | Mo (solid) | $10^{20}$ | 600 |
| $C_2H_4 + H_2 \Rightarrow C_2H_6$ | Pt (solid) | $10^{42}$ | 300 |
| $H_2 + Br_2 \Rightarrow 2HBr$ | Pt (solid) | $1 \times 10^8$ | 300 |
| $2NO + 2H_2 \Rightarrow N_2 + 2H_2O$ | Ru (solid) | $3 \times 10^{16}$ | 500 |
| $CH_3COH \Rightarrow CH_4 + CO$ | $I_2$ (gas) | $4 \times 10^6$ | 500 |
| $CH_3CH_3 \Rightarrow C_2H_4 + H_2$ | $NO_2$ (gas) | $1 \times 10^9$ | 750 |
| $(CH_3)_3COH \Rightarrow$ $(CH_3)_2\,CH_2CH_2 + H_2O$ | HBr (gas) | $3 \times 10^8$ | 750 |

# IDEAL REACTORS

Reactions occur in reactors, and in addition to the intrinsic kinetics, observed reaction rates depend on the reactor type, scale, geometry, mode of operation, and operating conditions. Similarly, understanding of the reactor system used in the kinetic experiments is required to determine the reaction mechanism and intrinsic kinetics. In this section we address the effect of reactor type on observed rates. In Sec. 19 the effect of reactor type on performance (rates, selectivity, yield) is discussed in greater detail.

Material, energy, and momentum balances are essential to fully describe the performance of reactors, and often simplifying assumptions and phenomenological assumptions are needed especially for energy and momentum terms, as indicated in greater detail in Sec. 19 (see also Bird, Stewart, and Lightfoot, *Transport Phenomena,* 2d ed., Wiley, New York, 2002). Ideal reactors allow us to simplify the energy, momentum, and material balances, thus focusing the analysis on intrinsic kinetics. A useful classification of ideal reactor types is in terms of their concentration distributions versus reaction time and space. Three types of ideal reactors are considered in this section:

1. Ideal *batch reactors* (*BRs*) including *semibatch reactors* (*SBRs*)
2. Ideal *continuously stirred tank reactor* (*CSTR*), including single and multiple stages
3. *Plug flow reactor* (*PFR*) with and without *recycle*

The general form of a balance equation is

$$\text{input} + \text{sources} - \text{outputs} = \text{accumulation} \tag{7-44}$$

## IDEAL BATCH REACTOR

**Batch Reactor (BR)** Ideal batch reactors (Fig. 7-1*a*) are tanks provided with agitation for uniform composition and temperature at all times. An ideal batch reactor can be operated under isothermal conditions (constant temperature), temperature-programmed mode (by controlling cooling rate according to a protocol), or adiabatic mode (with no heat crossing the reactor boundaries). In adiabatic mode the temperature is increasing, decreasing, or constant as the reaction proceeds for exothermic, endothermic, and thermally neutral reactions, respectively. In the ideal batch reactor, all the reactants are loaded into the reactor and well mixed by agitation before the conditions for reaction initiation (temperature and pressure) are reached; as the reaction proceeds, the concentration varies with time, but at any one time it is uniform throughout due to agitation.

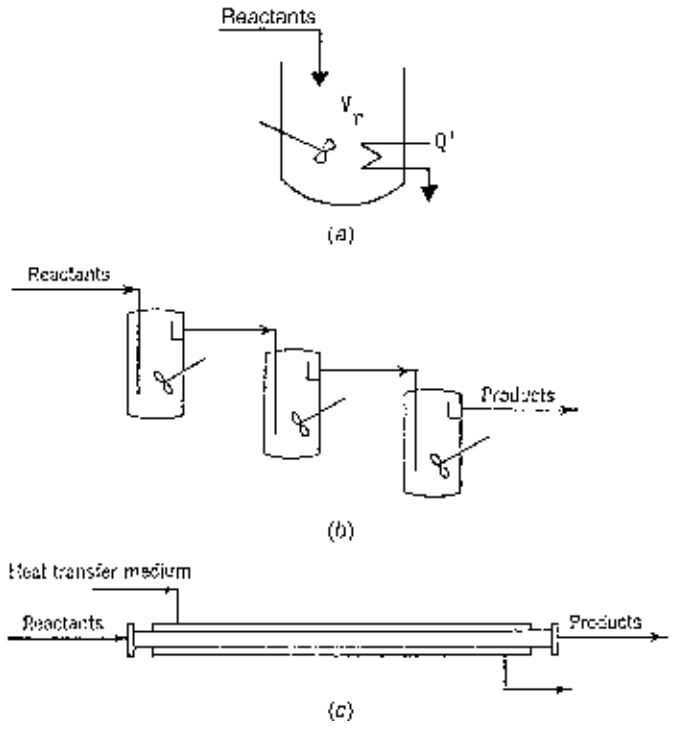

**FIG. 7-1** Types of ideal reactors: (*a*) Batch or semibatch. (*b*) CSTR or series of CSTRs. (*c*) Plug flow.

Laboratory batch reactors can be single-phase (e.g., gas, liquid, etc.), multiphase (e.g., gas-liquid, gas-liquid-solid, etc.), and catalytic or noncatalytic. In this section we limit the discussion to operation at isothermal conditions. This eliminates the need to consider energy, and due to the uniform composition the component material balances are simple ordinary differential equations with time as the independent variable.

An ideal isothermal single-phase batch reactor in which a general reaction network takes place has the following general material balance equation:

$$\frac{dn_i}{dt} = V\sum_j \nu_{ij} r_j \qquad n_i = n_{i0} \qquad \text{at } t = 0 \tag{7-45}$$

The left-hand side is the accumulation term in moles per second of component *i*, and the right-hand side is the source term due to chemical reaction, also in moles per second, which includes all reactions *j* that consume or produce component *i*. The corresponding stoichiometric coefficients are represented in matrix form as $\nu_{ij}$ with a positive sign for products and a negative sign for reactants. This molar balance is valid for each component since we can multiply each side of the equation by the component molecular weight to obtain the true mass balance equation. In terms of conversion, Eq. (7-45) can be rewritten as

$$\frac{n_{i0}dX_i}{dt} = -V\sum \nu_{ij} r_j \qquad n_i = n_{i0} \qquad \text{at } t = 0 \tag{7-46}$$

and we can integrate this equation to get the *batch reaction time* or *batch residence time* $\tau_{BR}$ required to obtain a conversion $X_i$, starting with initial conversion $X_{i0}$ and ending with final conversion $X_{if}$:

$$\tau_{BR} = -n_{i0}\int_{X_{i0}}^{X_{if}} \frac{dX_i}{V\sum \nu_{ij} r_j} \tag{7-47}$$

To integrate we need to represent all reaction rates $r_j$ in terms of the conversion $X_i$. For a single reaction this is straightforward [see, e.g., Eq. (7-43)]. However, for a network of reactions, integration of a system of often nonlinear differential equations is required using implicit or semi-implicit methods. For references please see Sec. 3 of this handbook or any text on ordinary differential equations.

A special case of batch reactors is constant-volume or constant-density operation typical of liquid-phase reactions, with volume invariant with time:

$$\frac{dC_i}{dt} = \sum \nu_{ij} r_j \qquad C_i = C_{i0} \qquad \text{at } t = 0 \tag{7-48}$$

A typical concentration profile versus time for a reactant is shown in Fig. 7-2*a*. Integration of Eq. (7-48) gives the batch residence time

$$\tau_{BR} = \int_{C_{i0}}^{C_{if}} \frac{dC_i}{\sum \nu_{ij} r_j} \tag{7-49}$$

For instance, for a single reaction, Eq. (7-39) can be used to describe the reaction rate $r_i$ in terms of one reactant concentration. For reaction networks, integration of a system of ordinary differential equations is required.

**Semibatch Reactor (SBR)** In semibatch operation, a gas of limited solubility or a liquid reactant may be fed in gradually as it is used up. An ideal isothermal single-phase semibatch reactor in which a general reaction network takes place has the following general material balance equation:

$$\frac{dn_i}{dt} = N_i + V\Sigma \nu_{ij} r_j \qquad n_i = n_{i0} \qquad \text{at } t = 0$$
$$N_i = N_i(t) \qquad \text{for} \qquad t_{s0i} \le t \le t_{sli} \tag{7-50}$$

The first term on the right-hand side of Eq. (7-50) is the molar feed rate of the components, which can be different for each component, hence the subscript *i*, and can vary with time. A typical concentration profile versus time for a reactant whose concentration is kept constant initially by controlling the feed rate is shown in Fig. 7-2*b*. Knowledge of the reaction kinetics allows these ordinary differential equations to be integrated to obtain the reactor composition versus time.

## IDEAL CONTINUOUS STIRRED TANK REACTOR (CSTR)

In an ideal continuous stirred tank reactor, composition and temperature are uniform throughout just as in the ideal batch reactor. But this reactor also has a continuous feed of reactants and a continuous withdrawal of products and unconverted reactants, and the effluent composition and temperature are the same as those in the tank (Fig. 7-1*b*). A CSTR can be operated under transient conditions (due to variation in feed composition, temperature, cooling rate, etc., with time), or it can be operated under steady-state conditions. In this section we limit the discussion to isothermal conditions. This eliminates the need to consider energy balance equations, and due to the uniform composition, the component material balances are simple ordinary differential equations with time as the independent variable:

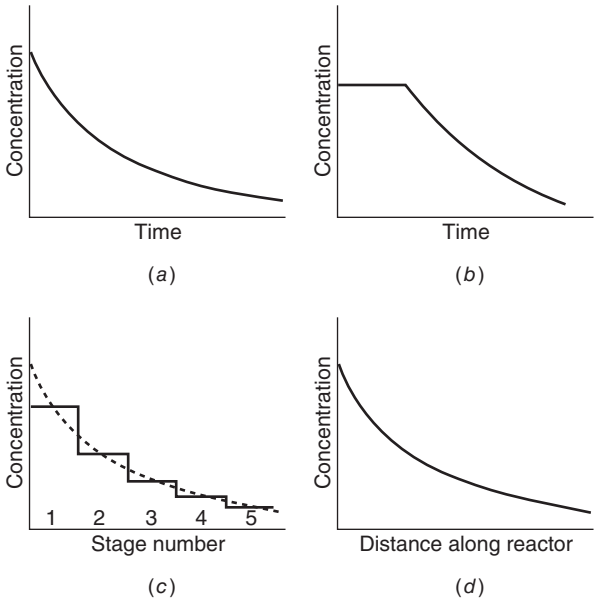

**FIG. 7-2** Concentration profiles in ideal batch and continuous flow: (*a*) Batch time profile. (*b*) Semibatch time profile. (*c*) Five-stage CSTRs profile. (*d*) Plug flow distance profile.

$$\frac{dn_i}{dt} = N_{i0} - N_i + V\sum \nu_{ij} r_j \qquad n_i = n_{i0} \qquad \text{at } t = 0 \tag{7-51}$$

At steady state the differential equations simplify to algebraic equations, and the reactor volume is

$$V = -\frac{N_{i0} - N_i}{\sum \nu_{ij} r_j} \tag{7-52}$$

Equation (7-52) can be expressed in terms of volumetric concentration or in terms of conversions just as we did with the batch reactor. An *apparent residence time* based on feed conditions can be defined for a single-phase CSTR as follows:

$$\tau_{CSTR} = \frac{V}{q_0} \qquad N_{i0} = q_0 C_{i0} \qquad N_i = qC_i \tag{7-53}$$

In Eq. (7-53) the feed and effluent molar rates $N_{i0}$ and $N_i$ are expressed in terms of volumetric flow rates $q_0$ and $q$ (inlet and outlet, respectively) and concentrations. Thus Eq. (7-52) can be rewritten as

$$\tau_{CSTR} = \frac{C_{i0} - (q/q_0)C_i}{\sum \nu_{ij} r_j} \tag{7-54}$$

Equation (7-54) allows calculation of the residence time required to achieve a given conversion or effluent composition. In the case of a network of reactions, knowing the reaction rates as a function of volumetric concentrations allows solution of the set of often nonlinear algebraic material balance equations using an implicit solver such as the multivariable Newton-Raphson method to determine the CSTR effluent concentration as a function of the residence time. As for batch reactors, for a single reaction all compositions can be expressed in terms of a component conversion or volumetric concentration, and Eq. (7-54) then becomes a single nonlinear algebraic equation solved by the Newton-Raphson method ( for more details on this method please see Sec. 3 of this handbook or any relevant text).

A special case of Eq. (7-54) is a constant-density system (e.g., a liquid-phase reaction), with the true average residence time $\tau_{CSTR}$

$$\tau_{CSTR} = \frac{C_{i0} - C_i}{\sum \nu_{ij} r_j} \qquad q = q_0 \tag{7-55}$$

When a number of such CSTRs are employed in series, the concentration profile is step-shaped if the abscissa is the total residence time or the stage number as indicated by a typical reactant concentration profile in Fig. 7-2*c*.

## PLUG FLOW REACTOR (PFR)

In a *plug flow reactor* all portions of the feed stream move with the same radially uniform velocity along parallel streamlines and therefore have the same residence time; that is, there is no mixing in the axial direction but complete mixing radially (Fig. 7-1*c*). As the reaction proceeds, the concentration falls off with distance. A PFR can be operated under either transient conditions or steady-state conditions. In this section we limit the discussion to steady-state conditions. This eliminates the need to consider partial differential equations in time and space. We further limit the discussion to isothermal operation, which also eliminates the need for energy balance equations. Due to the radially uniform composition, the component material balances are simple ordinary differential equations with axial distance from inlet as the independent variable. An isothermal single-phase steady-state PFR in which a general reaction network takes place has the following general material balance equation:

$$\frac{dN_i}{dV} = \sum \nu_{ij} r_j \qquad N_i = N_{i0} \qquad \text{at } V = 0 \tag{7-56}$$

Note the similarity between the ideal batch and the plug flow reactors, Eqs. (7-45) and (7-56), respectively. In terms of conversion, Eq. (7-56) can be written as

$$N_{i0} \frac{dX_i}{dV} = -\sum \nu_{ij} r_j \tag{7-57}$$

Equation (7-57) can be integrated to calculate the reactor volume required to achieve a given conversion $X_i$:

$$V = -N_{i0} \int_{X_{i0}}^{X_{if}} \frac{dX_i}{\sum \nu_{ij} r_j} \tag{7-58}$$

An *apparent residence time* based on feed conditions can be defined for a single-phase PFR as follows:

$$\tau_{\text{PFR}} = \frac{V}{q_0} \tag{7-59}$$

Equation (7-58) becomes

$$\tau_{\text{PFR}} = -C_{i0} \int_{X_{i0}}^{X_{if}} \frac{dX_i}{\sum \nu_{ij} r_j} \tag{7-60}$$

Equation (7-60) is similar to that of the ideal batch reactor, Eq. (7-47), and the two reactor systems can be modeled in identical fashion.

For a constant-density system with no change in number of moles, the true residence time $\tau_{\text{PFR}}$ is

$$\tau_{\text{PFR}} = \int_{C_{i0}}^{C_{if}} \frac{dC_i}{\sum \nu_{ij} r_j} \tag{7-61}$$

This is identical to the corresponding ideal batch reactor, Eq. (7-49).

**Ideal Recycle Reactor** All reactors can sometimes be advantageously operated with recycling part of the product or intermediate streams. Heated or cooled recycle streams serve to moderate undesirable temperature gradients and they can be processed for changes in composition, such as separating products to remove equilibrium limitations, before being returned to the reactor. Say the recycle flow rate in a PFR is $q_R$ and the fresh feed rate is $q_0$. With a fresh feed concentration of $C_0$ and a product concentration of $C_2$, the composite reactor feed concentration $C_1$ and the recycle ratio $R$ are

$$C_1 = \frac{C_0 + RC_2}{1+R} \qquad R = \frac{q_R}{q_0} \tag{7-62}$$

The change in concentration across the reactor becomes

$$\Delta C = C_1 - C_2 = \frac{C_0 - C_2}{1+R} \tag{7-63}$$

Accordingly, the change in concentration (or in temperature) across the reactor can be made as small as desired by increasing the recycle ratio. Eventually, the reactor can become a well-mixed unit with essentially constant concentration and temperature, while substantial differences in composition will concurrently arise between the fresh feed inlet and the product withdrawal outlet, similar to a CSTR. Such an operation is useful for obtaining experimental data for analysis of rate equations. In the simplest case, where the product is recycled without change in composition, the reactor equation at constant density for a PFR with recycle is

$$\tau_{\text{PFR}} = (1+R) \int_{C_{i0}}^{C_{if}} \frac{dC_i}{\sum \nu_{ij} r_j} \tag{7-64}$$

Since $1 + R > 1$, recycling increases the residence time or reactor size required to achieve a given conversion.

## EXAMPLES FOR SOME SIMPLE REACTIONS

Table 7-2 and Figs. 7-3 and 7-4 show the analytical solution of the integrals for two simple first-order reaction systems in an isothermal constant-volume batch reactor or plug flow reactor. Table 7-3 shows the analytical solution for the same reaction systems in an isothermal constant-density CSTR.

Section 19 discusses the advantages and disadvantages of CSTRs versus PFR and BR for various reaction systems.

**TABLE 7-2 Consecutive and Parallel First-Order Reactions in an Isothermal Constant-Volume Ideal Batch or Plug Flow Reactor**

The independent variable $t$ is either the batch time or the plug flow residence time.

| Reaction network | Material balances | Concentration profiles |
|---|---|---|
| $A \xrightarrow{1} B \xrightarrow{2} C$ | $\frac{dC_a}{dt} = -k_1 C_a$ | $C_a = C_{a0} e^{-k_1 t}$ |
| | $\frac{dC_b}{dt} = k_1 C_a - k_2 C_b$ | $C_b = C_{b0} e^{-k_2 t} + \frac{k_1 C_{a0}}{k_2 - k_1} (e^{-k_1 t} - e^{-k_2 t})$ |
| | $\frac{dC_c}{dt} = k_2 C_b$ | $C_c = C_{a0} + C_{b0} + C_{c0} - C_a - C_b$ |
| $A \xrightarrow{1} B$<br>$A \xrightarrow{2} C$ | $\frac{dC_a}{dt} = -(k_1 + k_2) C_a$ | $C_a = C_{a0} e^{-(k_1 + k_2) \tau}$ |
| | $\frac{dC_b}{dt} = k_1 C_a$ | $C_b = C_{b0} + \frac{k_1 C_{a0}}{k_2 + k_1} (1 - e^{(k_1 + k_2) \tau})$ |
| | $\frac{dC_c}{dt} = k_2 C_a$ | $C_c = C_{a0} + C_{b0} + C_{c0} - C_a - C_b$ |

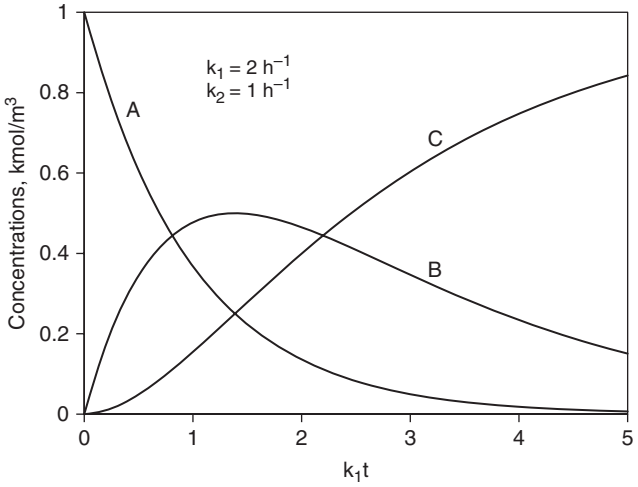

**FIG. 7-3** Concentration profiles for the reactions $A \rightarrow B \rightarrow C$.

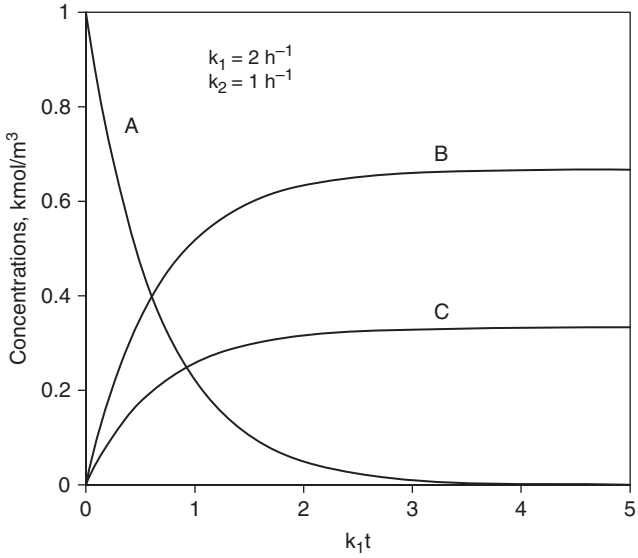

**FIG. 7-4** Concentration profiles for the reactions $A \rightarrow B$ and $A \rightarrow C$.

**TABLE 7-3 Consecutive and Parallel First-Order Reactions in an Isothermal Constant-Volume Ideal CSTR**

| Reaction network | Material balances | Concentration profiles |
|---|---|---|
| $A \overset{1}{\Rightarrow} B \overset{2}{\Rightarrow} C$ | $C_{a0} - C_a - \tau k_1 C_a = 0$ | $C_a = \dfrac{C_{a0}}{1+\tau k_1}$ |
| | $C_{b0} - C_b + \tau(k_1 C_a - k_2 C_b)$ | $C_a = \dfrac{C_{b0}}{1+\tau k_2} + \dfrac{\tau k_1 C_{a0}}{(1+\tau k_1)(1+\tau k_2)}$ |
| | $C_{c0} - C_c + \tau k_2 C_b = 0$ | $C_c = C_{a0} + C_{b0} + C_{c0} - C_a - C_b$ |
| $A \overset{1}{\Rightarrow} B$<br>$A \overset{2}{\Rightarrow} C$ | $C_{a0} - C_a - \tau(k_1 + k_2) C_a = 0$ | $C_a = \dfrac{C_{a0}}{1+\tau(k_1+k_2)}$ |
| | $C_{b0} - C_b + \tau k_1 C_a = 0$ | $C_b = C_{b0} \dfrac{\tau k_1 C_{a0}}{1+\tau(k_1+k_2)}$ |
| | $C_{c0} - C_c + \tau k_2 C_a = 0$ | $C_c = C_{a0} + C_{b0} + C_{c0} - C_a - C_c$ |

## KINETICS OF COMPLEX HOMOGENEOUS REACTIONS

Global or complex reactions are not usually well represented by mass action kinetics because the rate results from the combined effect of several simultaneous elementary reactions (each subject to mass action kinetics) that underlie the global reaction. The elementary steps include short-lived and unstable intermediate components such as free radicals, ions, molecules, transition complexes, etc.

The reason many global reactions between stable reactants and products have complex mechanisms is that these unstable intermediates have to be produced in order for the reaction to proceed at reasonable rates. Often simplifying assumptions lead to closed-form kinetic rate expressions even for very complex global reactions, but care must be taken when using these expressions since the simplifying assumptions are valid over limited ranges of compositions, temperature, and pressure. These assumptions can fail completely—in that case the full elementary reaction network has to be considered, and no closed-form kinetics can be derived to represent the complex system as a global reaction.

Typical simplifying assumptions include

- *Pseudo-steady-state* approximation for the intermediates; i.e., the concentration of these does not change during reaction
- Equilibrium for certain fast reversible reactions and completion of very fast irreversible steps
- *Rate-determining step*(*s*); i.e., the global reaction rate is determined by the rate(s) of the slowest step(s) in the reaction network composing the overall or global reaction

These simplifying assumptions allow elimination of some reaction steps, and representation of free radical and short-lived intermediates concentrations in terms of the concentration of the stable measurable components, resulting in complex non–mass action rate expressions.

Complex reactions can proceed through *chain* or *nonchain* reaction steps. In a *chain reaction*, the active unstable components are produced in an *initiation* step and are repeatedly regenerated through *propagation* steps, and only a small fraction of these are converted to stable components through a *termination* step. Free radicals are examples of such unstable components frequently encountered in chain reactions: free radicals are molecular fragments having one or more unpaired electrons, are usually short-lived (milliseconds), and are highly reactive. They are detectable spectroscopically, and some have been isolated. They occur as initiators and intermediates in such basic phenomena as oxidation, combustion, photolysis, and polymerization. Several examples of free radical mechanisms possessing nonintegral power law or hyperbolic rate equations are cited below. In a *nonchain reaction,* the unstable intermediate, such as an *activated complex* or *transition state complex*, reacts further to produce the

products, and it is not regenerated through propagation but is continually made from reactants in stoichiometric quantities.

## CHAIN REACTIONS

**Phosgene Synthesis** The global reaction $CO + Cl_2 \Rightarrow COCl_2$ proceeds through the following free radical mechanism:

$$Cl_2 \Leftrightarrow 2Cl\bullet$$

$$Cl\bullet + CO \Leftrightarrow COCl\bullet$$

$$COCl\bullet + Cl_2 \Rightarrow COCl_2 + Cl\bullet$$

Assuming the first two reactions are in equilibrium, expressions are found for the concentrations of the free radicals Cl• and COCl• in terms of the species CO, $Cl_2$, and $COCl_2$, and when these are substituted into the mass action rate expression of the third (rate-determining) reaction, the rate becomes

$$r_{COCl_2} = k(CO)(Cl_2)^{3/2} \tag{7-65}$$

**Ozone Conversion to Oxygen in Presence of Chlorine** The global reaction $2O_3 \overset{Cl_2}{\Rightarrow} 3O_2$ in the presence of $Cl_2$ proceeds through the following sequence:

$$Cl_2 + O_3 \Rightarrow ClO\bullet + ClO_2\bullet$$

$$ClO\bullet + O_3 \Rightarrow ClO_2\bullet + O_2$$

$$ClO_2\bullet + O_3 \Rightarrow ClO_3\bullet + O_2$$

$$ClO_3\bullet + O_3 \Rightarrow ClO_2\bullet + 2O_2$$

$$ClO_3\bullet + ClO_3\bullet \Rightarrow Cl_2 + 3O_2$$

The chain carriers ClO•, $ClO_2$•, and $ClO_3$• are assumed to attain pseudo-steady state. Then,

$$r_{O3} = k(Cl_2)^{1/2}(O_3)^{3/2} \tag{7-66}$$

**Hydrogen Bromide Synthesis** The global reaction $H_2 + Br_2 \Rightarrow 2HBr$ proceeds through the following chain of reactions:

$$Br_2 \Leftrightarrow 2Br\bullet$$

$$Br\bullet + H_2 \Leftrightarrow HBr + H\bullet$$

$$H\bullet + Br_2 \Rightarrow HBr + Br\bullet$$

Assuming pseudo-steady state for the concentrations of the free radicals H• and Br•, the global rate equation becomes

$$r_{HBr} = \frac{k_1(H_2)(Br_2)^{1/2}}{k_2 + k_3(HBr)/(Br_2)} \tag{7-67}$$

Here the constants $k_1$, $k_2$, and $k_3$ are combinations of the kinetic parameters of the elementary steps.

**Chain Polymerization** For free radical polymerization, the following generic mechanism can be postulated:

| | | | |
|---|---|---|---|
| $I\bullet \xrightarrow{fk_d} 2R\bullet$ | | | initiation |
| $R\bullet + M \xrightarrow{k_i} P_1\bullet$ | | | |
| $P_n\bullet + M \xrightarrow{k_p} P_{n+1}\bullet$ | $n,m = 1,2,\ldots$ | | propagation |
| $P_n\bullet + P_m\bullet \xrightarrow{k_{tc}} M_{n+m}$ | | | termination by coupling |
| $P_n\bullet + P_m\bullet \xrightarrow{k_{td}} M_n + M_m$ | | | termination by disproportionation |

After writing the appropriate mass balances, and assuming the rates of formation of the free radicals $R$• and $P_n$• reach pseudo-steady state, the following polymerization rate is obtained:

$$r_p = -\frac{d(M)}{dt} = k_p(M)(P) = k_p\left(\frac{2fk_d}{k_{tc}+k_{td}}\right)(M)(I)^{1/2} \qquad P = \sum P_n \tag{7-68}$$

## NONCHAIN REACTIONS

Nonchain reactions proceed through an active intermediate to the products. Many homogeneous nonchain reactions are also homogeneously catalyzed reactions (discussed below).

## HOMOGENEOUS CATALYSIS

Homogeneous catalysts proceed through an activated or transition state complex between reactant(s) and catalysts that decomposes into products. Homogeneous catalysts are dissolved in the homogeneous reaction mixture and include acids/bases, metal salts, radical initiators, solvents, and enzymes.

**Acid-Catalyzed Isomerization of Butene-1** Butene-1 isomerizes to butene-2 in the presence of an acid according to the global reaction

$$CH_3CH_2HC{=}CH_2 \overset{H^+}{\Rightarrow} CH_3HC{=}CHCH_3$$

Even though this appears to be a monomolecular reaction, it proceeds through the following mechanism:

$$CH_3CH_2HC{=}CH_2 + H^+ \overset{k_1}{\Leftrightarrow} \{CH_3CH_2\overset{H}{\overset{\wedge}{HC}}{-}CH_2\}^+ \overset{k_2}{\Rightarrow} CH_3HC{=}CHCH_3 + H^+$$

Assuming reaction 1 is in equilibrium, the reaction rate is

$$r = k_2K_1[H^+][CH_3CH_2HC{=}CH_2] \tag{7-69}$$
